The diagnosis is generally easy. The usual troubles may have to be excluded, but their differential diagnosis will have to be discussed when speaking of syphilis of the pharynx, so it need not be gone into here.

SYPHILIS OF THE PHARYNX.

The primary sore occurs in the pharynx fairly frequently and is generally located on one or other of the tonsils, the cryptic character of which lends itself to the retention and development of the poison. Seifert was able to collect 179 instances of chancre occurring in the pharynx. Of these 149 were on the tonsils and 30 were about the palate and arches. Infection seems to be generally conveyed through kissing or through the use of infected glasses, cups, tooth-brushes, pipes, &c. The symptoms may be thus tabulated:—1. Aggravated and prolonged sore-throat. 2. Painful deglutition, always referred to the affected side. 3. An indurated swelling of one tonsil. 4. A sluggish ulcer in the centre of the swelling, granular in appearance, covered with inspissated mucus, and of a greyish colour. 5. Early and unilateral swelling of the glands at the angle of the jaw, usually painless, though sometimes tender on pressure. 6. Sometimes marked febrile disturbance and headache. The diagnosis is difficult and often is not cleared up until the appearance of secondary symptoms, when the absence of a primary sore elsewhere will point to the case being one of tonsillar chancre. It may be mistaken for (1) mucous patch, (2) for epithelioma, or (3) for ulcerating gumma.

SECONDARY SYPHILIS OF THE PHARYNX.

The following manifestations of secondary syphilis are met with:—1. Erythema. 2. Mucous patches. 3 Superficial ulceration.

1. *Erythema*.—Erythema of the fauces occurs about the time of the appearance of the rash, though it sometimes precedes it. In appearance there is but little to distinguish it from ordinary sub-acute catarrh; the mucous membrane is, however, a little darker and more venous-looking than in ordinary inflammation, and there is a sharp line of demarcation between the affected and the healthy parts; the redness, too, does not extend forward on to the hard palate. Again, one often sees two crescentic patches of dusky redness, sharply defined, running up the anterior pillars and spreading over the velum, quite symmetrical, and meeting in the middle line at the junction of the hard and soft palates. This appearance is looked upon by many as almost pathognomonic of secondary syphilis, and certainly should lead to a most careful inquiry and investigation and to a sharp outlook being kept for any fresh development. Supposing these crescentic patches of dusky redness are accompanied by the slightest opalescence of the mucous membrane of the tonsils, even if only of their anterior edges or anywhere about the fauces, then the case may be diagnosed with certainty as syphilis and mercurial treatment should be commenced at once. It is not often, however, that one is called upon to diagnose syphilis from these appearances of the throat alone. The remains of a rash, or even of the primary sore, can almost always be found, and as a rule some enlargement of glands will be present which will remove all doubt. In syphilitic erythema of the pharynx there is more discomfort than real pain. Its course is protracted and it is sometimes ushered in by febrile disturbance, which renders the diagnosis doubly difficult.

2. *Mucous patches*.—The most usual time for the appearance of mucous patches of the pharynx is soon after the establishment of the rash, though they may precede the rash or appear quite late in the course of the disease. They may be seen on the tonsils, uvula, soft palate, or arches, and occasionally on the posterior wall of the pharynx. They appear as proliferations slightly raised from the surface and they vary in size from a split pea to a bean. They are covered with a bluish-white opal-coloured membrane, and are consequently called by some "opaline patches." They tend to run together and to become confluent, in which case a large area may be covered. In some cases in the earliest stages they are semi-translucent and present the appearance of a snail-track across the mucous membrane. Occasionally, again, cases are seen where the patches are much larger and resemble ordinary condylomata. Such patches present large flat elevations often standing up from the mucous membrane as much as one-eighth of an inch. They are in colour of a dirty yellowish-white and they have an uneven cauliflower-like surface. The whole of the tonsils and soft palate and even the roof of the mouth may be quite covered with them. Isolated mucous patches, seen perhaps most typically on the tonsils, are generally round and are surrounded by an areola of much inflamed mucous membrane. There are, as a rule, patches to be seen also on the buccal mucous membrane, the lips, or the tongue, as well as on the pharyngeal walls. They are very persistent and they show a great tendency to relapse; indeed, a fresh crop may appear quite late in the course of secondary syphilis. It is very important to remember that the discharge from a mucous patch is most virulently poisonous, more so than that of any other secondary manifestation, and almost as much so as that of the primary sore. Patients should be carefully warned of this fact and cautioned not to kiss others and to reserve glasses, cups, spoons, forks, pipes, &c., for their own use. I once treated a man for syphilis and before recovery he married, shortly after which I treated his wife for the same disease. Her mouth and pharynx were covered with mucous patches, and I suppose I was not explicit enough in my directions, for while she was still under treatment her sister came to me with a primary sore on the lip, which was followed by well-marked secondary syphilis. There is only one important subjective symptom of mucous patches—namely, dysphagia. This in aggravated cases is so distressing that the patient refuses food and consequently becomes ill and wasted. The diagnosis is as a rule quite easy when definite mucous patches have formed, but it is important to be able to

diagnose secondary syphilis of the pharynx in its early stages, for the sooner treatment is begun the better for the patient. The earliest sign of trouble is the appearance of small bluish white opalescent areas upon a congested mucous membrane. They are usually first seen on the anterior edge of one of the tonsils, possibly on the uvula or anterior arch, and if accompanied by the crescentic patches of erythema on the soft palate alluded to above secondary syphilis may be definitely diagnosed and treatment commenced. I lay very great stress on this opalescent appearance, for when once recognised it is an invaluable help to diagnosis, and I know of no other symptom more often overlooked than this is. Typical mucous patches seldom occur singly, but generally in groups, and very often such groups are absolutely symmetrical, which will at once suggest syphilis. Besides general treatment mucous patches should be treated locally. They may be readily induced to heal by the application of an aqueous solution of either bicyanide of mercury (10 grains to the ounce) or of chromic acid (30 grains to the ounce or more); but it is not enough just to paint it on, for if this is done the application never reaches even the surface of the mucous patch on account of the mucus covering it. Each patch must be treated separately, and before the drug is applied the surface must be thoroughly dried and freed from all secretion by means of blotting paper or absorbent cotton-wool. Two or three applications made in this way are generally sufficient. The great infectivity of the secretion must be borne in mind in carrying out this treatment. The hands should be carefully washed afterwards and the cotton-wool mops and blotting paper should be burned.

3. *Superficial ulceration.*—This is generally seen from one to three years after primary infection. It is often difficult to determine whether it should be classified as belonging to the secondary or to the tertiary period of syphilis, but pathologically it is probably due to the breaking down of a superficial infiltration of gummatous material, though the erosion of a mucous patch may also lead to ulceration. It occurs most frequently on the tonsils. In shape the superficial ulcer is round or oval, its area is limited, and its action is sluggish, and when once established it does not tend to spread either superficially or deeply. The symptoms are unimportant. There are some discomfort in the throat and some dysphagia. The diagnosis is generally easy. A superficial round or ovoid ulcer, limited in extent, sluggish in action, and not very painful, should suggest syphilis, and a general examination will usually reveal signs confirmatory of this diagnosis. Amongst the general signs I would draw attention to the almost invariable enlargement of the sub-occipital glands, and more especially to the swelling of the gland above the internal condyle of the elbow. Should this latter be found enlarged without any other obvious cause it is almost safe to form a diagnosis of syphilis. These glandular enlargements persist long after other signs of secondary syphilis have disappeared. The local treatment consists in the application of chromic acid in the same way as recommended for mucous patches.

TERTIARY SYPHILIS OF THE PHARYNX.

The following tertiary troubles are met with:—1. Gummata, (*a*) circumscribed and (*b*) diffuse. 2. Ulcerations. 3. Scars, contractions, and adhesions.

1. *Gummata.*—Just as in the nose so in the pharynx, it is very rare to see a definite gumma. Almost invariably the infiltration has commenced to break down and to ulcerate before the patient comes under observation. (*a*) Circumscribed gummata appear as swellings varying in size from a bean to a walnut and even larger. They are generally situated on the posterior wall of the pharynx or on the velum, often on its posterior surface, and sometimes on the tonsils. They are generally in the submucous tissue, though occasionally they infiltrate the mucous membrane itself. They are at first hard and somewhat ill-defined, but quickly become soft in the centre, as evidenced by the appearance of a soft yellow spot which rapidly passes on to ulceration. As a rule, gummata form, soften, and ulcerate with astonishing rapidity, though occasionally they assume a chronic form and remain as tumours for a very long period. Dr. Hunter McKenzie relates a case where there was an extensive gummatous swelling of the pharynx on its posterior wall which persisted for more than two months and was dissipated by iodide of potassium without ulcerating. Cheatle has shown a similar case before the Laryngological Society of London, and I have recently seen one at the Throat Hospital. The symptoms complained of are chiefly those which may be referred to mechanical difficulties of deglutition and phonation. There is a certain amount of aching pain, which is very often worse at night. The diagnosis is sometimes difficult, though the softening centre and the result of treatment soon clear it up. Occasionally, and especially when a tonsil is the seat of disease, there may be some difficulty in excluding malignant disease. (*b*) In diffuse gummata the posterior wall of the pharynx and the soft palate are attacked with about equal frequency. When the soft palate is attacked gummata are very commonly found, as already stated, on its posterior surface, and in consequence are often overlooked until perforation has occurred. Another variety of diffuse gummatous infiltration often attacks the lateral walls of the pharynx, causing large, red, painless swellings, generally on both sides, and very like ordinary hypertrophy, only that it is more pronounced and less painful. These swellings do not show the same tendency to soften and break down as do similar infiltrations elsewhere in the pharynx. They are very persistent, and when seen should always suggest the possibility of syphilis.

2. *Ulcerations.*—When the gummatous infiltration is in the mucous membrane proper the result of its breaking down is often a superficial serpiginous ulcer which is characteristic of early tertiary syphilis. Such ulcers are seen on the tonsils, soft palate, or anterior pillars. They are covered with dirty pus through which red granulations peep up. Sometimes there is seen, on the soft palate especially, a somewhat superficial form of ulceration, covering a large area, but taking a long time to destroy the deeper tissues and thus to cause perforation. Nevertheless, if untreated, it will in time destroy a great portion of the soft palate, though in doing so it pursues a very sluggish course. Deep crateriform ulcers are, however, the commonest form of tertiary syphilis in the pharynx. They are due, as before stated, to the breaking down of gummatous deposits. The soft palate is perhaps most commonly affected, but it attacks with almost equal frequency the posterior wall of the pharynx, whilst tertiary ulceration of the tonsils is by no means uncommon. The ulceration commences in the centre and quickly extends to the limit of the deposit. The occurrence of ulceration will greatly increase the discomfort complained of when the disease is still in the gummatous stage. The pain on deglutition becomes quite severe, and the presence of tenacious muco-pus, which is expectorated with great difficulty, is often very distressing to the patient. Directly the palate is perforated regurgitation of food and drink and alteration of the voice are complained of, and the patient's general health is apt to become much depreciated. As to diagnosis, a deep punched-out crateriform ulcer with a red areola and with its surface covered with greyish pus is characteristic of the trouble, and diagnosis should not be difficult. Occasionally the question may arise as to whether the ulceration is malignant, and sometimes, in the palate especially, the diagnosis may rest between lupus and syphilis. The single deep ulcer cannot well be mistaken for lupus, but in the more superficial type of ulceration mentioned above, which is very sluggish in its course, neither healing nor extending very rapidly, and taking a long time to cause perforation, it may be a matter of the greatest difficulty to determine whether the case is one of lupus or of syphilis. In lupus, however, the ulceration is very superficial and patchy and is surrounded by nodules characteristic of that disease. The affected area shows signs of healing in one place and of breaking down in another, and there is but little surrounding inflammation or pain, and finally, though scarring is extensive, adhesions are extremely rare. In superficial syphilitic ulceration, on the other hand, though the ulceration is not of the usual deep punched-out character, it is deeper than in lupus and there are no nodules and no attempt at healing. The ulceration is surrounded by an areola of inflamed mucous membrane, and as well as scarring there are generally adhesions.

3. *Scars, contractions, and adhesions.*—All tertiary syphilitic processes in the pharynx are followed by well-marked cicatrices when healing is established. These give the tonsils a hard lobulated appearance and the posterior wall of the pharynx a patchy or streaky look. The appearance of the soft palate varies with the extent of the disease. Sometimes the whole palate is a mass of cicatricial tissue, in which case its functions become impaired and both deglutition and articulation suffer. This is, of course, more marked when any great loss of substance has occurred. When there are large perforations

the voice assumes the cleft palate character and deglutition is, at first at any rate, very imperfect. Adhesions are a very common result of tertiary syphilis and are very important both from a diagnostic and surgical point of view. They may occur in many forms, of which the following are amongst the most common. 1. Adhesion of the posterior pillar of the fauces to the posterior pharyngeal wall, leading through cicatrisation to dragging of the uvula and palate over to the affected side. This causes practically no inconvenience as regards phonation and deglutition, but it may lead to deafness of the corresponding ear through dragging and pressure on the Eustachian tube and impairment of muscular action. 2. Unilateral adhesion of the palate to the posterior pharyngeal wall. This, again, does not cause much practical inconvenience, though it may lead to unilateral deafness in the same way as the above deformity. 3. Adhesion of almost the entire palate to the posterior pharyngeal wall. This is not at all uncommon and is sometimes the cause of much discomfort. It may result from deep ulceration of either the soft palate or the posterior wall, or both, but I think it is most common in connexion with disease of the palate. 4. Total atresia. This is fortunataly very rare, though there are a good many cases on record. The opening left, however, is often so small that the consequences may be the same as if complete closure had occurred. Such cases are accompanied by mouth breathing, complete nasal stenosis, inability to cleanse the nostrils of their secretions, loss of taste and smell, liability to attacks of laryngitis and bronchitis, and deafness. This last complication is by far the most important, for it tends to be steadily progressive and is often accompanied by attacks of the most intense earache. 5. Adhesions between the posterior pharyngeal wall and the base of the tongue. This deformity is very rare, about 30 cases only having been recorded. When they do occur the opening is often so small that it is amazing how air, and more especially food, can find their way through. Surgical treatment in these cases is sometimes absolutely necessary in order to establish an opening sufficiently large to admit of the taking of nourishment. 6. Adhesion of the velum to the base of the tongue. This again is very rare, there being only one or two cases on record.

Treatment.—In all forms of tertiary syphilis of the pharynx the combination of iodide of potassium internally and mercurial inunction is especially useful and should be employed at the earliest possible opportunity. In tertiary ulceration a good deal may be done locally to arrest the disease and to promote healing. The surface of the ulcer should be carefully cleansed and insufflated with iodoform, or in some cases with heated calomel, either of which applications will be found most useful. In cases in which there is much pain the insufflation of orthoform will be attended with results most grateful to the patient. One insufflation will often relieve pain for as long as 24 hours, so that daily application will keep the patient quite comfortable. Both nitrate of silver and chromic acid are also useful applications. The best method of applying either of them is to fuse a little of the pure drug on to a probe, and having cleansed the surface of the ulcer to paint it on. Lastly, the patient may be given for use at home a gargle composed as under: chlorate of potash, 10 grains; lotio nigra, half an ounce; water to one ounce. This is most useful for the relief of pain and for cleansing the throat. As regards the treatment of adhesions I should say that the less the operative interference the better for the patient. Universal experience teaches us that while it is easy enough to make a larger opening it is almost impossible to maintain that opening, and that the last state of the patient is likely to be worse than the first owing to re-adhesions and contractions leaving a smaller opening than before. It is, therefore, never wise to resort to operation unless there are very strong reasons for trying to relieve the obstruction, such as rapidly increasing deafness, constant and intense earache, or great discomfort to the patient arising from the nasal stenosis. Should operation be considered absolutely necessary every conceivable device will have to be tried for maintaining a larger opening. Cleverly devised plastic operations, the insertion of plugs, tubes, lint, &c., have been resorted to with occasional success, but as a rule, however great the ingenuity displayed, disappointment is only too apt to result, and of this fact the patient should be warned beforehand. From observation on a great number of cases I should say that it is most surprising how great an amount of contraction may exist and yet cause comparatively little discomfort, and that therefore it is seldom necessary to exercise the ingenuity which such cases undoubtedly require, if they have to be treated surgically. When the opening is so small as to cause symptoms it is generally sufficient to pass dilating instruments regularly and in increasing sizes in order to render the patient quite comfortable, and this the patient can be easily taught to carry out for himself.

Harley-street, W.

REMOVAL OF A FOREIGN BODY FROM THE BRONCHUS BY INTRATHORACIC TRACHEOTOMY.

BY H. MILTON, M.R.C.S. ENG.

IN THE LANCET of March 27th, 1897 (p. 872), I described a successful case of anterior median thoracic incision for a tuberculous tumour of the anterior mediastinum. I have now to record a second case in which the same operation was performed for a foreign body in the right bronchus, this time, unfortunately, with a fatal result. The different issues in the two operations were due in all probability to the fact that asepsis could be carried out in the first case, whereas in the second sepsis already existed at the time and place of operation.

The patient was a Fellah, aged about 40 years, on whom tracheotomy had been performed some years previously for syphilitic stenosis of the larynx. A short time previous to his re-admission to hospital the tubular portion of the outer silver tube had become detached from the shield and had fallen into the trachea. On admission the patient seemed in no ways incommoded except for a slight fixed pain behind the sternum. No signs could be detected by external examination and the laryngoscope showed nothing beyond the stenosis of the larynx. A long silver probe passed through the tracheotomy wound into the trachea as far as its bifurcation gave at first no indication; eventually, however, after bending its lip to the right so as to facilitate its introduction into the right bronchus a loud metallic click was produced, audible to the bystanders. During the following days many attempts were made to seize and withdraw the foreign body with various shaped forceps, blunt hooks, coin-catchers, slings, and mounted sponges without success, the patient being frequently inverted. The patient was then left some days without further interference, but his temperature began to rise and he was affected with a constant cough, accompanied by purulent expectoration, which gradually became fœtid. Examination of the chest showed that air entered both lungs freely and that there were many moist râles and bronchitic sounds over the lower half of the right lung. The gravity of his condition was explained to the patient as well as the serious nature of the operation proposed; he, however, expressed his anxiety to risk anything to obtain relief. It was evident that the tube could only be removed through a tracheal incision and that this incision could be made in three positions, either in the neck, through the anterior or through the posterior mediastinum. The opening in the neck existed already and all efforts to remove the tube through it had been unsuccessful. Of the two mediastinal routes the posterior seemed to present more technical difficulties and to offer fewer chances of reaching the foreign body; it would at the same time afford better opportunities for drainage. It was decided ultimately to follow the anterior route. The patient was chloroformed through the tracheal opening, warmed chloroform vapour being blown into it through a glass nozzle. The skin over the thorax was thoroughly cleansed and at this moment an accident occurred which was regrettable, but which did not, I think, affect the result of the operation. The soapy water from the front of the chest was allowed to run on to the front of the trachea and a small quantity of it was sucked into the tracheotomy hole. The greater part of it was expelled by coughing and by partial inversion of the patient. The anæsthetic was then re-commenced and the operation proceeded with.

An incision was made from the tracheotomy wound to the

ensiform cartilage, the skin on each side was reflected outwards, and the sternum and trachea were exposed. The tissues were then separated with the knife from the notch of the sternum, and the point of the forefinger insinuated as far down as possible on the posterior surface of the bone, displacing backwards the trachea, innominate artery, and left innominate vein. The sternum was then sawn through in the middle line, the incision commencing at the notch, where the deep structures were carefully protected by the forefinger and being gradually carried down as far as the ensiform appendage. A chisel was inserted into the incision and rotated sufficiently to allow the introduction of two powerful retractors with which the two halves of the sternum were dragged apart. The chief opposition to the separation was caused by the ligamentous fibres at the back of the sternal notch, and after their careful division with the knife the two halves could be freely separated, the distance between them at the sternal notch being fully four centimetres. The trachea was now fully exposed to the point where it was crossed by the innominate vessels, but even after these were well retracted the bifurcation could not be seen. A hook was therefore introduced into the tracheotomy opening and the trachea drawn strongly upwards; this manœuvre combined with the retraction of the vessels allowed the bifurcation to be plainly seen. An incision about 2 centimetres long was then made into the anterior wall of the trachea at the lowest part exposed—i.e., just above the bifurcation—and a teaspoonful of evil-smelling frothy mucus escaped and was carefully mopped up. The lips of the incision were drawn apart and a strong light thrown into the trachea towards the right bronchus; the hoped-for metallic gleam did not, however, appear. The little finger was then introduced and its tip inserted into the right bronchus at once impinged on the lost tube which had become blackened and practically invisible. Guided by the finger small forceps were introduced but failed to get a firm hold, the difficulty being caused by the position of the upper edge of the tube which lay imbedded in the thickened bronchial wall. Eventually the tube was made to partially rotate and was then seized and extracted without difficulty.

So far the operation had been perfectly simple and unaccompanied by difficulty or hæmorrhage. There had been no interference apparent with the circulation and respiration of the patient, and its immediate object, the removal of the foreign body, had been successfully effected. The remaining steps of the operation, the closure and drainage of the wound, were less satisfactorily performed and might easily be improved on. Before criticising them, however, it will be better to follow the operation to its completion and to give the subsequent history of the case.

Having removed the tube an attempt was made to close the tracheal wound. Owing to the depth at which this had to be carried out, and especially to the extreme tenuity of the tracheal walls between the rigid cartilages, this suture was imperfect and had been much better omitted, as the stitches could not fail to become septic. A drain of dermatol gauze was laid along the anterior mediastinum reaching up the trachea half-way to the tracheotomy opening, the gaping of the two halves of the sternum allowing of the introduction of a considerable quantity of gauze, and the skin flaps were loosely approximated with sutures. The incision immediately below the tracheotomy wound was tightly sewn up and a tracheotomy tube inserted. A dressing was applied all over the front of the thorax and neck up to the tracheotomy wound and the patient was removed to bed. His condition an hour later was excellent, his pulse was under 100, and his breathing, though shallow, was regular and not hurried. He was fully conscious and free from shock. He passed a good night and slept quietly. The next morning his general condition was good, but his temperature had risen and there had been much secretion from the tracheal wound, which had dirtied his dressings. His breathing was somewhat increased in frequency and there were moist râles in both lungs without consolidation. It was thought advisable to change the dressings on account of the contamination which had taken place. It was found that the two halves of the sternum were closely approximated, kept apart only by the edge of the gauze plug, which was tightly nipped between them. The plug was removed with great difficulty and with much pain to the patient, and vent was given to a quantity of fœtid fluid collected round the lower tracheal opening. This fluid was sponged away, the skin flaps were approximated, and the thoracic walls were supported by stopping, several wicks of gauze being introduced from the root of the neck towards the lower tracheal opening. After the dressing the patient was fairly comfortable, but towards the evening he began to show signs of heart failure, the pulse and respiration becoming very rapid and his temperature falling. Stimulants were freely administered by the mouth and hypodermically and the patient passed a fair night. The following morning the temperature was about 102° F., but the pulse and respiration remained very rapid. The dressings were changed frequently and the secretion, which remained fœtid, was sponged away from the tracheal openings. Towards evening the symptoms of heart failure became more pronounced, and in spite of free stimulation he died during the night.

Necropsy.—A post-mortem examination made shortly after death showed an acutely septic condition of the anterior mediastinum and commencing pneumonia of both lungs. There was no lesion or affection of the pleura, pericardium, or great vessels of the chest. There were two ulcers in the right bronchus from the pressure of the tube, and extreme cicatrisation of the larynx from old syphilitic changes. The fatal result of the operation must, I think, be attributed to one of two causes—(1) acute septicæmia; and (2) interference with the functions of the thoracic organs due directly to the operative lesions. The evidence is, I think, largely in favour of the first supposition. All the elements necessary for its occurrence were present, suppuration preexisted, the drainage and occlusion of the wound were imperfect, and the cellular tissue of extreme tenuity occupying the anterior mediastinum probably presented very little resistance to microbic invasion while affording a ready means of entry for the resulting toxins. To the other possible cause I shall refer later when considering the intrinsic dangers of the mediastinal operation.

Before quitting the particular case now reported it may be well to consider how its particular dangers might have been better averted. Had I to perform the operation again I should modify the procedure after the removal of the foreign body as follows. No attempt would be made to close the tracheal incision by suture, the difficulties of an effectual closure being, as already pointed out, very great. The greater part of the manubrium sterni would be removed subperiosteally, and through the large opening thus afforded a large gauze plug would be introduced down to the tracheal wound sufficiently firmly to occlude it. The two halves of the sternum would be firmly united below this opening by three or four strong silver sutures, leaving their ends projecting between the skin flaps sutured to the same extent. I would suture the skin from the tracheotomy wound down to the opening in the manubrium and occlude the whole of the sutured skin with collodion and gauze, thus rendering it very easy to maintain an effective dressing over the plug which might be changed every three or four hours.

Apart from the difficulties and dangers of any particular case it is necessary to make a careful analysis of the intrinsic dangers of anterior median thoracic section. They may be considered under four heads: hæmorrhage, shock, lesion to any vital function, and, lastly, sepsis. Of hæmorrhage there is practically no risk; no important vessel requires to be severed, and the great vessels lying below the sternum are quite easily protected. Shock has been completely absent in both my cases and there seems no reason to dread its occurrence. The vital functions which might be affected by the operation are two: circulation and respiration. In neither of my cases has the heart's action been appreciably affected and it is difficult to conceive of any wound or injury of heart or pericardium if due care be exercised. There are, however, in the immediate neighbourhood the cardiac plexuses, superficial and deep, through which pass the nerves controlling the heart's action. These plexuses lie in close relation with the arch of the aorta and are not likely to be cut or directly injured. The traumatism to which they are exposed produces no gross lesion comparable to section, and brain and spinal surgery have shown us that nervous tissues of the highest importance resist the gravest lesions short of destruction if sepsis be avoided. Cerebrum, cerebellum, and spinal cord have all proved their powers of resistance; the pneumogastric has been constantly exposed, pinched, drawn aside, and otherwise exposed to surgical insult with impunity; and the cervical sympathetic has been severed and its ganglia removed. The medulla oblongata is certainly still treated with the greatest respect, and it is, of course, possible that the thoracic plexuses so closely associated with it in the maintenance of circulation are equally sensitive to traumatism. This is a point which experience only can demonstrate, but I think it probable that

the slight traumatism to which they are of necessity exposed is not likely to affect them materially. The respiratory function can, on the other hand, hardly fail to be affected. The sternum is a very important element in the bony cage on whose movements respiration largely depends, but in neither of my cases has respiration been seriously interfered with. Ordinary respiration was perfectly well carried on by the diaphragm and it was only in spasmodic efforts such as coughing that any difficulty arose. So long as the lungs are unaffected the results of this operation on respiration need not be feared, but should pneumonia or severe bronchitis supervene the insufficiency of the expulsive efforts might gravely complicate the condition. An injury to the pleuræ at the time of operation is, of course, a possibility, but in my experience it has been very easily avoided, and did it occur it would at all events, if limited to one side, hardly produce any serious complication and the rent could be easily and at once repaired by sutures. To my mind the only real intrinsic danger of the operation is sepsis The mediastinum is occupied by very thin loose fibrous tissue, with imperfect blood-supply and probably very little vitality, affording, as before stated, very little resistance to microbic invasion and great facility for absorption. Moreover, the cardiac plexuses are very likely to be affected by septic inflammation occurring around them, much more so than by the traumatism to which they have been exposed.

Sepsis is, here as elsewhere, the great danger; every precaution must be taken to avoid its production and where it already exists to prevent its extension. The experience gained from the peritoneal cavity can help us but little here. The peritoneum is capable of dealing with a very considerable amount of septic matter, and its power of rapidly secreting large quantities of fluids makes drainage an easy matter either by tube or by gauze. In many cases of mediastinal operation it will, of course, be possible to insure asepsis and in such cases complete immediate closure of the thorax will be indicated. Where sepsis is unavoidable drainage will be necessary, and to my mind the sole difficulty of mediastinal operation lies in the provision of efficient drainage. Drainage may be attempted in three directions—forwards through the sternum, upwards to the neck, or backwards through the middle and posterior mediastina. Drainage through the sternum can only be efficiently provided through holes made for this purpose. The manubrium sterni might be removed almost entirely, the periosteum being left, or trephine holes be made when required, care being taken not to injure the internal mammary artery, which is well outside the sternal limits. Drainage holes having been provided the two halves of the sternum should be firmly reunited. Drainage through these openings might be afforded by gauze plugs or specially designed glass tubes. Drainage upwards to the neck might be sufficient in some cases, would be much simpler in its application, and would have the advantage that the sternal and skin flaps might be completely united over the gauze plug, leaving only a skin opening in the neck. Drainage backwards through the middle and posterior mediastina is quite prac icable and not so difficult as it seems at first sight. On the cadaver I have found it possible to insinuate my finger from the anterior to the posterior mediastinum and passing along the right side of the vertebræ to reach the third and fourth dorsal rib without injury to vein, nerve, or pleura, and by the resection of the rib from behind between its angle and tuberosity to create a practicable drainage route. There is, of course, considerable risk of tearing the pleura; a tear, however, in this position would be unlikely to produce any very serious effect. On the whole, I consider anterior drainage through special holes made in the sternum to be the best method, but experience only can decide the question, and undoubtedly the method employed must vary with the nature of the intervention.

The operation is not one to be performed without very evident indication or without due consideration being given to all other possible methods of relief. Until its technique is much more thoroughly worked out the operation is one that is only justifiable when life itself is in danger, when there is a good chance of being able to remove the *causus morbi*, and where no less dangerous route or method is available. Undoubtedly the splitting of the sternum affords the most perfect approach to the anterior and middle mediastina; it remains to be seen whether this approach is not all too dangerous to be admissible except in the most desperate cases.

Cairo.

A SINGULAR CASE OF EXTENSIVE DEPOSIT OF PHOSPHATE OF LIME IN THE LUNGS.

BY THEODORE FISHER, M.D., M.R.C.P. LOND.,

PATHOLOGIST TO THE BRISTOL ROYAL INFIRMARY; PHYSICIAN TO OUT-PATIENTS AT THE BRISTOL HOSPITAL FOR SICK CHILDREN.

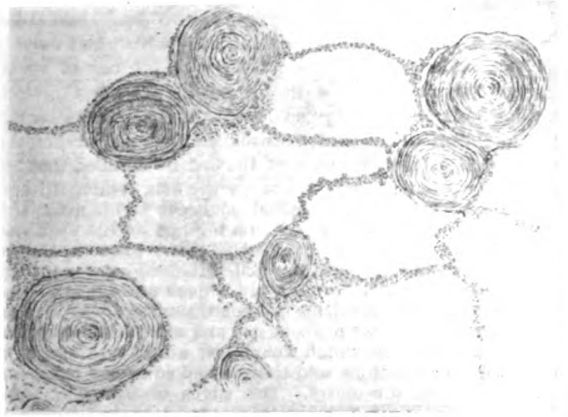
THE following case possesses some interest on account of its rarity. I have been unable to find any record of one that closely resembles it.

An unmarried woman, aged 32 years, was on June 10th, 1899, admitted into the Bristol Royal Infirmary under the care of Dr. Shingleton Smith for pneumonia and she died the same day. The following notes are abstracted from the report of the necropsy. The woman was well nourished and was of average height. Both lungs were universally adherent to the chest wall. The apices were pigmented and slightly scarred from the presence of local superficial tuberculous disease, but no fibroid or calcareous nodules were present in the thickened patches, and no old tuberculous nodules were present elsewhere over the pleuræ. The right lung was consolidated throughout. The left lung, though apparently free from recent consolidation, was abnormally resistant. Both lungs were cut with considerable difficulty and the cut surfaces presented a very unusual sensation to the touch. Everywhere they were extraordinarily gritty and small granules, in size and appearance like grains of sand, were left on the finger. Close inspection showed the substance of the lungs to be thickly studded from apex to base with these granules. In no part of either lung were they more numerous than in any other part. Both lungs were slightly pigmented and in some degree abnormally tough. The right lung was in a state of red hepatisation throughout and the lower lobe of the left lung showed some degree of commencing consolidation. The left lung may, however, be said to have been almost free from acute disease, and although almost free from consolidation the granules it contained caused it to readily sink in water. This lung weighed 45 ounces; the right lung weighed 57 ounces. In order to form a rough estimate of the amount of sand-like material in the lungs a cubic inch was cut out of one lung, and by tearing and repeated washing of this small portion most of the granules contained in it were removed. After being dried they weighed 98 grains. In drying they lost their sand-like appearance and became shrivelled and lustreless. The larynx, trachea, and bronchi were healthy. The mediastinal and bronchial glands were pigmented but presented nothing else noteworthy. The other organs showed nothing abnormal.

The following is a description of the granules and the result of analysis kindly made for me by a former pathological clerk, Dr. J. M. H. Munro: "The deposit consists of rounded transparent or translucent nodules which can be separated from the lung tissue by rasping it and washing the rasped material by elutriation or decantation with water. They are hard, fairly uniform in size, not affected by being kept in water for months, and only slightly affected by boiling-water. In a steam-oven they lose 8 per cent. of moisture but remain translucent. Under the microscope they appear to be built up of concentric laminæ, and the surfaces of many of them show markings corresponding in size and shape with the outline of pulmonary alveoli. The specific gravity is 2·325. On prolonged ignition they leave about 76 per cent. of ash which consists almost entirely of phosphate of lime. On treatment with dilute hydrochloric acid they give off a few bubbles of gas, showing the presence of a little carbonate, the phosphate of lime is dissolved out, and the concentric laminæ of organic matter become clearer in outline. The nodules answer the general tests for albuminoids and give 1·12 per cent. of nitrogen by Kjeldahl's process. Their general composition may be represented by moisture, 8 per cent.; albuminoid matter, 7 per cent.; phosphate of lime, 75·7 per cent.; non-nitrogenous organic matter, carbonates, and undetermined substances, 9·3 per cent."

Microscopical sections of decalcified portions of the left lung taken from areas apparently free from any of the lesions of acute pneumonia showed few abnormal changes. In places there was swelling with proliferation of the epithelium of the alveoli, but apart from the presence of the nodules there was

little evidence of chronic disease. The nodules generally lay in the walls of the alveoli which were of normal thickness, but here and there localised fibroid thickening was present in the immediate neighbourhood of a nodule. The outline of most of the nodules was a broad oval or slightly irregular circle. Lamination was very distinct and in most instances could be traced to the centre. Under as high a power as one-twelfth objective only in very few nodules could I trace any suggestion of a nucleus. In some a considerable portion



Calcareous granules in the lung.

in the centre appeared homogeneous, but comparison with other nodules showed gradations from this uniform appearance, through slightly marked lamination up to very definite lamination. The homogeneous aspect did not therefore appear to suggest a different origin for the central and peripheral portions of the nodules. In a few nodules small darkly-staining granules could be seen in the centre, but these were exceptional and in one or two instances at least appeared to be foreign bodies which had found their way into a central depression of the section of the nodule. The nodules stained blue with methyl aniline violet. There was no evidence that the nodules had arisen in the walls of the blood-vessels. The vessels were everywhere healthy and passed freely over the nodules without showing any connexion with them.

Inquiry into the patient's past history failed to throw any light upon the disease. She had for some years been a domestic servant and afterwards a shop assistant in a drapery establishment. Apparently her health had been moderately good. She had suffered from no serious illness, dyspnœa on exertion had not been marked, and apparently the exercise of the lungs occasioned by singing could not have caused discomfort since she was a member of a chapel choir. She had not been addicted to taking any medicine or medicinal food likely to contain phosphates.

Extensive calcification of other organs has occasionally been recorded. On mentioning this case to Dr. Rolleston he kindly drew my attention to the case of calcification of the liver recorded by Mr. Targett.[1] Another case of calcification of the liver has comparatively recently been recorded by Dr. Brill and Dr. Libman.[2] Both of these cases are. however, of somewhat different character from the above. In one the calcification occurred in large masses and in the other it was considered to have begun in the arteries. Cohnheim's Lectures on Pathology[3] contain a reference to extensive calcification of the lungs. Virchow is there quoted as saying that he has seen the lungs so infiltrated with deposits of lime salts that they felt like pumice-stone. A brief abstract of another case, recorded in *Le Mouvement Médicale*, is published in the *London Medical Record* (1879, p. 189). In this case the lungs contained 14 per cent. of lime and magnesium salts, but these salts were deposited as needle-shaped crystals, not in granules.

In this case calcification had obviously taken place in so-called amyloid bodies, and the presence of large quantities of phosphate of lime was secondary to the existence of amyloid bodies in the lungs in unusual numbers. The reason for the appearance of these bodies still seems to be in great measure a mystery. Dr. Ophüls in a recent article discusses their formation,[4] and considers them to be produced by the deposit of amyloid material around a nucleus of degenerating cells. Apparently bodies similar to amyloid bodies but of much larger size may arise by deposition of organic material around degenerating structures. I have met with a smooth ovoid mass in the mesentery of the size of a large pigeon's egg composed of layer upon layer of organic matter partially infiltrated with lime salts. In the centre of these layers was a hard, somewhat irregular, calcareous mass, without doubt a calcified lymphatic gland. Yet in the nodules from the lungs I could not detect a nucleus. If a nucleus of degenerating cells once existed it must have been small and have rapidly become absorbed at the time the first layers of amyloid material were being deposited. Although I can detect no nuclei in the nodules, that they were started by numerous localised centres of irritation seems to be as reasonable an hypothesis as any. The resemblance to acute miliary tuberculosis of the lungs is only superficial but it is in some degree suggestive. It is more easy to imagine the disease to have originated in general invasion of the lungs by some microbe of low virulence than to believe that the circumscribed morbid changes were produced by a toxin uniformly distributed through the pulmonary tissues by the blood.

In conclusion, I have to thank Dr. Shingleton Smith for permitting me to use this case and Dr. Munro for his careful analysis of the granules.

NOTES ON A CASE OF POISONING BY COAL TAR NAPHTHA.

BY G. HERBERT DOUTHWAITE, M.R.C.S. ENG., L.R.C.P., L.R.C.S. EDIN., &c.

CASES of fatal accident in which coal tar naphtha acts as the poisonous agent appear to be few and far between. The Registrar-General's report for England and Wales for 1886–95 in giving statistics regarding the relative frequency of the commoner poisons divides into the three groups—(1) poison used by suicides, (2) poison taken by accident and negligence, and (3) poisons used by murderers. Under none of these headings is there any record of naphtha poisoning. Then, again, the third edition (1896) of the "Nomenclature of Diseases drawn up by the Joint Committee appointed by the Royal College of Physicians of London" makes no mention whatever of this product. Neither is it referred to in such standard works as Brunton's "Pharmacology, Therapeutics, and Materia Medica," Hare's "Text-book of Practical Therapeutics" (1897), Taylor "On Poisons," Mann's "Forensic Medicine" (1898), &c. In the fifth and sixth editions of Guy and Ferrier's "Forensic Medicine," however, we have, in the chapter on "Inebriants," the following brief description given: "*Coal naphtha.*—This product of the distillation of coal-tar has proved fatal to a boy 12 years old. It was taken in the large dose of three ounces and death happened in less than three hours. The first symptoms were those of intoxication and furious delirium, soon followed by insensibility, stertorous breathing, and cold skin; then, after partial recovery following vomiting, fresh symptoms of collapse. Four days after death the body was pervaded by the odour of the poison."[1]

Considering. then, the comparative rarity of known cases of naphtha poisoning attended with fatal results, and acting upon the suggestion of the county coroner (Mr. J. Hyslop Bell), I venture to bring the following details of such a case under the notice of the readers of THE LANCET.

On Dec. 21st, 1900, a little girl, aged five years, was taken to bed by her mother as usual at 6 P.M. The mother at the same time carried upstairs a pint bottle filled with coal naphtha and placed it on the bedroom floor inside the door,

[1] THE LANCET, August 23rd, 1856, p. 230.

intending to put it away in a cupboard at a more convenient opportunity. She then went downstairs and with the help of a neighbour began to decorate the living-room for the approaching festive season. At eight o'clock, on her neighbour inquiring as to the whereabouts of certain illuminated texts and mottoes, she ran upstairs to her child's bedroom in order to get them out of a box in which they were kept. Her attention was at once drawn to the little girl who seemed to be breathing with extreme difficulty. Being alarmed at her condition she cried out that the child was dying. Her husband immediately ran off to procure medical assistance and came to me as the nearest practitioner. The only information that could be obtained from him concerning the nature of the case was that his daughter had gone to bed in her usual health and that now she appeared to be dying. I at once returned with the father to the house. In the meantime the neighbour, detecting the peculiar odour in the breath of the child, had drawn the mother's attention to the fact that the naphtha bottle was not now so full as before. When I arrived at the house I found my patient in an almost comatose condition, breathing rapidly and with great difficulty. There was a strong, heavy, benzine-like odour in the breath which issued from the mouth and nostrils. The face was dusky and somewhat livid and the hands were clammy and rather cold. The pupils were dilated and the conjunctiva was insensitive to the touch. The pulse was rapid and small. On carefully examining the bottle which contained what remained of the liquid I concluded that the child must have taken from between two to three ounces. After injecting a small quantity of brandy with a glass syringe into the rectum the patient seemed to revive a little and she vomited. A mixture of table-salt and warm water was then administered which caused her to vomit freely three or four times. The vomited matter smelt strongly of the poisonous liquid and consisted of partially digested food together with a quantity of frothy mucus from the air-passages. The lower extremities of the child being next immersed in a foot-bath of hot water into which a small quantity of mustard had been thrown I flicked the face with a towel dipped in cold water and also at regular intervals dashed cold water into her face. Artificial respiration was then performed and when the livid discolouration had diminished to some extent the body was inverted for a few minutes in the hope of exciting the respiratory centre in the medulla. External stimulants were also applied to the nostrils. The characteristic odour of the breath persisted for some time, which was possibly due in part to the fact that at the time of her imbibing the naphtha a certain quantity would doubtless have found its way through the glottis. The intensely laborious respiratory efforts, together with the presence of frothy mucus in the air-passages, may to some degree have been ascribed to the same cause. After the expiration of one and a half hours of continued and persistent application of restorative treatment the child regained consciousness and began to cry. A teaspoonful of brandy in sweetened hot water was then administered and I left the house, instructing the father to let me know about 11 P.M. how the patient progressed. Later in the evening I learnt from him that his daughter appeared to be going on all right and seemed somewhat inclined to sleep. On the 23rd, at about 8 P.M., both parents called at my house and informed me that they thought the child had "a touch of bronchitis." I gave them an expectorant mixture, recommended poulticing with linseed-meal and mustard, and promised to call early next morning. I examined the patient the following day and found her to be suffering from acute general inflammation of the air-passages. The mouth and throat were likewise slightly inflamed, and an eruption—resembling sordes—had now broken out on the lips. The bowels being constipated, a dose of two teaspoonfuls of castor oil was prescribed. The chest was regularly poulticed; demulcent drinks—such as milk and barley-water, &c.—were ordered, and brandy in teaspoonful doses every four hours was prescribed. The patient, however, gradually succumbed to the acute bronchitis, dying at 1.15 A.M. on Jan. 1st, 1901. An inquest followed in due course.

Coal naphtha may be readily distinguished from wood naphtha by the heavy benzine-like odour characteristic of the former. I ascertained that the child's father was employed at the corporation gas-works and was in the habit of using this product as a detergent for the purpose of removing tar from his hands.

Stockton-on-Tees.

A CASE OF ANTHRAX.

BY ARCHIBALD KIDD, M.R.C.S. ENG., L.R.C.P. LOND., D.P.H.

THE following are the brief notes of a case of anthrax which was recently under my care.

On the evening of July 4th, 1900, I was asked to visit a man who was said to have a large boil on his neck. The patient, aged 27 years, stated that he had been a little out of sorts for a week or two and had been troubled with a crop of boils on his neck which had quickly got well after the matter had been squeezed out of them. The boil for which he sought my advice was first noticed on June 30th, and on July 2nd he squeezed some matter out of it and went to his work as usual on that day and on the 3rd, though on the afternoon of the 3rd he noticed that his neck was becoming swollen, and on the 4th, feeling ill and cold, he kept his bed and applied poultices to his neck, and these, he thought, had been put on too hot as his neck was blistered. At the time of my visit (8 P.M.) his temperature was 103·4° F. and his pulse was 120. His tongue was thickly furred. He complained of pain in his neck and chest and he looked very ill. On removing the poultices there was seen on the right side of the neck, about one and a half inches below the ear, a small hole which would just admit the end of a probe and from which he said that he had squeezed out some matter two days previously. The edges of this hole were indurated and almost black in colour, and it was completely surrounded by a ring of vesicles of various sizes, the largest, which was probably formed by the confluence of smaller ones, measuring about half an inch long and being raised a quarter of an inch above the surface. The vesicles covered an area of about the size of a sixpenny-piece. The surrounding skin was of a purplish-red colour and the tissues of the neck were brawny and œdematous; the œdema extended over the right half of the chest as far as the nipple. The appearance was so striking that the probability of the case being anthrax suggested itself at once, and on inquiry I elicited the information that he worked in an office in connexion with the hide trade and was certainly exposed to the risk of becoming inoculated.

I advised an immediate operation, to which he readily consented, and I thereupon excised the area covered by the vesicles, scraped the subjacent tissues with a Volkmann's spoon, and applied pure phenol, making a circular wound about an inch in diameter. On the morning of July 5th the neck was rather more swollen and the œdema had extended and now involved both sides of the chest down to a line midway between the nipples and ensiform cartilage. His general condition, though on the whole satisfactory, was not quite so good as it was on the previous evening. On the 6th there was some improvement in the local condition. The wound in the neck was covered by a thick, black scab, and the œdema of the left side of the chest was beginning to subside; at the same time, however, the patient's general condition was distinctly worse. The temperature was 104°, the tongue was dry, brown, and tremulous, with sordes on the lips, and the pulse was 130. For the next three days his condition was very critical, the temperature ranging between 103° and 104°. The local condition, however, continued to improve, and on the evening of the 9th all œdema had gone from the left side of the neck and chest, leaving the right side still brawny and œdematous and making apparent immediately beneath the right clavicle a soft and boggy swelling with an indurated, irregular base, and on the same evening his general condition first showed signs of improvement. About a week later chloroform was administered and an incision was made into the swelling beneath the clavicle, and at the same time the scab on the neck, which was beginning to separate, was removed. His subsequent progress was uneventful, and when I last saw him in September, on his return from the seaside, the wound in the neck had healed, though that on the chest had not quite closed; otherwise he was in very good health.

The case was an extremely interesting one and for some days I had very little hope of the patient's recovery. I am inclined to think that the swelling which formed beneath the clavicle was largely gummatous in nature. It was for that reason that I delayed opening it as long as possible, and it was more the hope of relieving the pain than the

expectation of finding pus that finally decided me to do so. The result, however, was not altogether satisfactory, as though the pain was relieved only a few drops of pus were evacuated, the swelling consisting almost entirely of soft and sloughy tissue which took a long time to separate and so allow the wound to heal.

I very much regret that I was unable to confirm the diagnosis by bacteriological examination, but I think that the typical appearance of the lesion, coupled with the obvious sources of infection to which the patient was exposed, leave very little room for doubt as to the true nature of the disease. It is probable that the man became inoculated on July 2nd, when he went to work with an exposed open wound. Though the constitutional disturbance in this case appears to have been considerably greater than in either of the cases reported by Mr. E. O. Bousfield[1] and Mr. E. A. Clarke[2] the precisely similar treatment which I adopted was followed by an equally successful result as in those cases.

Ilford.

SPLENO-MEDULLARY LEUKÆMIA: REMARKABLE TOLERANCE OF ARSENIC.

BY CHARLES HEATON, M.D. BRUX., M.R.C.S. ENG., L.R.C.P. LOND.

THE notes of the following case of spleno-medullary leukæmia will be of interest at the present time in showing the remarkable way in which arsenic is tolerated by some patients. The patient came under my care in July, 1899, with the disease in an advanced condition, the blood showing typical features and the proportion of red corpuscles to leucocytes being 12 to one. He was taking liquor arsenicalis in small doses (from two to three minims) twice a day, but even this caused gastric irritation and abdominal discomfort, and had to be omitted. In consultation with Dr. H. D. Rolleston hypodermic injections were advised, beginning with $\frac{1}{60}$th of a grain of arsenious acid (this was later changed to arseniate of soda). The following were the amounts injected.

Date.	Duration of treatment.	Amount of drug administered.	Duration of intervals.
1899.			
Sept. 29th to Nov. 19th.	51 days.	4 grains arsenious acid.	—
Interval, Nov. 19th to Dec. 5th.	—	—	16 days.
Dec. 5th to Dec. 12th.	7 days.	1½ grains arsenious acid.	—
Interval, Dec. 12th to Dec. 18th.	—	—	6 days.
Dec. 18th to Jan. 2nd.	15 days.	7½ grains arseniate of soda.	—
1900.			
Interval, Jan. 2nd to Jan. 8th.	—	—	6 days.
Jan. 8th to Feb. 12th.	35 days.	28 grains arseniate of soda.	—
Interval, Feb. 12th to March 5th.	—	—	22 days.
March 5th to March 13th.	8 days.	½ grain arseniate of soda.	—
Interval, March 13th to March 21st.	—	—	8 days.
March 21st to May 1st.	41 days.	34 grains arseniate of soda and 2 grains of sodium cacodylate.	—
May 1st to May 16th.	15 days.	8¾ grains sodium cacodylate and 9 grains of sodium cacodylate by mouth.	—
May 16th to June 26th.	41 days.	35 grains arseniate of soda and 1¾ grains of sodium cacodylate by mouth.	—

The total number of days was 271, including intervals amounting to 58 days, and the total amount of hypodermic administration was as follows: arsenious acid 5½ grains, arseniate of soda 105 grains, and sodium cacodylate 10¾ grains. In addition, 10¾ grains of sodium cacodylate were administered orally. The maximum dose administered at one time was 2¾ grains of arseniate of soda, equivalent to 4 drachms 26 minims of liquor sodæ arseniatis.

The progress of the case was very carefully watched and the patient was seen in consultation by Professor W. Osler. Weekly counts of the blood were made by myself and the urine was tested for arsenic. At no time were there any objective symptoms of poisoning, no pigmentation of the skin, no evidence of neuritis, no irritation of the conjunctivæ, the subjective symptoms being restlessness and feeling of "pins and needles" in the legs, this being the indication for an interval. Mucous diarrhœa occurred latterly, but as this is a frequent concomitant of leukæmia it was probably unconnected with the treatment. The patient had suffered before the commencement of the treatment from slight eczema at the flexures of the joints and a mild but worrying herpetiform eruption of the prepuce. Both these conditions continued unaltered during the administration. The influence of the treatment was for a time apparent in the blood, as shown by the differential count, the average number of red corpuscles keeping steadily about 3,000,000 per cubic millimetre. The arsenic was rapidly eliminated in the urine, Marsh's test showing large quantities for the next 24 hours after injection and then in rapidly diminishing amounts for several days afterwards, but for exactly how long I am not able to say precisely.

The solution used for the hypodermic injections was a 1 in 500 solution of eucaine hydrochloride B, 15 minims of which contained in solution one grain of arseniate of soda. The injections were made with a very fine needle and one of Down's "all metal" syringes, holding 20 minims; with this one is able to warm the fluid to blood heat by holding the syringe over a spirit flame. If the fluid is injected cold much local irritation ensues. The solution was filtered and boiled frequently and appeared to undergo some chemical change if kept for more than a week, when it caused a little irritation and was prone to grow a mould if contaminated. With the above precautions no local trouble at the seat of injection ensued.

I found that cacodylate of soda when hypodermically administered was followed by no apparent result of any kind, but that administration by the mouth was always succeeded by a complaint of a taste of garlic and of gastric disturbance.

Westgate-on-Sea.

RESULTS OF 35 PROPHYLACTIC INJECTIONS OF THE ANTI-DIPHTHERITIC SERUM.

BY PERCY R. BLAKE, M.R.C.S. ENG., L.R.C.P. LOND.,
LATE HOUSE SURGEON TO THE NORTH-EASTERN HOSPITAL FOR CHILDREN.

RECENTLY, at the Suntrap Convalescent Children's Home, High Beech, Essex, three consecutive cases of faucial diphtheria occurred. At the time there were 38 children in the home, so after the third case developed it was deemed advisable to try the effect of prophylactic doses of antitoxin. I think the result obtained may prove interesting. I may say that the three infected children were removed immediately the diagnosis was made to the sanatorium, situated about 50 yards distant from the home. Accordingly I started the injections on Dec. 5th, 1900, when I injected 15 of the children, finishing the remaining 20 the next day, Dec. 6th. The serum used was that obtained from the Jenner Institute of Preventive Medicine, and the injection was of the quantity and strength of one cubic centimetre containing about 334 units, the prophylactic dose prescribed on the bottles. In every case the strictest antiseptic precautions were observed and the skin of the flank was the site of injection. The following were the results obtained: in no case did any local lesion follow at the site of injection; no other case of diphtheria ensued; and in 31 cases no reaction followed. The following are the notes of the remaining four cases.

CASE 1.—The patient was a boy, aged five years, suffering from rickets and chronic tuberculous peritonitis. He was injected on Dec. 5th. On Dec. 9th the sterno-mastoid glands on the right side of the neck became slightly

enlarged, hot, and tender; there was no faucial lesion and the temperature was 101° F. On Dec. 10th the temperature was 98·5°, the glandular swelling, tenderness, and heat having subsided.

CASE 2.—The patient was a boy, aged six years, suffering from early spinal caries without abscess formation. He was injected on Dec. 5th. On the night of Dec. 10th and again on the night of the 11th he complained of pain in the left knee. The joint was a little warm but there was no apparent swelling or stiffness. His temperature was never above 99° F., and after the night of the 11th he complained of no more pain.

CASE 3.—The patient was a girl, aged five years, suffering from tuberculous hip disease with ankylosis of the joint. She was injected on Dec. 6th. On Dec. 9th she developed a scarlatiniform eruption all over the trunk, arms, legs, and face. Her temperature was 100° F. The child did not complain of feeling ill and the rash was evidently unirritating. On Dec. 10th the rash was only apparent on the thighs and abdomen. Her temperature was 99 6°. On Dec. 11th the rash had quite gone. Her temperature was 98·5°.

CASE 4.—The patient was a boy, aged five years, suffering from early tuberculous hip disease. He was injected on Dec. 6th. On Dec. 14th he developed a papulo-macular eruption on the abdomen, chest, and arms. His temperature was 98 6° F. I had no further opportunity of watching his progress.

The results obtained from these prophylactic injections are certainly encouraging. The three infected children undoubtedly contracted the disease from one another, but after the injections no further cases developed. The occurrence of antitoxin phenomena after quite small doses of antitoxin is also interesting to note.

ELTHAM COTTAGE HOSPITAL.

A CASE OF PERFORATION OF THE STOMACH DUE TO GASTRIC ULCER; OPERATION, RESULTING IN RECOVERY.

(Under the care of Dr. J. D. RICE.)

THERE are three varieties of perforation in gastric ulcer. In the ordinary form an opening exists which is large enough to permit extensive extravasation of the stomach contents so that a general virulent peritonitis is rapidly set up. In a second form the extension of inflammation from the ulcer leads to the formation of numerous adhesions, limiting the extravasation which occurs subsequently, so that the peritonitis induced is confined to a small area, and a localised abscess results. In the third variety the perforation is minute, so that, although a general peritonitis is set up, it is not necessarily virulent in character, and the opening itself is soon closed by the effusion of plastic lymph. To this class the following case probably belongs. The virulence of a peritonitis varies greatly and is dependent on the form of micro-organism present. In all cases of peritonitis a bacteriological examination of the exudation is desirable.

On July 7th, 1900, Dr. J. D. Rice was asked to see a girl, a domestic servant, who had arrived from a distance in a vehicle and was said to be dying. He found she had such acute pain in the abdomen that she dared not cry out on account of the agony which it caused. Her temperature was 103° F., the pulse was 130, and the respirations were 24. Her history was as follows. For some time she had had pains in her stomach, with vomiting, accompanied by great pain, which always occurred after taking food. The ingestion of fluids alleviated the pain provided sickness was not caused. The vomited material she described as tasting sour; it occasionally contained blood, but never in great quantity; her bowels were irregular On the morning of July 6th she went to a medical man who gave her some medicine and some advice about her food. At 7 P.M. the same day she had an attack of sickness, during which she felt "something give way with a snap in her inside." The pain caused was so severe that she fell on the kitchen floor and lay there moaning until she was discovered after some time. As she believed herself to be dying the medical man whom she had seen that morning was sent for; he ordered her to bed and advised that her relatives be communicated with. They sent her to see Dr. Rice on the morning of July 7th.

On examination the abdomen was found to be distended, rigid, and immobile; it was painful to pressure on the epigastrium but not elsewhere. The liver dulness was absent. The patient refused to inspire deeply on account of the pain. Recognising the probability of a perforating gastric ulcer Dr. Rice suggested to her relatives that she should enter the hospital in order to undergo an operation as her home was by no means antiseptic. After two hours' deliberation they consented and she was removed to the Eltham Cottage Hospital at 8.30 P.M. Her temperature before removal was 104° and on arrival it was 102°. She was then rather collapsed and verging on the unconscious.

Mr. A. S. St. John and Mr. H. Sandford Smith saw the girl in consultation with Dr. Rice and confirmed his diagnosis, and he therefore decided to operate at once. Mr. St. John gave the A.C.E. mixture and Dr. Rice opened the abdomen in the middle line by an incision six inches in length. All bleeding points were secured by forceps. On opening the peritoneum in the usual way Dr. Rice thought that free gas escaped, though Mr. Smith was not of the same opinion. The stomach presented in the wound. Hot antiseptic sponges were placed round it and there was an escape of fluid which only differed from normal peritonitic fluid in containing some white flocculent particles. Contrary to expectations, on examining the stomach inch by inch no perforation was found, but a portion of its anterior surface was fixed by very fragile adhesions of lymph to the abdominal peritoneum. These adhesions, Dr. Rice believed, occluded the perforation, and as the patient was then breathing badly it was necessary to finish the operation rapidly. Hot saline solution was injected into the sub-mammary tissue and a hypodermic injection of ether and strychnine was given. The abdominal viscera were flushed with a solution of mercuric iodide and were sponged as dry as possible. The peritoneum was closed with interrupted silk sutures. The portion near the adherent stomach being partially digested gave way if any strain were put on the sutures. The abdominal wall was closed by strong silk passing through all its layers. No drain was used. The wound was dressed with iodoform gauze.

At 1 A.M. on the following morning the patient had recovered from the shock of the operation. The temperature had fallen to 100°, the pulse was 110, and the respirations were 20. The patient had an uninterrupted convalescence; on only one occasion did her temperature rise above 100°. She was nourished by nutrient enemata for six days and the wound was dressed on the sixth day. It healed by first intention. After four weeks she was discharged cured and went to a convalescent home. On Oct. 29th she was in perfect health and had no digestive troubles.

Remarks by Dr. RICE.—The points of interest in this case are that adhesions formed in about 27 hours of sufficient strength to occlude the perforation, and that operative interference in an apparently moribund patient prevented a general peritonitis which would doubtless have proved fatal.

ROYAL BERKSHIRE HOSPITAL, READING.

A CASE OF JEJUNAL INTUSSUSCEPTION; MULTIPLE GROWTHS IN THE JEJUNUM AND DUODENUM; LAPAROTOMY; DEATH; NECROPSY.

(Under the care of Dr. W. J. MAURICE.)

THE occurrence of intussusception in an adult is very rare, and it is in the majority of the cases associated with the presence of a new growth. Usually the new growth is at the apex of the intussusception, but sometimes it is found above the invagination,[1] and in these cases it may give rise

[1] THE LANCET, May 7th, 1892, p. 1028.

to the intussusception either by causing obstruction of the intestine or by interfering with the progress of peristalsis. For the notes of the case we are indebted to Mr. Arthur Stanley Green, late house surgeon.

A woman, aged 23 years, was on Feb. 10th, 1900, admitted into the Royal Berkshire Hospital under the care of Dr. W. J. Maurice. For a lengthened period the patient had been suffering from anæmia, vomiting after food, and vague pains in the region of the stomach. At 7 A.M. on Feb. 10th she was awakened by a pain in the epigastric region which was so severe that on attempting to stand she immediately fainted. She was seen very soon afterwards by Dr. J. A. P. Price, who gave her a small dose of morphia. At 12 noon Dr. Maurice saw the patient in consultation with him and it was decided to remove her to the hospital and to operate if her condition did not improve. On admission at 3.15 P.M. the pulse was rapid and small, the respirations were costal, and the abdominal wall was so rigid that nothing could be determined by palpation. The patient stated that her bowels had been opened on the previous evening.

The operation was commenced at 4 P.M. A median incision from the ensiform cartilage to the umbilicus (this was afterwards enlarged) revealed a purple-coloured tumour extending from just below the margin of the right lobe of the liver obliquely across the spinal column to the left sacro-iliac articulation; this proved to be a large intussusception of the jejunum. Very little difficulty was experienced in reducing the invaginated gut, which, although very dark purple in colour, immediately commenced to improve under warm sponges wrung out of saline solution. While returning the gut a small polypoid growth of about the size of a walnut was felt in the lumen of the bowel just above the intussusception; this was excised and the aperture was closed with two rows of silk sutures. The abdominal incision was sutured in three layers. The patient stood the operation well.

On Feb. 11th the patient had passed a comfortable night and was free from pain, but her pulse varied between 130 and 160 and she complained very much of thirst. On the 12th she said that she felt much better. She was quite comfortable during the day, but at 10.15 P.M. she had a severe pain in the left iliac region which she described as being exactly like her previous seizure. The abdomen was distended, tympanitic in front and dull in the flanks; the pulse was very rapid and small. As it was thought probable that either the intussusception had recurred or that leakage had taken place from the line of sutures in the bowel the patient was taken to the theatre and the abdomen was again opened. A considerable quantity of fluid escaped; the portion of intestine which had been invaginated was red and œdematous and the gut above was very much distended. There was no diffused peritonitis and the line of suture in the intestine (where the polypus was removed) was quite sound and had not leaked. The peritoneal cavity was flushed with sterilised water and the abdominal wound was closed. The patient died at 3 30 A.M.

Necropsy.—At the post-mortem examination it was found that the portion of intestine which had been invaginated was quite black and very much swollen; it was the upper portion of the jejunum 34 inches from the pylorus and was 14 inches in length. Ten polypi were found in the lumen of the bowel; the lowest was just above the intussusception and the uppermost was just below the pyloric opening. These polypi were all attached by thin pedicles to the valvulæ conniventes of the intestine, the point of attachment in the majority being nearly opposite the mesentery. They varied in size from that of a millet seed to that of a small walnut, the larger being lobulated; the surface of the small growths was quite smooth. Histologically they proved to be papillary adenomata.

Remarks by Mr. GREEN.—The principal features of interest in the above case are as follows:—1. The age and sex of the patient. The late Dr. Hilton Fagge[1] says: "In adults, however, it (i.e., intussusception) is infinitely more rare than might be supposed from the comparatively numerous cases that Hutchinson, Peacock, and others have collected from different medical works. Dr. Wilks used to say that he had only seen one case in a grown-up person." Intussusception is more common in males at all ages than in the female, the proportion being about two and a third to one (Dr. R. D. Brinton[2]). 2. The position of the invagination. Although enteric intussusception is much more common in adults than in young children the most frequent seats are the upper and lower portions of the ileum, only 4 per cent. being jejunal. Dr. Hale White[3] reports a case in an adult in which the invagination commenced two feet six inches from the pylorus and says: "It is very rare to get an intussusception in an adult; it is very rare for it to occur in the upper part of the jejunum and rarer for it to be due to a polypus." Dr. Thomas Peacock[4] records a case, in an adult female, in which the upper part of the jejunum formed the seat of the invagination. 3. The number and position of the growths. Cases in which a single innocent pedunculated tumour has been found in the small intestine are numerous, but I cannot find any record of a case where the pedunculated growths were so numerous and situated so high up in the alimentary canal as they were in this case. Leichtenstern,[5] in 128 cases of intestinal polypi, found that five (3·95 per cent.) were jejunal and two (1·5 per cent.) duodenal, but he does not mention whether they were single or multiple. Kanthack and Furnival[6] recorded a case of multiple polypi in the duodenum and jejunum, but they were very small in size. Mr. Treves,[7] speaking of intestinal polypi, says: "About 80 per cent. are met with in the rectum, next in frequency come the ileum and colon. They are rare in the jejunum and still rarer in the duodenum." I think it hardly possible to doubt that although the lowest polypus was not found at the apex of the intussusceptum as is usually the case, these growths were the indirect if not the direct cause of the invagination. I am indebted to Dr. Maurice for permission to publish this case.

Medical Societies.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

Better Housing of Rural Populations.

A MEETING of this society was held on Jan. 11th, Dr. J. C. MCVAIL, the President, being in the chair.

Mr. C. E. PAGET, medical officer of health of the County Council of Northamptonshire, read a paper on the Better Housing of Rural Populations. The question of the housing of the labouring classes was, he said, everywhere closely bound up with economic considerations. They were at present confronted by a high degree of commercial prosperity in the towns and an unprecedented depression of agricultural industry, the consequences of which were seen in the flow of population into the towns, where the substitution of business premises for dwellings led to the crowding of the poor into tenements ill adapted for the purpose. The success of the erection of blocks of flats and the establishment of cheap trains connecting with suburban districts in providing a remedy depended on such complex conditions as not infrequently to create new evils. It might be thought that the depletion of the rural population to the minimum required for the culture of the land would facilitate the housing of the agricultural labourers, but the depreciation of cottage property led to such neglect of repairs as too often to necessitate abandonment or demolition. In the final report of the Royal Commission on Labour in 1894 Mr. Little classified the ownership of cottage property as (1) land-owners who provided cottages for all or some of the labourers working on their estates; (2) private owners letting the cottages at the best rents they could obtain; (3) lease-holders or life-owners; and (4) occupying owners. The first class were, as a rule, satisfactory in character though rarely sufficient in number. The second class were less satisfactory, and if the owner had not an independent source of income they were no better than those of the lease- or life-holder, which were the worst of all, except, perhaps, the few owned by the labourers themselves, and for the most

part erected by squatters on waste lands with insecure tenure. Dr. G. Wilson, the medical officer of health of Mid-Warwickshire, in a house-to-house survey some 25 years ago, reported that in many villages from 15 to 20 per cent. of the cottages had but one sleeping-room and 50 per cent. had only two, the worst being those which had drifted into the hands of impecunious owners. In the eastern and midland counties the villages were "open" or "close," the latter being the property of the land-owner on whose estates the tenants were permanently employed; but there were times when additional labour was required, and this led to the growth of "open" villages with a number of owners. The more accessible these villages were the more rapid was their growth and the worse, as a rule, were their sanitary conditions. The motives that prompted the creation of the "close" village were not always philanthropic or æsthetic, for prior to the passing of the Unions Chargeability Act in 1865 each parish had a direct interest in keeping down the number of resident labourers who in their old age would have to be maintained by the rates. This was easy when the whole belonged to a single owner, but where the land was in the hands of a number of small proprietors each sought to make a personal profit by the erection of cottages at the lowest possible cost for construction or maintenance, and Mr. Paget described the state of one such village in his district, in which 11 per cent. of the cottages were condemned as unfit for human habitation and 16 per cent. of the remainder were insanitary and overcrowded. A representation by the local authority, followed by an inquiry by the County Council and a recommendation for the adoption of Part III. of the Housing of the Working Classes Act, fell through at last from the reluctance alike of the parish and the rural district to bear the expense, though the necessity was admitted by all parties, while the impossibility of closing even the worst of the cottages was clear, for to do so would render the tenants homeless or aggravate the overcrowding of the rest. Coming, then, to the principles involved in the provision of houses for the labouring classes at the cost of the public, he believed that it was under certain circumstances justifiable, indeed necessary; it should not be done recklessly, but it should not be less easy in rural than in urban districts. The Housing Acts were not opposed to it when the need for *bonâ fide* agricultural labourers' cottages was palpable, and there was no probability of the need being met by private enterprise. On the other hand, the influence of the present system of outdoor relief in the maintenance of the worst class of dwellings should not be ignored, and while a local authority was acting rightly in providing cottages for the hard-working labourers who could not pay remunerative rents, they were not justified in fostering pauperism, nor should they, in his opinion, draw on public funds to a greater extent than would be required for the maintenance of the same poor under the Poor-law authority. He was pleased to observe that Section 63 of the Act of 1890, disqualifying for tenancy persons in receipt of relief other than medical, had not been repealed. The instance which he had quoted well illustrated the tedious procedure hitherto involved in the adoption of Part III. by rural authorities, and often, as in that case, with no result, although the need for it was admitted by all the authorities concerned. The Act of 1900 was intended to simplify the proceedings. He wished that it had done more in this direction, but the only evident advantages of the new procedure were (1) the repeal of Section 55 (especially the clause requiring the district council to wait until the next election before acting on the consent of the county council), and (2) the sixth section of the Act, by which if a parish council resolved that the rural district council had failed in its duty in this respect the county council, if satisfied after due inquiry as to the default, might assume the powers of the district council. He was, however, very doubtful as to any parish council taking such action, especially in the event of the cost having to be met by the parish as a contributory place. Another and most important question was whether, as a rule, the expenses of carrying out Part III. should be borne by the whole district or by the parish only. It appeared from subsection 2 of Section 55 of the Act of 1890 that the legislature was of opinion that a special case needed to be shown why the expense should not be borne by the rural district. With this view, the principle of which was involved in the Unions Chargeability Act of 1865, he was in entire agreement, the more so as the growth of insanitary "open" villages was the consequence of the selfish action of land-owners in the maintenance of "close" villages, the owners of which ought to bear their share in remedying the evils to the creation of which they had contributed. But, at the same time, there were circumstances under which he would restrict the burden to a contributory area, even more limited than the parish, as where a mining village had sprung up on its borders. Still, in most cases the parish itself was not wholly responsible, and he regretted the repeal of this subsection, since the principle of the former Act was upset by that of 1900, which seemed to give the county council or district councils no power to impose the cost of providing cottages on any area other than that for which the application was made or granted. The power of taking action hitherto confined to the district council was now shared by the parish council, the functions of the county council being still simply judicial. He was strongly of opinion that not only ought their consent to have the force of a confirmation but that they should enjoy, equally with the inferior councils, this and other powers under this matter, as they already did in the prevention of river pollution. They would then be in a position to make systematic and independent inquiries throughout their administrative areas, and to give to the work a thoroughness and uniformity which it could never acquire under the present haphazard methods.

Dr. G. REID, medical officer of health of the Stafford County Council, advocated greater powers for the county councils especially in compelling the district councils to act; the influence of the parish councils was *nil* or obstructive and their creation was a retrograde measure. The fact that the sanitary authorities were often practically the same as the boards of guardians was one cause of sanitary neglect in the rural districts, the inefficiency of the sanitary inspectors being another. He was in favour of house-building by local authorities, not that it would be generally adopted, but since it would stimulate land-owners.

Dr. J. S. TEW, medical officer of health of the West Kent combined districts, found that in many places the fear of the Act had stimulated local builders. In one village it had been adopted with such success that further building had been resolved on. In this instance it was the parish council that had taken the initiative, but Penshurst was an exceptional village.

Dr. E. C. SEATON, medical officer of health of the administrative county of Surrey, would remind the society that house sanitation was not the whole duty of county councils, who often had to incur great expenses in connexion with sewerage and water-supply, and they might, as his council had, properly refuse an application on the ground that the houses would be taken up by men from the towns.

Dr. A. NEWSHOLME, medical officer of health of Brighton, urged the equalisation of rates over wider areas. Even in Brighton the parishes of Hove and Preston were less heavily rated than was that of old Brighton. It might, he maintained, be just to build houses that would for some time be a burden on the rates, and if before demolishing condemned property the local authority erected suitable dwellings in other parts it would avoid the hardship of displacing the tenants and lessen the value and cost of acquiring the old tenements.

The PRESIDENT and Mr. PAGET made a few further remarks.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Cases of Disease of the Prefrontal Lobes.—Skiagraphy v. the Practitioner.—Exhibition of Cases, Pathological Specimens, &c.

A MEETING of this society was held on Jan. 11th, Dr. GORDON BLACK, the President, being in the chair.

Dr. T. CHURTON read a paper on Some Cases of Disease of the Prefrontal Lobes. He said that among the problems to be solved during the twentieth century there was not one surpassing in interest or in importance that of the functions of the prefrontal lobes—in interest because they were the specifically human or social lobes; in importance because they were probably always at fault in the ever-increasing number of cases of insanity; possibly also in the grosser, or even in all, forms of crime. And the consideration of their diseases was of present

practical use, for tumours had been successfully diagnosed in, and removed from, them by Durante and others. Dr. Churton proceeded to describe the anatomical limits of the lobes; the fibres which had been found degenerated after their removal; the views as to their function held by Wundt, who ascribed to them the faculty of apperception—that was, the power of selection of the ideas or mental images to be the subject of thought or attention at a given moment; and the contrary views of Lichen, who maintained that there were at least four association centres in the hemisphere and that the prefrontal lobe was merely one of them, the others being the insula, the greater part of the temporal lobe, and the posterior part of the parietal lobe. The results of removal of the lobes in animals were summarised and it was inferred from these and from cases of disease that the use or function of the lobes was briefly (1) to permit or to inhibit certain proposed acts, according to the memory of former results of such acts; and (2) to excite the lower centres of sense (or their "memory-cells") and motion in the absence of external stimuli, thus acting as an internal store of accumulated stimuli. Diseases of the lobes, besides congenital defects in the cells found in some criminals, were divided into irritation disorders and depression disorders. Excessive curiosity in a boy with chorea; cases of insanity in which the attention was fixed upon one idea; hypnotism in which it was fixed upon the auditory cells receiving the suggestion of the hypnotiser, to the exclusion of all other excitations, external or internal; hysteria; and simple (volitional) malingering were included in the first division, as illustrations of disorders characterised by depression of the activity of the prefrontal cells. Cases were briefly related of (1) simple automatism due to bilateral abscess in the prefrontal region; (2) a similar case, but without necropsy; (3) a similar case, but with changes in "reflex" conduct also—dementia; (4) curious acts and mis-timed humour, with sarcoma in the third right frontal gyrus; (5) whimsical conduct during life—gummata in the prefrontal lobes; the age of the patient was 14 years; (6) a man, aged 27 years; humorous conduct; anosmia in the right nostril; aneurysm of anterior communicating artery invading the right lobe; and (7) a man, aged 36 years, whose symptoms appeared in the following order: in June, 1899, he could not smell flowers; in February, 1900, he was sleepy, blundered at work, was forgetful, and was negligent about dress. In April he lost interest in home and family. He still saluted friends and in the usual manner. In June urine and fæces were passed unconsciously and unnoticed, although he reacted normally, though rather slowly, to ordinary stimuli. In July (in hospital) he showed no curiosity or interest in anything; his replies were normal and gruffly humorous. His memory of events in his illness was fairly good but was said to be somewhat distorted. He died in September. A psammo-sarcoma as large as an orange had grown from the falx cerebri, compressing both prefrontal lobes, the left more than the right, and had passed beneath the corpus callosum; pression upon the left corpus striatum. This specimen was shown. It appeared that it was not the absence of so-called intelligent replies and other actions in response to excitations from without but the absence of spontaneity—i.e., of excitation from within—which was the distinctive sign of prefrontal paralysis.

Mr. W. H. BROWN read a paper on Skiagraphy *v.* the Practitioner, pointing out the danger to the practitioner which lurked in the discovery of the x rays and its indiscriminate use by the laity. The evils to the patient of over-exposure had already brought the "unknown quantity" x into the law courts; another person often injured was the medical attendant in cases of fracture. The public had quickly seized on so attractive a check on their medical man's work, and the patient and his friends soon tried him before the "shadow" judge. The village *savants*, in solemn conclave at the inn, guided by the light of the x ray, pronounced verdict on their medical attendant and in one case almost ruined him. Now it often happened that a limb, though not skiagrammatically perfect, was yet functionally so, but the public, as in other matters, leant rather towards what was pleasing to the eye than simply useful, and, comparing with the skiagram of the corresponding bones, judged accordingly, so that the confidence in, and perhaps practice of, the medical man was destroyed, although his treatment had produced a sound and useful limb, a result which a few years ago he would not have feared to have had proclaimed from the housetops, but which he now sought to hide under a bushel, for the evils which he did lived after him, in fact, until at length interred with his patients' bones. Continuing, Mr. Brown said that these remarks naturally suggested wiring in all cases, but he himself did not think that the time had quite yet arrived when they could with perfect safety advise an operation in every case of simple fracture, and this being so it would follow that in some cases the skiagram would reveal an asymmetrical union of bone on account of which the medical man might be charged with malpractice; it would, therefore, be wise for him in all cases to protect himself by dividing the responsibility with a neighbouring practitioner, and if possible by having the limb skiagraphed before and after "setting." Cases were then referred to when the x rays had given rise to quarrels between patients and their medical men, and at the end a large number of fractures were put on the screen which had resulted in useful limbs to their owners, though the skiagram showed no trace of beauty of outward form or grace. The x rays were good servants but bad masters; of the limits to their future development they could only speculate. With Hamlet they might say:—

> "Angels and ministers of grace defend us!
> Be thou spirit of health or goblin damned;
> Bring with thee airs from Heaven or blasts from hell;
> Be thy intentions wicked or charitable?
> Thou comest in such a questionable shape,
> Oh, answer me!
> Let me not burst in ignorance."

The following cases, pathological specimens, &c., were exhibited:—

Mr. W. R. BATES (Ilkley): A case of recovery from Tuberculous Meningitis. (The patient was shown.)

Mr. P. J. CAMMIDGE: A specimen of Blue Urine.

Mr. H. LITTLEWOOD: 1. Specimens from two cases of Perforated Gastric Ulcer. 2. Carcinoma of the Large Intestine: (*a*) removed from the splenic flexure; and (*b*) from the sigmoid, with end-to-end union. 3. Fibroid of the Cervix removed by abdominal pan-hysterectomy. 4. Papilloma removed from a Female Bladder.

Dr. A. G. BARES: (1) A case of Recovery from (?) Posterior Basal Meningitis; and (2) a Heart from a fatal case of Chorea.

Mr. B. G. A. MOYNIHAN: (1) Partial Thyroidectomy in a case of Exophthalmic Goitre (with Dr. GIRLING); (2) a specimen from a case of Anthrax; and (3) direction showing an Arterio-venous Aneurysm, resulting from a bullet-wound.

Dr. T. WARDROP GRIFFITH: A specimen of Tricuspid Stenosis.

Mr. W. H. BROWN: (1) A case of Intracranial Aneurysm following Fractured Base of the Skull; (2) Epithelioma of the Scalp removed from a patient, aged 78 years (the patient was shown); (3) a case of Fæcal Fistula following Suppurative Peritonitis; and (4) Lumbar Colotomy done six years ago for tuberculous proctitis.

Mr. MAYO ROBSON: A specimen of Malignant Disease of the Stomach (colloid carcinoma) excised. (The patient was shown.)

Dr. J. B. HELLIER: (1) Uterus with Myomata, Pyosalpinges and Ovarian Cyst removed by Abdominal Hysterectomy; and (2) Unusual case of Blighted Ovum.

Dr. E. F. TREVELYAN: (1) A case of Wasting of the Muscles of both Hands in a man, aged 28 years; and (2) a case of Choreiform Movements of Long Duration in a man, aged 40 years.

LIVERPOOL MEDICAL INSTITUTION.

Paralysis of Doubtful Diagnosis.—Exhibition of Patients and Specimens.—Uræmic Convulsions treated by Bleeding.

THE seventh ordinary meeting of this society was held on Jan. 17th, Mr. EDGAR BROWNE, the President, being in the chair.

Dr. T. GERALD GARRY read notes of a case of Paralysis in a young girl, aged 21 years, which had been diagnosed as acute anterior poliomyelitis but which he considered to be acute lead poisoning with resulting lead paralysis. The initial attack occurred 12 months previously with fever, abdominal colic, headache, severe pains in the upper limbs, and constipation. At the end of a week loss of power followed in both the upper limbs, the right arm recovered in time, but the left arm remained paralysed. The deltoid, the infra-spinatus, the triceps, the latissimus dorsi, the muscles

at the back of the right forearm, and the muscles of the thumb and index fingers in both hands were atrophied. Contractility to the faradaic and continuous currents was absent in the wasted muscles, but reaction of degeneration existed in the biceps, the supinator longus, and the flexor carpiradialis. Treatment by continuous and sinusoidal currents extended over a period of 18 months restored complete power to the left arm and increased power to the right arm. Dr. Garry commented upon the discovery of copper in solution in the distilled water in which the negative electrode was placed after use. Devergie in a case of lead arthralgy analysed the muscles and discovered a considerable quantity of lead. In view of this fact the discovery of copper in this case might possibly prove of diagnostic interest.—Dr. T. R. BRADSHAW did not think that the diagnosis of lead-poisoning was completely established. There was no evidence to show how lead could have got into the system, since although tinned fruits contained an appreciable amount of tin it was improbable that they would contain lead. Acute poliomyelitis was not excluded by the almost complete recovery, which was often out of all proportion to the extent of the initial paralysis, only a small group of muscles being permanently atrophied.

Mr. R. W. MURRAY showed two patients upon whom he had operated for Psoas Abscess due to Spinal Disease. In one case the operation was done when the child was aged four and a half years. Two incisions were made, lumbar and iliac, the abscess cavity was cleansed, and the wound was closed without drainage. It was now six years since this was done and the child was in good health, and there was no sign of recurrence of the abscess. In the other case the abscess was a large one, extending from the lumbar region to below Poupart's ligament. Three incisions were made—lumbar, iliac, and femoral—and the abscess cavity was cleansed and closed without drainage. The child was six years old at the time and now, seven years later, she was in good health and there was no sign of the abscess reforming.—Mr. F. C. LARKIN had practised this method of treatment since the publication of Mr. Barker's paper on the subject. The results were usually excellent in children.

Mr. RUSHTON PARKER showed a Warty Polypus of the Rectum removed from a woman, aged 53 years, from the front wall of the gut. The symptoms of hæmorrhage had existed for four years with eventual protrusion. The anus was dilated and the growth was easily reached and held by Doyen's clamp, cut off, and the stump closely sewn by many points of sulphurised catgut, closely and deeply placed and tied at each point, but with continuity of thread. No hæmorrhage resulted and the patient quickly recovered.—Mr. LARKIN mentioned a case which resembled the one which Mr. Parker had described.

Mr. RUSHTON PARKER also showed a patient on whom he had operated for Perforated Gastric Ulcer in less than three hours after the event. The patient was a female, aged 23 years, who had been under treatment off and on for symptoms of gastric ulcer for two years. On Nov. 27th, 1900, less than an hour after a meal, consisting of bread-and-butter, tea, and pancakes, she was seized with violent pain in the region of the stomach, pallor, coldness, and some collapse. She was seen at once by her medical attendant who, suspecting perforation, sent her into hospital with a request for immediate attention. Operation was undertaken and was completed in less than four hours after the onset of the urgent symptoms. On opening the abdomen, after prolonged search, in which the gastro-colic omentum was freely opened, a small perforation was found on the posterior wall of the stomach close to the smaller curvature near its middle. The edges were cut away and the opening was strongly sewn by a continuous suture through the mucosa and a double set through the peritoneal edges, one inclosing the other. A tube was put in for three days as a precaution. The patient made a good recovery, the wound healing without untoward incident.

Mr. RUSHTON PARKER also showed a patient upon whom he had operated by excising a Chronic Gastric Ulcer of which symptoms had existed for seven years and in which perforation had reached the inside of the peritoneal coat. The patient was a woman, aged 33 years, who had been disabled from work by pain in the back, which was constant except when she was lying down and taking only liquid diet. On Nov. 12th, 1900, exploration of the stomach revealed an inflammatory hardness in the small curvature. On opening the stomach there was felt a punched-out ulcer in the middle of the induration perforating the two inner coats. This was inspected through the opening and then excised, after which both openings were strongly closed with continuous sutures through the mucous and outer coats respectively. The abdomen was closed without a tube. The patient did well and the wound healed soundly, the greater part by first intention. A stitch abscess appeared at the end of a fortnight but it healed in a few days. The recovery was slow but satisfactory. She ate fish after a fortnight but did not tolerate meat without pain till two months after the operation.

Dr. T. R. GLYNN related a case of Uræmic Convulsions treated successfully by bleeding and saline transfusion. The patient, a man, aged 31 years, entered the Royal Infirmary with acute nephritis apparently of 10 days' duration and probably caused by alcoholism and a chill; the urine was scanty, of high specific gravity, and very albuminous but free from blood; the pulse was tense and the heart was enlarged. In spite of the administration of purgatives and diaphoretics, including the hypodermic injection of pilocarpine and the restriction of food to diluted milk, uræmic symptoms developed four days after his admission; one fit followed another, with coma, stertor, cyanosis, and contracted pupils. This condition having lasted several hours two pints of blood were removed and one pint of saline solution was injected into the connective tissue in the axilla and shortly afterwards half a pint into the rectum. The convulsions ceased and consciousness returned. He perspired freely for the first time, and on the next day he passed 46 ounces of urine, 20 ounces having been the maximum in 24 hours previously. During each of the following 10 days he passed on an average 70 ounces of urine in 24 hours; the albumin disappeared, the arterial tension decreased, the apex of the heart returned to its normal site, and he left the hospital in about a month apparently quite well. Dr. Glynn referred to other cases of uræmic convulsions which he had treated by bleeding but he held that the application of blood-letting in such cases was necessarily limited.—Dr. WILLIAM CARTER agreed as to the utility of bleeding in such cases as those mentioned by Dr. Glynn, and he instanced cases, one of which he had received into hospital nine years after a large venesection which had cut short uræmic convulsions and apparently saved life. In cases where bleeding was contra-indicated much good might often be done by a very free exhibition of oxygen. In yet others, where the atropine-like element of the complex urinary poison prevailed, the convulsions were promptly relieved by the hypodermic injection of morphia. Cases like those mentioned by Dr. Glynn were great facts, explain them how they might, and should encourage them to act under the guidance of a rational empiricism instead of fettering themselves with narrow and exclusive theories.—Dr. J. E. GEMMELL referred to those cases of uræmic convulsions associated with the puerperium and instanced several cases occurring during the last two years which he had treated by injections of saline solution into the rectum, in which he had seen marked improvement and return to consciousness, even before delivery, and in those cases occurring after delivery the injection of saline solution was also attended with good results.—Dr. N. RAW, Dr. A. S. F. GRÜNBAUM, Dr. E. T. DAVIES, Dr. H. ARMSTRONG, and Mr. J. WALKER also spoke, and Dr. GLYNN replied.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Patients.—Demonstration of Microscopical Preparations and Apparatus.—The Edinburgh Hospital in South Africa.

THE fourth meeting of this society was held on Jan. 16th, Mr. A. G. MILLER, the President, being in the chair.

Mr. F. M CAIRD exhibited four patients on whom he had performed Gastro-Enterostomy.

Dr. CHALMERS WATSON exhibited a large number of Microscopical Preparations illustrating the Comparative Pathology of Ataxia.

Dr. DAWSON TURNER demonstrated various forms of Interruptor for use with the Roentgen Apparatus.

Dr. FRANCIS D. BOYD read a paper on the Edinburgh Hospital in South Africa, with Notes on the Work, and showed a large number of excellent lantern slides illustrating the building of the Edinburgh Hospital and its fittings when complete. During the period under observation between 500 and 600 patients were admitted to the hospital

at Norval's Pont and 1800 out-patients were prescribed for. Enteric fever was the chief medical disease which was dealt with—in all over 150 cases were admitted. The onset of the disease was almost in every case identical—pain in the back of the head and in the neck and limbs; the bowels were, as a rule, constipated, diarrhœa being the exception. One marked characteristic was the extreme foulness of the mouth accompanied by inflammation of the fauces. In many cases this might be due to neglect, but it was present also in those cases which occurred amongst the hospital staff. Of the so-called pharyngo-typhoid (ulceration of the soft palate) Dr. Boyd saw only one case. Melæna occurred in two cases only; in one the attack was slight, while in the other it proved fatal in a few hours. Considering the frequency of dust-storms it was surprising to find that few of the cases exhibited affections of the upper respiratory tract. In one there was pharyngitis with aphonia, and in one œdema of the glottis which necessitated tracheotomy. Hypostatic congestion of the lungs was found in 15 per cent. of the cases. No case of true croupous pneumonia occurred as a complication and there was no case in which the pneumococcus was present in the sputum. Infarction of the lung with hæmoptysis was present in two cases and pleurisy with effusion in four cases. Hiccough was in one case a very serious and grave complication, persisting for nine days. In three cases old-standing cardiac lesions were discovered on admission. Of these cases two patients died, showing how serious a handicap such affections are in cases of enteric fever. Thrombosis was a frequent complication, occurring in 6 per cent. of the cases. As a rule it came on late in the disease, in the earliest case not showing itself until the twenty-sixth day. In these there was generally a rise of temperature with pain along the course of the vein—usually that of the leg—and œdema of the limb. In one case thrombosis of the branches of the middle cerebral artery gave rise to paralysis with aphasia. Dr. Boyd could not explain the reason of the frequency of thrombosis as a complication. It was a rare complication in America, though frequent enough in Great Britain. He did not think that it was due to the wearing of putties. Nephritis and cystitis were met with rarely and only occurred in patients who had previously had a damaged urinary tract. Relapse occurred in 5·3 per cent. of the cases, a low proportion when dealing with male patients only. There was no mortality from relapse. These relapses occurred although there was no error in feeding. Dr. Boyd thought that it was probable that re-infection took place from the mesenteric glands on subsidence of the reaction in the glands, the poison being set free as the lymph stream was re-established. The fever might be divided into three types: (1) the mild or abortive; (2) the grave; and (3) the apyrexial. Numerous cases of the mild form were seen, headache, malaise, and gastro-intestinal disturbance with mild fever lasting from five to 10 days being the symptoms observed. Of the grave type there were two distinct classes. In one the gastro-intestinal symptoms predominated, the tongue being very foul, the abdomen much distended, and nourishment being not well taken and feebly assimilated. In the fatal cases very extensive ulceration of the small intestine was found. In the second variety, which might be described as toxæmic, the rash was marked and the temperature was high while nervous symptoms predominated, the abdominal symptoms being subsidiary. Only one case of the apyrexial type was noted—in one of the members of the staff who had been inoculated. The temperature in this case only once rose to 99·4° F., being as a rule subnormal. The condition appeared to be a mild attack of enteric fever modified by inoculation. Widal's reaction test was employed in all doubtful cases and in most cases even when the diagnosis was certain. The diluting medium was either bouillon or normal saline in a dilution of 1 in 30. From three to six observations were always going on, so that a check was thus established. The culture used was from 24 to 36 hours old. In discussing the diagnosis of these cases Dr. Boyd asked, "Is there any other known condition except enteric fever under which they can be classified?" In some of their features they closely resembled Malta fever, agreeing in the mode of onset—severe headache, gastro-intestinal disturbance with splenic enlargement—but differing in that none of the cases showed the characteristic relapse. In six there was diarrhœa which was uncommon in Malta fever; in none were there fleeting articular pains so characteristic of Malta fever. Dr. Boyd did not think that these were really cases of Malta fever, but was inclined to regard them as cases of enteric fever modified possibly. In concluding thus he quite recognised the gravity of the position. If the agglutination reaction were absent in 6 per cent. of the cases in this epidemic did it not rather shake their faith in the value of this test as a diagnostic sign? This he feared was the conclusion to which he had unwillingly come. Was there, he asked, such a disease as simple continued fever? Most army medical men who had had experience assured him that there was a definite febricula which affected white people in hot climates. Civil surgeons were, on the other hand, inclined to regard all cases of simple continued fever as undiagnosed enteric fever. On analysing the 38 cases admitted to the Edinburgh Hospital in 10 no definite diagnosis could be arrived at, the patients being seedy and run down and showing no fever while in hospital, and Widal's test was negative. Dr. Boyd thought it was very probable that these were merely convalescent cases from influenza, which was a common disease in South Africa. Of the remaining 28 cases seven were undoubtedly those of mild enteric fever, Widal's test being positive in each. Four cases may have been abortive enteric fever, Widal's test being positive, but these patients had been inoculated against enteric fever, so no diagnostic evidence could be obtained from Widal's reaction. In six cases there was a history of former repeated attacks of malaria. Two other cases were due to catarrhal dysentery and the rest were clearly due to well-defined diseases. From this examination it must be concluded that simple continued fever while useful for a preliminary diagnosis could scarcely claim to be a distinct disease. As a rule, if the case were watched a more definite diagnosis could be made out. If 18 per cent. of such cases were due to enteric fever it was desirable to have more definite diagnosis, or else sanitary measures should be taken in all febrile conditions where enteric fever could not be definitely excluded. To get a satisfactory answer as to the actual value of preventive inoculation the statistics of the whole campaign would first of all have to be published. Of the staff of the Edinburgh Hospital 58 were inoculated, 27 being done once and 31 twice. In seven the inoculation produced no appreciable effect; in a smaller number there was merely slight local reaction. In the large majority, however, there was marked local and general reaction—malaise, faintness, and a rise of temperature of from 2° to 4°. Of those members of the staff who were inoculated nine developed enteric fever, one case proving fatal on the twenty-fifth day from cardiac failure. Three were very severe attacks with persistent high fever and marked abdominal or nervous symptoms; in four cases the attack was pronounced, and in one it was apyrexial. Relapse occurred in one case, complications in two (viz., pleurisy with effusion), and in one thrombosis of the veins of the legs. In the fatal case inoculation had been practised twice, as it had also in four of the milder cases. Of the soldiers admitted into hospital inoculation had been performed once in every case. 18 cases of enteric fever were observed; in these two were very severe, five were severe, and the rest were apparently modified attacks. Experience thus seemed to show that while inoculation appeared to modify the disease very severe attacks did occur in those cases in which the patient had been inoculated. He could not, however, conclude from this that inoculation had been valueless, for the attack might have been still more severe. It was very important to note that in the case of three of the members of the staff who developed enteric fever agglutinative power was absent during the early days of the fever, therefore it might with justice be concluded that it was not present at the time of infection. The effect of inoculation on the mortality could only be arrived at after years of experience and from the results of large numbers of cases. Dr. Boyd thought that the outlook for inoculation was hopeful. Could it be considered entirely free from harmful results? He thought that it could not. He had seen at least one case in which inoculation had markedly lowered the health of the individual, and some months later the patient developed enteric fever. The mortality of the cases in the hospital was 7·1 per cent. Perforation occurred in three cases; the greatest number succumbed to general exhaustion. Dysentery was a fairly common disease. Some 50 cases were treated in hospital. A number were of the catarrhal variety and about half of them were of the more severe ulcerative type. The amœba coli was rarely observed. This was the same as was

observed in other localities in South Africa. As regarded treatment, in mild or catarrhal cases sulphate of magnesia or castor oil and chlorodyne were the best remedies. In the severe or ulcerative cases the question of treatment was more difficult, but certainly magnesia sulphate should not be used. In some cases ipecacuanha *with* not *without* emetin seemed to act as a charm. In one or two cases no drug seemed to have any effect and the condition only improved when all drugs were stopped by the mouth and when morphia was given hypodermically. Dr. Boyd, in conclusion, alluded to the condition known as "soldier's heart," a large number of cases of which came under observation. It was found in men who had been engaged in arduous marching for months on end. There was no history of previous valvular defect and no arterio-sclerosis or kidney lesion. Shortness of breath and general weakness were complained of. The area of cardiac dulness was increased laterally and especially towards the right side. A systolic murmur was present at the tricuspid area, a venous pulsation in the neck, and no mitral lesion. These were evidently cases of dilatation of the right side of the heart from over-strain.

EDINBURGH OBSTETRICAL SOCIETY.

A Scheme of Fœtal Growth.—Intra-peritoneal Rupture of Ovarian Cysts.—Uterine Retraction.

A MEETING of this society was held on Jan. 9th, Dr. R. MILNE MURRAY, the President, occupying the chair.

The following motion, proposed by Professor A. R. SIMPSON and seconded by Dr. W. G. AITCHISON ROBERTSON, was passed *nem. con.*:—

That women shall now be admitted to the Fellowship of the society.

Dr. J. HAIG FERGUSON showed a Fibroid Uterus removed by Abdominal Hysterectomy.

Dr. J. W. BALLANTYNE described a Scheme (with diagrams) of Fœtal Growth, giving the averages of a large number of cases. After pointing out the rate of growth he gave the following table indicating the fœtal weight at the different months:—

Months	1½	2	3	4	5	6	7	8	9	10
Weight in ounces	½	½	1	2	8	23½	41¼	56	88	120

The figures showed a great increase in weight between the fourth and fifth months, when the fœtus quadrupled its weight. In the succeeding month it also grew very rapidly, nearly trebling its weight. After that its growth was not so rapid. The averages for the placenta were as follows:—

Months	3	4	5	6	7	8	9	10
Weight in ounces	¾	1⅝	6½	9$\frac{3}{10}$	13$\frac{1}{10}$	15½	16¼	16$\frac{8}{10}$

Here the placenta markedly increased also between the fourth and fifth months, quadrupling its weight, as did the fœtus. During the next month it only added half to its weight. During the last three months it was practically stationary, so that during the last three months, at least, the placenta must mainly be a transmitter of nourishment to the increasing fœtus.

Dr. F. W. N. HAULTAIN read a paper on Intra-peritoneal Rupture of Ovarian Cysts, with special reference to operative treatment. After giving details of six cases he remarked that in the majority of cases rupture was apparently unassociated with discomfort and it was therefore only in those cases where the cysts had been of sufficient size to have attracted attention that any knowledge of such occurrences could be elicited. The absence of symptoms was doubtless due to the innocuous contents of the cyst and to their slow escape, a sudden gush being prevented by intra-abdominal pressure, the peritoneal cavity being merely potential. The largest proportion of recorded cases were those in which severe and dangerous symptoms supervened. Palm, in his collected statistics of 25 cases, recorded 18 deaths—three from collapse, six from acute peritonitis, three from chronic peritonitis, and six from protracted fever. Nepben, in 155 cases, showed 65 to have terminated fatally. In these instances the contents of the cysts must have been intensely irritating and in many cases probably they were septic; in a certain proportion death was accounted for by hæmorrhage. The causes of rupture were numerous, such as violence, morbid processes in the cyst wall, the result of thrombi, and intra-cystic hæmorrhage. Nutritive disturbances of the wall, the result of torsion of the pedicle, were a further frequent cause. Perhaps the commonest variety of cyst to rupture spontaneously was that with gelatinous contents, the cyst wall becoming secondarily softened. The gelatinous contents were, as a rule, more irritative, but at the same time they were but slowly absorbable by the peritoneum and might continue to distend the abdomen. These were more often found to be ruptured on opening the abdomen, as when the contents of the cyst were more fluid they were readily absorbed. In the latter case the cyst might become permanently obliterated. This occurred most frequently in unilocular broad ligament cysts, where the fluid was practically normal saline solution and was extremely rapidly absorbed, giving rise to temporary polyuria. In other cases the tumour re-distended or secondary cysts took on active growth. This seemed to be of comparatively frequent occurrence, as cicatrices were often present in the cyst walls of tumours. The contents of the cyst, though absorbable, might be irritative and might cause peritonitis with adhesions so widespread as to prove an almost insuperable barrier to its removal. Previous tapping of the tumour resulted in a similar condition. In a certain group of cases, practically lacerated cysts with gelatinous contents, no absorption took place; the opening remained patent and active secretion continued. The abdomen steadily distended with intra-peritoneal fluid. The treatment of ruptured cysts consisted in removal of the cysts as soon as possible. A certain proportion of cases after rupture seemed never to re-distend and a spontaneous cure resulted, but as delay might allow strong and widespread adhesions to form early operation was advisable. On operating in such a case, the surgeon was apt in entering the peritoneal cavity to be misled by the gush of ovarian contents and to assume that the cyst wall had been incised. An attempt would then be made to separate the cyst wall from suspected adhesion to the abdominal parietes. This resulted in stripping off the parietal peritoneum. In these cases it was well to enlarge the opening and to introduce the hand into the cavity before attempting the separation of the cyst wall. In cases with acute symptoms the diagnosis might be extremely doubtful unless there was a distinct history of a pre-existing abdominal tumour. The symptoms might be simulated by perforation of the intestine or other acute peritoneal affections. The operation could then at first be only exploratory.—Professor A. R. SIMPSON remarked that in almost all cases where the tumour disappeared it was par-ovarian in character. The most interesting were the cysts with gelatinous contents, where this material, spreading over the peritoneum and adhering to the different viscera, might become vascularised. These cases had a serious prognosis. In all ruptured cysts recrudescence almost always occurred. In some cases after rupture of the cyst peptones had been found in the urine.—Dr. D. BERRY HART, Dr. J. FOULIS, and Dr. HAIG FERGUSON also discussed the paper.

Dr. BERRY HART read a paper on Uterine Retraction with special reference to the Mechanism and Management of the Third Stage of Labour. He pointed out the discrepancies between the usual views as to the mechanism of the separation of the placenta during the third stage and the practice adopted in the management of this stage. He defined retraction as muscular action (contraction) where a part of the thickening of the muscle was retained after the contraction proper had ceased. In sections of the parturient uterus it was remarkable that the uterine wall at the placental site was thinner than elsewhere. The uterus removed by Porro's operation showed a uniformly retracted and thick wall, while uteri with the placenta still attached, obtained by post-mortem examination and thus intact uteri, had a thin wall on section at the placental site, thinner than the uterine wall elsewhere above the retraction ring. He believed that the state of the uterus after Porro's operation could not be accepted as evidence of the amount of retraction in a normal third stage, but was an over-retracted uterus owing to the longitudinal and transverse incisions necessary in the operation. Dr. Hart next drew attention to the elastic recoil of the uterus following a pain and pointed out the importance of the elastic tissue in bringing this about. He finally emphasised the great importance of the fact that the placenta was separated during the third stage by a disproportion between the placental area and the placental site, and that it followed from this that as the disproportion occurred in the elastic recoil (that is, after the pain was over) the Crédé method was a source of danger if practised during the early period of this stage before the placenta was separated.—Dr. HAULTAIN, Dr. JAMES RITCHIE, Dr. FOULIS, Dr. BALLANTYNE, Dr W. FORDYCE, Dr. H. O. NICHOLSON, and Dr. MILNE MURRAY joined in the discussion of the paper.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Delivery by Cæsarean Section and afterwards by Forceps.—Placenta Prævia.—Epithelioma of the Cervix Uteri.

A MEETING of this section was held on Dec. 21st, 1900, Dr. A. V. MACAN, the President, being in the chair.

Dr. F. W. KIDD read notes of a case of Application of Forceps where Cæsarean Section had previously been performed. —Dr. R. D. PUREFOY said that one of the many interesting points raised by that important case was the light which it helped to throw upon the behaviour of fibroids in cases in which the patient became pregnant.—Dr. SMITH said that he recollected a pregnant woman who came to him with a large tumour occupying the pelvis. On examining her under ether he could not push the tumour out of the pelvis and he thought that the woman could never deliver herself; but in fact she did deliver herself without any difficulty.—Dr. MACAN said that he thought they should either suppose some great change had taken place or else that in the second labour, for some reason, the tumour had been drawn upwards out of the pelvis.

Dr. R. L. HEARD described a case of Placenta Prævia. The patient was 31 years of age, was in her fifth pregnancy, and was admitted into the Rathdown Infirmary on Nov. 3rd, being then collapsed and suffering from acute septicæmia. Hæmorrhage had commenced 14 days previously. The fœtal heart-sounds being absent the child was considered to be dead. Dr. Heard found the whole vagina in a state of great œdema. It was with difficulty that he could reach the os with his finger, and when he did so he was unable to ascertain anything definite, beyond feeling the placenta, the os being of the size of a shilling. Ether was administered, and the cervix was dilated with a Barnes's bag. He then separated the placenta with his finger round the lower zone. It had a central insertion and was beginning to decompose. Going through it he found that the breech was presenting, the child being in the right dorso-anterior position; he then delivered by bringing down the legs. The fœtus was very slightly macerated. The placenta came away during the delivery of the body. The uterus was washed out with creolin solution and one-hundredth of a grain of citrate of ergotin was given hypodermically. Shortly after Dr. Heard had left the patient she succumbed to a syncopal attack, in spite of hypodermic injections of strychnine and ether by Dr. Pim, the application of amyl nitrite to the nostrils, a boiling hot sponge to the cardiac region, artificial respiration, and partial inversion. One of the chief points of interest in the case was, Dr. Heard thought, the œdema of the vagina. He had never seen an instance of the kind before.

The Secretary read a paper by Dr. R. J. KINKEAD on Epithelioma of the Cervix Uteri during Pregnancy.—Dr. MACAN said that he thought it was the first case of the kind which had been performed in Ireland—viz., primary removal of the carcinoma and the hysterectomy after labour. Dr. Kinkead deserved the greatest credit for having brought it to a successful termination.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.—A meeting of this society was held on Jan. 10th, Mr. J. Rutherford Morison, the President, being in the chair. —Dr. I. G. Modlin described a case of Partial Paralysis of the Right Arm occurring in a man, aged 54 years, who dislocated his right shoulder three months ago. The dislocation was reduced under chloroform by means of the heel in the axilla. Three weeks after the accident the patient consulted a local bonesetter who kept the arm bandaged for three weeks. There were now impairment of sensation, almost complete paralysis, and marked muscular wasting, especially in the distribution of the ulnar, musculo-spiral and median nerves, indicating injury to all the cords of the brachial plexus, caused more probably by the pressure of the dislocated head of the humerus than by the method of reduction.—Some discussion followed during which it was pointed out that such cases were not uncommon. The patients usually recovered completely, but they should be warned that complete recovery would be slow, taking probably from one and a half to two years.—Dr. Modlin also described a case of Focal Epilepsy occurring in a man, aged 37 years, who gave an indefinite history of injury while drunk; he worked two days later and on the third day became delirious and exhibited pyrexia and stupor; on the fifth day he had his first fit. The fits recurred every five minutes and later every two minutes, commencing in the left side of the face, rapidly extending to the left arm and leg and subsequently becoming diffuse. A slight contusion was evident over the right parietal eminence. The patient was trephined over the right Rolandic area. The membranes bulged but did not pulsate. The dura mater was incised and a large clot was found extending as far as could be felt; as much of the clot was removed as possible, the patient having two slight fits afterwards and from this point making a complete and uninterrupted recovery.—Dr. Modlin also described a case of Ovarian Cyst complicating Pregnancy at full term. The patient was 21 years of age and when first seen, three weeks from term, was suffering from incontinence of urine and such extreme enlargement of the abdomen as to render her unable to move out of bed or to turn over. The abdomen, hugely distended, was dull on percussion up to the ensiform cartilage and was resonant in the extreme flanks, fluctuation being readily elicited. Per vaginam the uterus appeared to be pushed to the left by a large cystic tumour; through the dilated os the fœtal head could be felt. It was decided to wait and in due time, pains having commenced, delivery was expedited by forceps under anæsthesia. Eight days later, the abdomen having been rapidly increasing in size and the temperature having risen to 102° F., laparotomy was performed and a large suppurating ovarian cyst was removed by the usual method. Recovery was complete in a fortnight.—Dr. R. A. Bolam showed a case of Acromegaly occurring in a man, aged 35 years, who presented the typical enlargement of features and extremities usual in this condition. He complained of extreme headache and prostration. Although the optic discs exhibited no pallor his perimetric chart showed a decided contraction of the field of vision.—Dr. H. B. Angus described a case of Hæmatemesis from Gastric Ulcer treated by Surgical Ligature. A girl, aged 22 years, was admitted into hospital in a condition of extreme collapse from hæmatemesis which was still continuing. Having had previous experience of two cases of fatal hæmorrhage from gastric ulcer in which post-mortem examination had revealed the bleeding point to have been from a large vessel impossible of treatment by medical means he had determined upon gastrotomy and ligature in this case. The method which he had adopted was the passage of a purse-string suture around the ulcer. From the operation the patient had recovered, having no further hæmorrhage, but 10 days later she developed thrombosis and phlebitis of both femoral veins; this condition he ascribed to her extremely weak state, being unable to trace any association between it and the operation.—Dr. A. M. Martin brought forward six patients who had been operated on for the removal of Loose Semilunar Cartilage, the periods since operation varying from six months to three weeks. In all of them the cartilage at fault had been the internal. All the patients were miners, whose work, entailing flexion of the knee and rotatory movement, rendered them peculiarly liable to the accident. In five of the cases the cartilage was completely detached circumferentially, the extremities remaining fixed; in one case a portion of the inner rim was partially separated. The portion of cartilage detached was in all cases removed. The patients now exhibited perfect and useful joints and were rid of their distressing symptoms. — Dr. James Drummond read a paper on the Essentials in the Management of a Normal Case of Labour. After defining normal labour he discussed the subject under the following headings: the incidence of puerperal sepsis; occasional auto-infection; other sources of infection; the value of surgically cleansing the patient, the attendants, and the instruments; and the avoidance of frequent examinations, of ante-partum douching unless specially indicated, and of hasty instrumentation.—An interesting discussion followed in which Dr. Calthrop, Dr. Adamson, Dr. S. S. Whillis, Dr. Davis, Dr. Modlin, and Dr. J. W. Smith took part.—Dr. H. P. Bennett and Dr. A. S. Percival exhibited specimens o Glioma and Pseudo-glioma of the Retina. — Dr. Beattie exhibited (1) a Multiform Aneurysm of the Descending Thoracic Aorta containing a laminated clot of the size of a cocoa-nut; and (2) a Small Sacculated Aneurysm springing from the posterior surface of the transverse arch which had burst into the trachea.

ULSTER MEDICAL SOCIETY.—A meeting of this society was held on Jan. 10th, Professor W. H. Thompson, the President, being in the chair.—Dr. W. Calwell showed a young man with marked Unilateral Contraction of the Chest due to Fibrosis of the Lung.—Dr. A. Fullerton showed a child from which he had removed a Congenital Sacculated Cyst of the Neck which contained blood and which subsequent examination proved to be a form of dilated lymphatics or lymphangiectasis.—Dr. John McCaw exhibited an infant who had been successfully treated by antitetanic serum for Tetanus Neonatorum.—The following specimens were shown: Dr. J. S. Darling (Lurgan): 1. Recent Extracapsular Fracture of the Femur. 2. Sarcoma of the Root of the Lung which during life simulated an aneurysm. It was a round-celled sarcoma and originating in the glands took the form of pigmented gland tissue. 3. Aneurysm of the Right Corner of the Arch of the Aorta which ruptured externally. It was taken from a soldier who had a specific history and suddenly ruptured externally one night after a bout of drinking. 4. Aneurysm of the Descending Aorta which caused death by rupturing into a bronchus. It was taken from the body of an old woman who died suddenly after coughing up a quantity of blood and in whom the cause of death was obscure, but was shown to depend on an atheromatous ulcer of the aorta protruding into the lung.—Dr. Calwell: 1. Aneurysm of the Arch of the Aorta which ruptured into the posterior mediastinum. 2. A Stomach with a small Gastric Ulcer which caused death by severe hæmorrhage.—Dr. A. B. Mitchell: Tuberculous Testicle.—Dr. S. English: Anencephalic Fœtus.—Dr. J. Lorrain Smith demonstrated the pathological features of many of the specimens exhibited.—Dr. Mitchell showed radiograms of (1) a Coin in the Œsophagus of a Child; (2) Fractured Olecranon; and (3) a rare Fracture of the Foot.—Dr. McCaw read notes of a case of Tetanus Neonatorum successfully treated with antitetanic serum. The child was brought to the Belfast Hospital for Sick Children 14 days after birth with well-marked signs of infantile tetanus and with the history that for a few days previously it had been refusing the breast from inability to suck. The umbilical scar was in a very unhealthy sloughing condition. Dr. McCaw immediately injected five cubic centimetres of antitetanic serum and two days afterwards gave a second dose of two and a half cubic centimetres of the serum. The child recovered. Dr. Lorrain Smith cultivated the tetanus bacillus from swabs of the umbilicus and specimens of the "drum-stick" organism were shown at the meeting.—In the discussion following the reading of the paper Dr. Lorrain Smith drew attention to the fact that to be effective in causing tetanus the "drum-stick bacillus" seemed to require to be associated with some other pus-producing organism. It appeared that pure cultures of the tetanus bacillus, when injected into animals, did not cause, as a rule, any of the classical symptoms of the disease but did so if pus-producing organisms were injected with them. Being anaerobic it might be that the tetanus bacillus only acted when the other associated organisms had used up the oxygen.—Professor Byers said that Dr. Lorrain Smith's most interesting observations in reference to the life-history of the tetanus bacillus explained the fact that in pre-antiseptic days cases of the disease were common among the infants born in lying-in hospitals, while now, owing to proper aseptic precautions, both in the management of the mother and of the umbilicus of the child, the pus organisms had been eliminated probably as well as the tetanus bacteria; but even if the "drum-stick" bacilli got into the umbilical wound the prevention of any form of suppuration rendered its presence innocuous. He referred to the scourge of St. Kilda (tetanus neonatorum) and explained how it had been stamped out by proper antiseptic care of the umbilical cord. In reference to the employment of serums he said they could only judge scientifically of their effect when the organisms against which they were used were isolated and cultivated from the persons infected. In the case of puerperal fever where there was often multiple infection it was most unscientific to claim results for the anti-streptococcic serum until bacteriological examination of the lochia established first the prevailing type of organism present.—Dr. Henry O'Neill read a paper on Meat Inspection in which he drew special attention to the importance of the medical profession educating the public to use no meat which did not bear an official stamp that it had been duly inspected and passed as sound and non-tuberculous. Dr. O'Neill said that in both Dublin and London the butchers had been too formidable for the corporations to carry out meat inspection as thoroughly as it was done in Paris, Leipsic, and Berlin; but that in Belfast the law compelling meat inspection had been passed by the city corporation and was only awaiting the tardy action of the Local Government Board to make it legal.—Dr. R. W. Leslie read notes of a case of Hæmothorax occurring in a boy, aged 14 years, following a wound in the side caused by a pen-knife. After two tappings, on each of which blood was drawn off, the patient recovered with full expansion of the affected side.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 10th, when Dr. A. Whitfield showed a Mother and Child affected with Syphilis. In both cases the disease was acquired. The child was aged six years and had been seen with a generalised early eruption of syphilis at the age of five years. The mother had been treated for recent syphilis two years before, that was when the child was four years of age. At the time of exhibition the mother showed a symmetrical eruption of very perfect rings about one inch in diameter, situated on the flexor surfaces of the forearms. The rings were of a very superficial character and of a florid pink colour, so that without the previous knowledge of the patient the diagnosis would have presented considerable difficulties. The child had been shown to the society one year before with a marked eruption on the back. She had been rendered at one time very dangerously ill by her mother's having disobeyed orders. Owing to the fact that grey powder had disagreed with the stomach she had been ordered mercurial inunction, but the mother had supplemented this by giving her some of her own mercurial medicine. The result was a severe mercurial stomatitis with considerable ulceration of the mouth. The child might now be said to be on the road to recovery, but she still showed ulcerative syphilitic lesions belonging to the deep ecthymatous type.—Mr. Mower White showed a patient, aged 39 years, whose illness began with sudden severe abdominal pain while she was lifting a coal-scuttle, and on the following day she was admitted into hospital suffering from acute peritonitis. She was three months pregnant. The abdomen was opened in the middle line and a large quantity of thin pus escaped; in the lower part of the abdomen the peritonitis was general, and plastic lymph coated many of the coils of the small intestine; the pelvic organs were normal; the peritoneum in the neighbourhood of the vermiform appendix, which lay in a subcæcal fossa, was very acutely inflamed; the appendix was therefore removed, although it showed no gross lesions externally. Subsequently, a perforation of the small intestine covered by the lower extremity of the great omentum was found; the perforation, which appeared to be in the lower part of the ileum, was placed on the unattached side of the bowel; it measured one-third of an inch across; the sides of the opening measured half an inch, so great was the inflammatory thickening of the intestinal coats around the aperture. The patient's condition seemed to preclude enterectomy. To close the aperture three sutures were passed right across the ulcer, serving to bring its sides fairly closely together; then the omentum, first carefully cleansed, was wrapped round the intestine so as to cover four or five inches of it and was sutured to both aspects of the mesentery and also to the surface of the bowel. During the operation some gallons of hot salt solution were used to irrigate the peritoneal cavity and as far as possible the lymph was stripped off the peritoneum. A large rubber drainage-tube was left in the pelvis. The patient made a good recovery. She aborted on the seventh day after the operation; the temperature was normal on the twelfth day and the drainage-tube was finally removed on the fourteenth day. From the seventeenth to the thirtieth days there was fever (maximum temperature 103° F.) without apparent cause. The bowels were constipated throughout the illness. Mr. Mower White suggested that the case was one of typhoid fever in which perforation had occurred, though he had not during the operation observed any evidence of further ulceration of the ileum. Possibly, however, the febrile period interrupting convalescence represented one of the common relapses of this disease.—Dr. Emslie Smith showed for Mr. Ewen Stabb: (1) A case of Myoma Uteri; and (2) a case of Tumour of uncertain nature in connexion with the Right Kidney.

CHELSEA CLINICAL SOCIETY.—A meeting of this society was held on Jan. 15th, Dr. William Ewart, the President, being in the chair.—Mr. C. A. Morris read a paper

on Tubal Pregnancy, with notes on two cases of this condition upon which he had operated. Attention was called to the many and generally uncommon diseases which were at one time considered as the cause of pelvic hæmatocele, whilst at the present time tubal pregnancy was looked upon as the condition which in the majority of cases produced it. The cases read showed two of the terminations of tubal pregnancy; in one an early gestation sac ruptured into the peritoneum and abdominal section was performed while hæmorrhage was proceeding. The fœtation was removed with its adjacent tube and ligament In the second case a tubal pregnancy had ruptured extra-peritoneally between the layers of the broad ligament, and as it continued to distend this and to cause pressure symptoms abdominal section was performed. The tumour of the tube was removed, but the distended broad ligament was left untouched. Both operations were successful and the patients were now in good health. The structure and mode of formation of a tubal mole were touched upon and several specimens of this morbid condition and of tubal pregnancy were shown.—A discussion followed, in which the President, Dr. Vincent Dickinson, Dr. C. J. Harrison, and Mr. D. Vinrace took part.—Dr. J. Blumfeld read a paper on the After-effects of Anæsthetics. After alluding to the preparation of patients for the taking of anæsthetics generally and to the best treatment of them during the hours immediately following operation, Dr. Blumfeld described more specifically the after-effects usually experienced from the various commonly used anæsthetic agents. He related cases which were of interest from the more unusual nature of the after-effects, and he divided these effects, broadly speaking, as they affected (1) the central nervous system; (2) the viscera generally; and (3) the circulatory system. Cases of paralysis of peripheral and central origin were discussed and the relationship of insanity and epilepsy to the conditions of general anæsthesia. Dr. Blumfeld concluded by laying stress upon the extent to which after-effects might be avoided or diminished by proper attention to the selection and administration of anæsthetics and the proper preparation and after-treatment of the patient.—A discussion followed in which the President, Dr. J. J. Marsh, Dr. C. C. Gibbes, Dr. C. J. Harrison, Dr. Vincent Dickinson, Mr. D. Dallaway, Mr. J. D. Mortimer, Mr. Foster Palmer, Mr. R. L. Norman, and Mr. Vinrace took part.

PATHOLOGICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on Jan. 16th, Dr. A. T. Wilkinson, the President, being in the chair.—Dr. W. E. Fothergill showed Microscopic Sections of a Growth which in appearance and in clinical history corresponded to the accepted descriptions of the so-called deciduoma malignum. He also exhibited sections of hydatid mole, of decidual tissue, and of the chorionic structures from which, according to different authorities, the growth in question was derived.—Professor G. A. Wright showed a specimen of Simple Hypertrophy of the Breast removed from a girl, aged 12 years. Both breasts were affected. The gland removed weighed about 8 lb.—Dr. T. A. Goodfellow and Professor Wright showed a specimen of Arteritis, probably gouty. Thrombosis of the popliteal artery led to gangrene of the foot and the limb was removed above the knee. Recovery followed. The patient, a man, aged 52 years, had previously suffered from phlebitis of the veins of the leg with resulting embolic pneumonia.—Mr. J. E. Platt showed a specimen of Trichinosis of the Triceps Muscle. The trichinosis had been discovered during the course of an operation for a supposed sarcoma of the muscle. The patient was a man, aged 61 years, a labourer by occupation, and the trichinosis in all probability had originated three years previously, at which time he had suffered from an illness supposed to be influenza. A tumour in the triceps muscle had been first noticed three months before he came under observation and had attained the size of a tangerine orange. After removal the tumour was found to be probably of an inflammatory nature, but its true relation to the trichinosis could not be definitely stated. The man had made an uninterrupted recovery. Some remarks were made on the previous occurrence of trichinosis in this country.—Dr. Arnold W. W. Lea showed a series of Uteri and Appendages removed by the "vaginal radical operation."

SOUTHPORT MEDICAL SOCIETY.—A meeting of this society was held on Jan. 9th, Dr. R. Harris being in the chair. Three new members were elected.—The chairman briefly reported the result of the recent interview with the coroner on the subject of medical evidence at inquests. The coroner had declared himself entirely in the hands of the county council in the matter and advised a direct approach to the council.—After some discussion the question was left in the hands of a sub-committee for further consideration and report.—Dr. W. H. Barrett read notes of an Unusual Case of Interstitial Nephritis complicated by the presence of a sarcoma. (The specimen was shown.)—Mr. Charles G. Lee (Liverpool) read an interesting paper entitled, "Four Cases from a Specialists' Note Book." Particulars of two cases of acute glaucoma and two cases of cerebral suppuration following suppurative otitis media were given and the practical lessons deduced.

MANCHESTER MEDICAL SOCIETY.—At the annual meeting of this society held at Owens College on Jan. 16th the following gentlemen were elected office-bearers for the ensuing year:—President: Mr. A. H. Young. Vice-Presidents: Dr. A. Donald, Dr. J. Mackenzie, Dr. W. Milligan, and Mr. A. Wilson. Honorary treasurer: Mr. J. W. Smith. Honorary secretary: Dr. E. S. Reynolds. Committee: Mr. W. Coates, Mr. J. Collier, Dr. J. J. Cox, Dr. T. Harris, Dr. M. P. Ledward, Mr. W. P. Montgomery, Dr. F. C. Moore, Mr. J. H. Ray, Dr. C. G. L. Skinner, Dr. W. K. Walls, Dr. R. B. Wild, and Dr. R. T. Williamson. Library Committee: Dr. T. N. Kelynack, Dr. A. W. W. Lea, and Mr. J. E. Platt. Auditors: Dr. F. J. H. Coutts and Dr. Edgar Helme.

Reviews and Notices of Books.

Cancer of the Uterus: its Pathology, Symptomatology, Diagnosis, and Treatment. By THOMAS STEPHEN CULLEN, M.B. Toronto. With 11 Lithographic Plates and also 300 Coloured and Black Illustrations in the Text. London: Henry Kimpton. 1900. Pp. 693. 8vo. Price 31*s.* 6*d.* net.

THIS book of Dr. Cullen's is further proof, if indeed proof were wanted, of the exceedingly good work which is being done by numerous observers at the Johns Hopkins University. It is a monograph on cancer of the uterus of great value and is a lesson as to the right method of dealing with the abundant material of this kind which must be met with in every large hospital. The work is founded upon the examination of 182 cases of cancer of the uterus. Of these, 128 were squamous-celled carcinoma of the cervix; 19 adeno-carcinoma of the cervix; and 35 adeno-carcinoma of the body of the uterus. A full and good account is given of the normal anatomy and histology of the uterus, illustrated by numerous figures, many of which are taken from Kelly's "Operative Gynæcology." The chapter upon the Removal and Examination of Uterine Tumours for Diagnosis illustrates how completely and methodically Dr. Cullen has examined his material and enables us to form an opinion as to the value of his results. In describing the appearances and structure of squamous-celled carcinoma the author states that this variety of cancer of the cervix consists of an ingrowth and branching of the squamous epithelium of the part, and coincident with the ingrowth there is generally a branching outgrowth of the stroma and epithelium, forming a cauliflower or mushroom-like growth. As to whether the stroma is a malignant growth or only due to irritation the author leaves undecided. The account of all the varieties of cancer is illustrated by numerous cases very fully recorded, both as regards their history, clinical features, and the result of macroscopic and microscopic examination. It may be objected that this greatly and unnecessarily increases the size of the book. It is, however, not a work mainly intended for students, and in a matter of this kind what the experienced reader wants are facts upon which he can come to his own conclusions, apart from the deductions drawn from them by the author. As to the quality and the quantity of the facts in this book there can be no complaints. Dr. Cullen points out that macroscopically the

cauliflower-like growth is really made up of papillary masses consisting of finger-like outgrowths. A very interesting chapter is that upon the extension of squamous carcinoma of the cervix. The author agrees with Winter that the lymph-glands are usually involved late in the disease, and in answer to the question as to why this is so he suggests that the epithelial cells are too large to enter the lymph radicals. The growth must therefore extend out into the broad ligament and break into a large lymph channel before the cells can reach a lymph gland. It is stated in the preface that the reader will be surprised at the small amount of space devoted to symptomatology, but the results of his researches lead Dr. Cullen to the conclusion that diagnostic symptoms at best are meagre and in the early stages give little or no clue to the real nature of the disease. Hence the value of curettage when there is the slightest uterine hæmorrhage that cannot be explained. The first symptom in the great majority of cases of squamous-celled carcinoma is usually a bloody discharge. In the chapter upon the Diagnosis of the Variety of Cancer of the Uterus all the various conditions likely to be confounded with malignant disease are given in detail, and this is also done in the corresponding sections devoted to the differential diagnosis of adeno-carcinoma of the cervix and adeno-carcinoma of the body of the uterus.

In the treatment of squamous-celled carcinoma it is said of abdominal hysterectomy: "this operation should be preferred in all cases where the patient is not too stout," and the method described by Werder is advocated. These extensive operations are at the present time practised by many of the American school of gynæcologists. They have, however, not yet been done in sufficient numbers to enable us to judge whether they are likely to increase the chance of complete cure or not. We must remember that the analogy so often drawn between cancer of the uterus and cancer of the breast does not in reality hold good. Werder's operation of abdominal hysterectomy is undoubtedly a very ingenious method of avoiding fouling of the peritoneal cavity with the carcinomatous growth, and he deserves great credit for it. Whether it will ever take any permanent place in the art of surgery remains to be seen. Even when the ureters are catheterised the danger of including one in the ligature is great, and in these cases catheterisation of both is often impossible. The description of vaginal hysterectomy is practically the same as that in Kelly's Gynæcology. A warning is given against the fallacious advice that even when the disease is too advanced for complete removal hysterectomy should still be done so as to give the patient relief. Many of such patients obtain no relief at all and run the risks of the operation without any resulting benefit. In adeno-carcinoma of the cervix stress is laid upon the changes in the epithelium. Dr. Cullen says that the cells differ greatly from those of the normal cervical epithelium and cannot morphologically be recognised as derivatives from it. He also finds that, at any rate in the early stages of both squamous carcinoma and adeno-carcinoma of the cervix, no changes are to be found in the body of the uterus. One interesting fact is brought out, and that is that all forms of cancer are equally common in the white and black races, contrary to the idea which at one time prevailed that cancer was rare in the negress. The extreme importance of the examination of scrapings in the diagnosis of early adeno-carcinoma of the body of the uterus cannot be too much insisted upon, and what striking results may be obtained by the examination of such scrapings by a competent pathologist is shown by many of the cases recorded. A very good example is figured on page 363. Dr. Cullen is inclined to believe that the papillary form of cancer of the body of the uterus has probably started in the surface epithelium and that when a gland-like arrangement is met with that it has taken origin in the glands themselves. The clear statement of the author as to whether a fibro-myoma of the uterus can undergo carcinomatous degeneration is to be welcomed. He has failed to find a single instance amongst his cases of adeno-myoma becoming malignant, and, as he says, to speak of carcinomatous degeneration of a myoma is a contradiction in terms. The very late stage of cancer of the body at which the glands become involved is a similar condition to that obtaining in cancer of the cervix. In nearly all the operable cases of adeno-carcinoma of the body met with no glandular involvement had taken place, and this accords with the experience of Winter. In four out of 500 cases of myomata carcinoma of the body has been present as well. In connexion with the diagnosis of cancer of the body of the uterus a clear account is given of the changes in the mucous membrane in cases of endometritis and similar conditions. In all cases of carcinoma of the uterus it is recommended that the tubes and ovaries should be removed as well, since in some of the cases, although in the early stage, the appendages were already involved. In a critical review of the rare cases of so-called squamous carcinoma of the body of the uterus it is noted that in only nine of 50 cases of endometritis was there any thickening of the epithelium resembling squamous epithelium. Of the recorded cases of squamous carcinoma of the body Dr. Cullen is only inclined to admit three—viz., those of Gebhard, Kaufmann, and Flaischler. The account of deciduoma malignum is mainly taken from Whitridge Williams's and Dorland's monographs on the subject, a detailed description being given of Whitridge Williams's case. Dr. Cullen is in favour of retaining the name "deciduoma malignum," and is of opinion that the clinical features are sufficient to distinguish it from sarcoma and carcinoma of the uterus. In cases of pregnancy complicated by inoperable cancer of the uterus Cæsarean section followed by Porro's operation is recommended; in operable cases vaginal hysterectomy or vaginal Cæsarean section. One of the most interesting chapters is that upon the clinical phenomena common to carcinomata of the uterus. The results of the operative treatment in the Johns Hopkins Hospital are given in detail. In only one case did recurrence occur other than locally. This patient remained well for more than a year and then suddenly the inguinal, axillary, and cervical glands became enlarged and she died 20 months after operation.

Of 61 patients operated upon for squamous-celled carcinoma of the cervix 13 were still alive in January, 1900, the period of time that had elapsed since operation varying from 10 months to six years and two months. In four cases more than three years had elapsed. The uterus was removed in six cases per vaginam, in five by the abdominal route, and in the remaining two combined vaginal and abdominal hysterectomy was performed. In 12 cases of hysterectomy for adeno-carcinoma of the uterus only two (16 per cent.) of the patients were known to be living—one five years and seven months after the operation, the other five years and three months. Of 30 cases of adeno-carcinoma of the body of the uterus 20, or 66 per cent., were still free from recurrence. Of these the period since operation varied from 11 months to six years. In 12 instances the patients had remained free from recurrence for more than three years.

In summing up the various analyses as to the causation of carcinoma, Dr. Cullen finds that heredity appears to have little influence, that trauma as produced by parturition has a causal relation to cancer of the cervix but not to that of the body, and that the weight of evidence is against the parasitic theory.

The numerous illustrations in the book are beautifully drawn and reproduced, and the whole work reflects the greatest credit upon all concerned in its production.

Elements of Human Physiology. By ERNEST H. STARLING, M.D.Lond., F.R.S., Jodrell Professor of Physiology, University College, London. Fourth edition, 8vo. London: J. & A. Churchill. 1900. Pp. 679. Price 12*s*. 6*d*.

WE are glad to welcome Professor Starling's well-known manual in a more imposing form. Like other treatises that have originally appeared in an unpretending fashion and have been found well adapted to the needs of the student it is undergoing a process of evolution that will, we fear, end in its being only serviceable to the teacher when it will be replaced by some more elementary work. As it stands, however, we can only speak of it as one of the best of the numerous handbooks of physiology that have recently appeared. It is written by one who has not only a very thorough knowledge of the literature of his subject but by one who has had large experience of practical and experimental physiology and who has written many original articles that have commanded attention. Professor Starling gives straightforward statements explanatory of each of the separate great functions of the body, illustrating them where illustrations are required for the comprehension of the text by diagrammatic sketches. Some of these are too coarse and hence misleading, as those, for example, of the blood corpuscles. He has avoided notes which only serve to distract the attention of the reader, especially if he be an inexperienced one, and he has introduced the names of authorities sparingly.

The first chapter, devoted to the Material Basis and the Sources of Energy of the Body, shows that 12 chemical elements enter into the composition of all living organisms. The names of these 12 are carbon, hydrogen, nitrogen, oxygen, sulphur, phosphorus, chlorine, potassium, sodium, calcium, magnesium, and iron. Four others are occasionally present—silicon, iodine, fluorine, and manganese. These are all found on the crust of the earth, and for the most part in a state of maximum oxidation and are devoid of potential energy. Plants, under the influence of the sun's rays, build up these elements into substances which can develop energy by combustion. The green parts of plants utilise the radiant energy of certain parts of the spectrum in the splitting up of CO_2, giving off the oxygen to the atmosphere and building up the carbon into complex compounds of which the earliest appear to be sugar and starch. "It is supposed," he continues, "that the first change which occurs is a formation of formaldehyde $CO_2 + H_2O = CH_2O + O_2$, and that this formaldehyde by simple condensation yields a carbohydrate of the formula $C_6H_{12}O_6$. The plant thus obtains a store of potential energy which it can utilise for the formation of still higher products or for the synthesis of such bodies as fats and proteids. All three classes of substances, proteids, fats, and carbohydrates, are built up together with salts and water to form the unstable material which as the chemical basis of life is known as protoplasm." The relations of animals to plants are then discussed and some of the numerous synthetic processes which they can effect are given. The remainder of this important chapter describes the theoretical mode of formation, the properties and the chemical characters of the proteids, fats, and carbohydrates. The chapters on the contractile and nervous tissues are highly instructive and embody the results of much research.

Napoleon is said to have maintained that a history of France must either be compressed into a single volume or expanded into 20. The same may be said of a history of physiology; the number of articles that have been written on almost every part of it, the number of experiments that have been made, often with contradictory results, is so enormous that one of two modes of treatment must be adopted: either the facts must be given with discrimination *in extenso*, as is done in such works as Hermann's, Richet's, or Schäfer's physiological treatises, or a succinct account must be attempted in which the impressions of one writer are set down in a dogmatic manner, and the student must accept the statements made without any clear comprehension of the grounds on which they rest. There can be no question of the relative interest attached to the perusal of works written on these different lines, especially in dealing with such a subject as physiology. If short, a book covering the whole field of physiology must be dry; if extended, it may be made highly interesting. As might be expected, Professor Starling everywhere gives the established facts in physiology in a very clear and logical fashion, and while it would appear in parts that he writes rather for the young physiologist than for the student of medicine, yet it must be remembered that a true study of physiology involves an accurate knowledge of organic chemistry.

A Manual of Modern Surgery: an Exposition of the Accepted Doctrines and Approved Operative Procedures of the Present Time for the Use of Students and Practitioners. By JOHN B. ROBERTS, A.M., M.D., Professor of Anatomy and Surgery in the Philadelphia Polyclinic; Mütter Lecturer on Surgical Pathology of the College of Physicians of Philadelphia. Second Edition. London: Rebman, Limited. Pp. 850. Illustrated with 473 Engravings and eight Plates in Colour and Monotone. Price 21*s*.

THIS is the second edition of the above work, but as its title-page contains no date we are left in doubt as to when it was issued. The author tells us in his preface that many articles have been entirely rewritten and that the text throughout has been thoroughly revised, and therefore we are justified in thinking that it is intended to represent the views of the present day.

There is much to praise in the general arrangement of the volume and the descriptions are for the most part clear and concise, but we cannot help thinking that there is in many cases a lack of appreciation of the relative importance of the subjects dealt with. For instance, the account of a bunion and the description of lithotrity occupy approximately the same space—less than a page and a half each. There is also observable a tendency to indefiniteness of statement, for the author frequently employs the expressions "it is said" and "it is stated" without any indication as to his agreement or disagreement with these opinions, and when this occurs in the descriptions of treatment the student is at a loss to know what to think. What a student requires in a text-book is a clear indication of the best treatment, and a certain degree of dogmatism is not only justifiable but distinctly advisable. Regarded as a whole the book may be considered to be a very trustworthy guide to the student or practitioner, and there are really but few statements to which we could take exception. It is certainly a mistake, however, to speak of congenital syphilis as the "quaternary" stage of the disease, for the congenital variety of the disease in the child cannot be a "stage" of disease in the parent but is a distinct attack of the disease. Especially objectionable is this application of the name "quaternary" because it has already been applied to very late manifestations of the syphilitic poisons, such as locomotor ataxia and general paralysis of the insane. In the description of Colles's fracture of the radius the author says: "It is frequently designated by the name of one or other of those writers who have discussed it, but such nomenclature serves to confuse the student and to perpetuate erroneous teaching." We certainly fail to see how this applies to the use of Colles's name for this fracture, and we cannot perceive that the student is less likely to be confused by the use of the names "ordinary" or "classic" fracture which the author applies to it. Personal names frequently assist the memory in a remarkable degree, and where a particular condition has been associated for many years with a personal

name it is wise even in the interests of students to retain it. The use of proper names to designate diseases and signs and symptoms of diseases has been overdone, and no new appellatives of this kind should find their way into our scientific vocabulary, but perfectly well-established terms must be retained.

We agree with the author that the terms "intra-capsular" and "extra-capsular" as applied to fractures of the neck of the femur are not well chosen, but he does not appear to perceive that however they may be named there are two definite varieties of fracture of the femoral neck which differ in the mode of origin, in the treatment, and in the results. On page 536 is an illustration of a sling in which the hand is shown in a most uncomfortable position—namely, at a lower level than the elbow. For skin-grafting the author appears to prefer the older method, and says of Thiersch's grafts that "the pain is rather severe when the shavings are cut." This is not so if the shavings are really thin and include only the apices of the papillæ, and we are inclined to think that Dr. Roberts cuts these grafts too thick, especially as we notice that he merely states that "the shavings should not include the entire thickness of the skin," implying that they may include nearly the whole thickness. It is a pity that the illustration on page 529, representing dislocation of the jaw, is attributed to Ashhurst, for it is really taken from Fergusson's Practical Surgery, where it appeared more than 50 years ago.

The portion of the work that seems to us to be especially good is that dealing with the treatment of hæmorrhage, and we do not remember ever to have seen put more clearly the reasons for the correct treatment of primary and secondary hæmorrhage. We have been much pleased with many parts of the work and we consider it a useful addition to surgical literature.

Die Technik der Speziellen Therapie. Von Dr. F. GUMPRECHT, Professor in Jena. (*The Technique of Special Therapeutic Measures.*) Second Revised and Enlarged Edition. Jena: Gustav Fischer. 1900. Super royal 8vo. Pp. 354. With 182 illustrations. Price 7 marks.

PROFESSOR GUMPRECHT has undertaken the difficult task of writing a book the object of which is to enable students and practitioners to carry out "without further instruction" those clinical procedures and minor operations which are in every-day use. He supplies a great deal of that information about them which, as a rule, is only gathered *vivâ voce* from teachers in cliniques and tutorial classes. The obstacle to the success of such an undertaking lies in the fact that it is almost impossible within the limits of a book to remove the multifarious difficulties which perplex the student in connexion with these operations. Although we do not think that the author has altogether succeeded in his attempt there is no doubt whatever that he has written a very useful book and, judging by the demand for a second edition some 20 months after the publication of the first, one that has distinctly supplied a want.

The book is divided into sections according to the region affected. In each section the anatomy of the parts is explained concisely, the more important points being illustrated by diagrams. The instruments which are used and the method of their employment are described in detail and attention is directed to the accidents which are liable to occur during their use. A few references to the literature are appended to each chapter. The opening section deals with puncture of the skin for anasarca, phlebotomy, transfusion of blood, and saline solutions; another with the œsophagus and the methods of examining it; and a third gives minute directions for washing out the stomach and illustrates a variety of instruments employed for this purpose. In the chapter on Local Treatment of the Nose, Naso-pharynx, and Larynx Professor Gumprecht takes the average reader somewhat out of his depth—it will fall, for instance, to the lot of few practitioners to swab out the whole larynx—and at times he seems to forget the class of reader for whom he is writing. After a paragraph on the galvano-cautery of the hypertrophied inferior turbinated body he describes at some length the after-treatment with methylene blue advocated by Bresgen, a mode of treatment which is somewhat complicated for a beginner. The practitioner, moreover, will probably find that the good results frequently obtained by this method hardly compensate for the annoyance of occasionally seeing his patients with their faces or teeth stained blue. For the removal of adenoids the author anæsthetises only unruly children, and when an anæsthetic is required he recommends that the patient should be recumbent during its administration and should be raised to a sitting posture for operation. When gas and ether are employed as the anæsthetic there is no reason why the patient should be in the recumbent posture during the administration and so no need of sitting him up during the operation. When, however, chloroform is employed it is distinctly dangerous to change from the recumbent to the semi-recumbent or sitting posture; nor is it necessary in the case of dexterous operators. It cannot be too strongly insisted upon that patients who are given chloroform should be placed in the dorsal decubitus and under no circumstances raised to the sitting position.

In the chapter on the Thorax careful directions are given for tapping the pleural cavities, and special stress is laid on the importance of evacuating the fluid slowly. We are told that, as a general rule, 20 minutes should be allowed to a litre of fluid and that not more than one and a half litres should be abstracted at one time. While these rules admit of exceptions there is no doubt that serious risks are too frequently and needlessly incurred by rapidly emptying these cavities. In tapping the abdomen for ascites due to cirrhosis of the liver which is unaccompanied by much contraction, the author, following Dr. Flint and Dr. Cheadle, recommends early abstraction of the fluid and emphasises the good results which have been obtained thereby. The last section deals as fully as the limits of the work will allow with the examination of the urethra, prostate, and bladder, the different sorts of catheter are fully described, and sound advice is given as to their employment in the commoner pathological conditions of these organs.

The volume is one which the student and the practitioner will find of great value. Professor Gumprecht writes with admirable clearness and the illustrations are excellent; moreover, there is no other book of moderate size with which we are acquainted that covers the same ground.

A Treatise on the Diseases of the Ear, including the Anatomy and Physiology of the Organ, together with the Treatment of the Affections of the Nose and Pharynx which conduce to Aural Disease. By T. MARK HOVELL, F.R.C.S. Edin., M.R.C.S. Eng. London: J. & A. Churchill. Second edition. 128 Illustrations. Pp. 808. Price 21*s*.

THIS edition has been entirely rewritten since the first appeared in 1894, and in its present form it ranks amongst the best text-books on the ear and takes almost, if not quite, precedence of all modern works originally written in English. But it will be many years before Politzer will cease to hold the position that he now occupies as the authority on matters aural. The most noticeable omission in the present issue as compared with the former is the cutting out of the illustration of post-nasal adenoids which detracted not inconsiderably from the merits of the book. Among the most valuable additions are amplifications in the anatomy of the ear, the description of keratosis obturans, and a far more comprehensive and complete account of the operation on the mastoid antrum as described and modified by Ballance.

In dealing critically with a work of this class the fact must be borne in mind that it is more serviceable when giving, even in a dogmatic fashion, views at variance with the accepted ones, than when the writer from either lack of originality or confidence thrusts upon the public a *résumé* of the views of others. Mr. Hovell holds on some points views contrary to those held by numbers of well-known aurists, but when he does so he gives fully his reasons, and in our opinion thereby enhances the value of the book. The operation of removal of the ossicles in chronic suppurative otitis media is a case in point, as is also the therapeutical value of Eustachian bougies. In the former operation the author, when describing the measures to be adopted in the treatment of this form of otitis, has entirely changed his opinion, now definitely condemning the procedure which he formerly upheld.

In some parts the author in his determination to be clear runs the risk of being prolix, whilst in others, though this too is rare, the reverse obtains. We must mention a few omissions, in themselves trifling for the most part, but not immaterial in such a book as this. In the chapter on deaf-mutism there is no mention of Itard who in the second decade of the last century first demonstrated the possibility of teaching a certain proportion of these unfortunates to use their auditory nerves; again, no mention is made of the important dissections by Toynbee in relation to the connexions of the tympanic membrane with the periosteal linings of the middle-ear and external meatus. The absence of any description of chronic malarial deafness seems unfortunate, as there exists certainly a class of case presenting features differing from ordinary chronic adhesive or sclerotic middle-ear inflammation, while the symptoms occur in persons who have been afflicted with malaria. This work gives the experiences of 25 years of active work and close observation and will be equally of value to all students of aural surgery, however advanced.

Diseases of the Anus and Rectum. By D. H. GOODSALL, F.R.C.S. Eng., Senior Surgeon (late House Surgeon) to St. Mark's Hospital for Fistula and other Diseases of the Rectum, Senior Surgeon to the Metropolitan Hospital; and W. ERNEST MILES, F.R.C.S. Eng., Surgeon (out-patients) to the Gordon Hospital for Diseases of the Rectum, Assistant Surgeon to the Cancer Hospital, Brompton, &c. In Two Parts. Part I. London: Longmans, Green and Co. 1900. Pp. 340. Price 7*s.* 6*d.*

THE first 38 pages of this volume are devoted to a very full acount of the anatomy of the rectum and anus, and as it is well illustrated, it is likely to be of service to those who have not paid special attention to the subject. Fig. 2, entitled "the perianal region," is simply a reproduction of a photograph of a healthy perineum, and is surely unnecessary. The other matters dealt with in this part are abscess, fistula, fissure, and hæmorrhoids; while tumours, stricture, ulceration, and prolapse are to be contained in the second part. As to the general arrangement of the work, it may certainly be said that the various morbid conditions are carefully described; their etiology is fully discussed and a good account of the treatment to be followed is given. The illustrations are numerous and for the most part they are clear, but some of them fail to show clearly the lesion present.

The rules given for operation in fistula in ano are distinctly good and in this connexion we may mention some observations contributed by Dr. Hugh Walsham on the association of fistula with pulmonary phthisis. Clinically, among 891 cases of phthisis there were five cases of fistula in ano and two of ischio-rectal abscess, and of 133 post-mortem examinations in cases of phthisis only one fistula in ano was found, and Dr. Walsham expresses himself as strongly in favour of operation for this condition in patients suffering from pulmonary tuberculosis.

In speaking of the contra-indications of operations for piles the authors do not say one word as to the advisability of not operating in cases of portal obstruction. They do, indeed, say that "in those patients in whom there is a well-marked tendency to a plethoric habit of body ..... the removal of the piles is inadvisable," but no mention is made of the importance of the communications with the portal system. In the treatment of internal hæmorrhoids the authors advocate ligature and tell us that they never employ any other method. Their objection to every one of the clamp methods is on the ground that with the hæmorrhoid some healthy mucous membrane must be removed also, while they consider that Whitehead's operation leads to a severe loss of blood, is tardy in healing, and is liable to cause ultimate contraction of the lower part of the rectum. All these objections are imaginary and none of these evils result when operations are carefully performed.

It has often been said that at the present day medical men cannot write Latin prescriptions, and this statement seems probable when we find two hospital surgeons combining to write "fiat pulverem."

The Sick and Wounded in South Africa: what I Saw and Said of Them. By Mr. BURDETT-COUTTS, M.P. London: Cassell and Co. 1900. Pp. 260. Price 1*s.* 6*d.*

CARLYLE in his essay "On History" says: "The old story of Sir Walter Raleigh's looking from his prison window on some street tumult which afterwards three witnesses reported in three different ways, himself differing from them all, is still a true lesson for us." This story comes inevitably to our minds as we read Mr. Burdett-Coutts's plain straightforward statement. He has, he tells us in his preface, put down everything that he has said or written on the subject in public and we are quite certain that Mr. Burdett-Coutts has put down nothing but what he actually thought he saw. That the Army Medical Department was quite undermanned and that there was a deplorable amount of sickness and suffering we are certain is the case. But that to use Mr. Burdett-Coutts's own words (p. 221), "the things I saw and described were in a large measure preventable" we take leave to doubt—i.e., so far as regards Bloemfontein. That matters in the base hospitals improved after the publication of the famous Article IX. is, we think, without doubt, but with regard to matters at Bloemfontein, which undoubtedly were very bad, the whole question may be summed up in one word—namely, "transport." As we said in our issue of July 14th, 1900, the troops arrived at Bloemfontein physically exhausted and dependent for supplies upon a thin and precarious line of transport. On an occasion such as this was everything had to give way to the demands of the fighting line. We think, moreover, that the epidemic of enteric fever which so suddenly broke out on a large scale at Bloemfontein could not have been foreseen any more than the exceptional conditions at Paardeberg and Bloemfontein, which gave rise to it, could have been foreseen. We give Mr. Burdett-Coutts every credit for his statement, but further criticism of his words and writings must be left until we can deal with the just published Report of the Special Commission.

LIBRARY TABLE.

Atlas der Anatomie der Sternhöhle der vorderen Siebenzellen und des Ductus Nasefrontalis mit erläuterndem Texte und Bemerkungen über die Behandlungen der Sternhöhleneiterung. (Atlas of the Anatomy of the Frontal Sinus of the Anterior Ethmoidal Cells and the Nasofrontal Canal with Explanatory Text and Remarks on the Treatment of Frontal Sinus Suppuration.) By Dr. ARTHUR HARTMANN of Berlin. Wiesbaden: Verlag von J. F. Bergmann. Glasgow: F. Bauermeister. 1900. Price 16 marks.—Dr. Hartmann

has long since made for himself a name as an earnest worker and a lucid teacher, more especially in the field of otology; this Atlas will serve to bring his researches to the knowledge of those who have not been aware of his previous utterances upon the subject. The text is brief, the matter is clearly and concisely written, and the greatest attention has been paid to keeping things in their proper order and separate. The first part contains in chronological order quotations from various well-known German anatomists, with a critical *précis* of Killian's account of the embryology of the part. The author then tells us that the dissections depicted in the Atlas are characteristic examples selected from his collection, in order that the anatomical varieties may be shown to be due to the laws which influence the body generally and thereby the anatomy and the embryology of the part brought into line. He classifies the known irregularities of the sinus and frontal cells under the following:—1. Frontal sinus without frontal cells and without naso-frontal canal: (*a*) with a simple orifice either round or slit-like in the middle meatus; and (*b*) with a nasal orifice obstructed from below by the bulla ethmoidalis. 2. Frontal sinus and cells through which a naso-frontal canal is formed: (*a*) with the cells in a regular order; and (*b*) with the cells irregular. 3. Hernia-like encroachment on the frontal sinus. 4. Absence of the frontal sinus. These are all illustrated in the 12 plates, each of which contains, most beautifully reproduced, two dissections. The remarks on the operative treatment are thoroughly practical, and the work will be valuable as a handbook of reference to both anatomists and surgeons.

King's College Hospital Reports. Vol. VI. Oct. 1st, 1898, to Sept. 30th, 1899.—Dr. John Curnow continues his interesting historical sketch of King's College and of King's College Hospital. In the present section, amongst other information, Dr. Curnow recalls the part played by Professor Partridge in the trial of Bishop and Williams for the murder of Carlo Ferrari, whose body they afterwards tried to sell for dissection. Four obituary notices of old King's College men follow—namely, Sir William Priestley, of whom Dr. William Playfair contributes a sympathetic notice; of Joseph Lavies, famed outside his profession as an admirable amateur actor; of Captain Matthew Louis Hughes, R.A.M.C., killed in action at Colenso; and of Frederick Henry Corbyn. Original articles by members of the staff, with reports from the various departments of the hospital and school, together with a table of "What Old King's Men are Doing," complete the number.

Atlas der Nasenkrankheiten. Enthalten 356 Figuren in 475 Einzelbildern auf 38 Tafeln. (*Atlas of Diseases of the Nose.* Containing 356 figures of 475 separate drawings in 38 plates.) By Hofrath Dr. ROBERT KRIEG (Stuttgart). Stuttgart: Ferd. Enke. Glasgow: F. Bauermeister. 1900. First and second parts, 6*s.* each.—The Atlas of Diseases of the Larynx published in 1892 by the same author has served as a model for the present work, which is being issued in seven parts with five or six plates in each. These plates are certainly very well drawn, though, as in all coloured reproductions, the difficulty of obtaining flesh tints without making the price of a book prohibitive has not failed to leave its mark. The author has with few exceptions confined himself in the text to a short, and at the same time clear, description of each figure. On page 11 is a scheme of septal deviations, spherical deviations, and scoliosis nasi, which is an extremely useful and valuable addition. Dr. Robert Krieg gives the descriptive text in both German and English which will make the work of greater general value, though the translator is most obviously unable to throw off the fetters of German syntax as this quotation will show; "..... Do not belong from an embryonic point of view, as they are situated in the middle line of the azygos-formed frontal process, to the arrests of development of the (complete) facial clefts"; and there are numerous words translated too literally and without necessary freedom, as "unpaarig" by "azygos," and "blasenformige Deviationen" by "vesicular deviations." "Fensterresection" is not translated, neither is "Filtrum" nor "Hakenforsatz," though a literal rendering would in either case have been ample, as "window resection," "infiltration," "unciform process," and would at the same time have made the meaning comprehensible. Again, why should "Kartoffelnase" be translated and "Wulstlippen" not? The following are dealt with in the first two parts: dermoids and fistulæ, minor deformities, deviations of the septum, spurs and crests, deviations and deflections, and eczema and innocent growths.

Mrs. Beeton's Cookery Book. New edition. London: Ward, Lock, and Co. Pp. 312. Price 1*s.*—This is an excellent book. It is very full and yet very simple. Good cookery—we refer, of course, to the principles of the art and not to the higher flights—is perfectly easy if the cook will only take a little trouble, have a good fire, and use a little common sense. We are glad to see that Mrs. Beeton (p. 59) says that frying a chop or steak destroys both flavour and quality. Nevertheless, she gives a recipe (p. 110) for frying steak, but we suppose concessions have to be made to want of taste. One test of a good cookery book, to our minds, is the directions which it gives for making a baked custard pudding. There is nothing better when well made and nothing more abominable when badly made. Who does not know the nauseous concoction made of what are euphemistically called "cooking eggs," over-sweetened and baked in a quick oven, with the result of producing lumps of coagulated, stale albumen floating in a yellow watery liquid? This is what the average cook calls a custard pudding and offers to an invalid. Mrs. Beeton's recipe (p. 212) is good but not very clear, for we cannot make out whether she means that the milk when put into the saucepan with the sugar and the lemon is to be heated or no. Also, it is better to add the nutmeg after baking and not before, for in the latter case the aroma of the spice is driven off in the oven. The amount of sugar—a quarter of a pound to one and a half pints of milk—is surely excessive, but we are glad to see stress laid upon the necessity for a *very slow* oven. The book is worth much more than a shilling.

What is Life? or Where are we, What are we, Whence did we come, and Whither do we go? By FREDERICK HOVENDEN, F.L.S., F.G.S., F.R.M.S. Second edition with Appendix. London: Chapman and Hall. 1899. Pp. 308. Price 6*s.*—We like the author's choice of facts for the purpose of elucidating the great problem, however much we may dissent from his deductions. He has drawn largely from the works of Laing, Huxley, Graham, Winwood Reade, Ernst Haeckel, present-day scientists, and others, and thus has collated a selection of excerpts from a series of deep-thinking men who command the attention of every earnest student of the subject. The book is divided into Part I., The Statement of the Case; and Part II., The Evidence proving the Statement of the Case. The former occupies two pages, and the latter over 300. Ether as the one great agency by which atomic, molecular, or whatsoever force we like to call it is manifested is his creed. Then, what is ether? Ether is yet "behind the veil," and the author has succeeded in lifting the veil hardly high enough for gaining the merest glimpse of the vista beyond. The attempt to paraphrase "Consider the lilies of the field" is execrable. The poetry of the Bible is unassailable.

The Nineteenth Century: a Dialogue in Utopia. By HAVELOCK ELLIS. London: Grant Richards. 1900. Pp. 166. Price 3*s.* 6*d.*—"They were talking about a period that lay

in the dim and remote past—the nineteenth century of the Christian era." And the conversation was carried on by a youth of inexperience and an elder man, a student of the little known nineteenth century. This retrospective review of our present institutions and customs is hardly flattering to the intelligence of our cotemporaneous civilisation. As for these criticisms from Utopia, *ex uno disce omnes*. Speaking of our countrymen of the present time, the elder man remarks: "They revelled in filth, disease, and luxury. We may be sure they knew what suited them best, and their whole constitution and civilisation *was* born of that revelry." This philosophic "looking backwards" has this grain of comfort in it: it infers that our present mistakes and experiments constitute stages in the evolution of what Mr. Havelock Ellis regards as Utopia.

JOURNALS AND MAGAZINES.

THE *Practitioner* will certainly be a more useful periodical in consequence of the method which is to be adopted in its future numbers and which gives to the January number—in which it is for the first time employed—a cohesion and an easiness of comprehension which are wanting to a magazine of this kind where many diverse subjects are treated in more or less limited articles. One particular subject is to be the keynote of each monthly issue, and the more important articles will all bear directly from different points of view upon the matter selected. In the January number rheumatic fever is the subject. Dr. Arthur Newsholme writes upon the Epidemiology of Rheumatic Fever. His most important conclusions relate to its seasonal incidence, to its proclivity for urban rather than rural populations, and to the relation of dry subsoils to its infective origin. Dr. Newsholme's strictures upon the popular association of rheumatic fever with dampness and wet—due, he maintains, to the confusion introduced by "rheumatism," a condition which is probably unrelated to the specific disease—find a quaint contrast in the remarks of Dr. StClair Thomson a few pages further on, where cold and wet are regarded as etiological factors definitely known to be common to rheumatism and to sore-throat. In Dr. Thomson's article generally there is too little care taken to confine the term "rheumatism" to the specific acute disease which is meant to be under discussion in this number of the *Practitioner*. His otherwise valuable treatment of the relationship between rheumatic fever and the various forms of acute affections of the throat generally and tonsils in particular is in this way somewhat depreciated. Dr. F. J. Poynton's contribution deals with the Pathology of Rheumatic Fever and terminates with an account of the diplococcus discovered by Dr. Alexander Paine and himself, and already fully described in THE LANCET.[1] Dr. G. A. Gibson deals with the Effects of Rheumatic Fever on the Heart and makes interesting observations upon the endothelial cells of the vascular system and the possible effects of organisms and toxins in producing vegetations upon the cardiac valves. His article includes a short account of treatment, and, in common with the other authors who refer to the matter, he strongly insists upon the importance of prolonged rest after acute symptoms have subsided. Dr. A. P. Luff, who deals especially with treatment, lays down eight weeks as the usual period during which a patient the subject of an attack of acute rheumatism should be confined to bed—that is to say, if the heart is in any way involved in the attack. His remarks on treatment are sound and comprehensive, but include nothing particularly new. Cold baths are recommended for those unusual cases in which there is severe hyperpyrexia. Dr. George F. Still writes on Rheumatism in Childhood, and he emphasises what is already of course well known—the latency of symptoms. He mentions several interesting details which though really always indicative of rheumatic disease are only too commonly ignored and misinterpreted; such, for instance, are headache, pains in the side, and symptoms of hip disease. A Review of the Medical Sciences deals largely with rheumatic fever.

Progressive Medicine: A Quarterly Digest of Advances, Discoveries, and Improvements in the Medical and Surgical Sciences. Edited by HOBART AMORY HARE, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia; Physician to the Jefferson Medical College Hospital, &c. Vol. IV. 1900. London: Henry Kimpton.—We have been able to speak very favourably of the earlier volumes of this Digest, and the present number is fully equal to those which have preceded it. Dr. C. G. Stockton of Buffalo has contributed an article on the Diseases of the Digestive Tract and the Allied Organs. Fremont's researches are described here on the value of drugs in increasing gastric secretion. Fremont found that both the total free acids and total chlorides were increased by many substances, especially by white wine and gentian, while strychnine and pilocarpine had much less effect. These are curious results and not fully in accord with clinical experience. A valuable discussion is that devoted to the subject of the relation of tetany to dilatation of the stomach; the connexion is undoubted but the explanation is by no means clear. Dr. W. T. Belfield of Chicago writes on the Genito-urinary Diseases in the Male and Syphilis. During the last few years it has gradually been recognised that gonorrhœa is not the sole cause of purulent urethritis and Dr. Belfield has given a very clear account of the present state of our knowledge on this subject. He shows that other pyogenic organisms besides the gonococcus may give rise to a purulent urethritis; that there is also a non-bacterial venereal urethritis, perhaps from the gonococcus toxins or other toxins; and lastly, that there may be auto-infection of the urethra from colonies of bacteria in the recesses of the genital canal. Dr. J. C. Bloodgood of Baltimore contributes the section on Fractures, Dislocations, and Amputations. A valuable portion of this article is that dealing with emphysematous cellulitis, and details of 22 cases are given which show that on early diagnosis depends the possibility of a favourable result. Dr. Bloodgood urges that in any recent wound with infection, coverslip preparations should be made from the fluid in the wound. If the diagnosis is made early and the destruction of the softs parts above is not extensive, free incisions with immediate continuous bath treatment should be tried, and if the general symptoms of infection are not relieved amputation should be done at once. The article on Coxa Vara is exceedingly good. Dr. J. Rose Bradford has written on the Diseases of the Kidneys, and we may specially mention the article on Uræmia. Dr. A. P. Brubaker has contributed an account of the recent progress in Physiology and Dr. T. H. Gerrish has written on Anatomy. The latter article contains a most useful account of the principles of a reformed nomenclature in anatomy. Dr. H. B. Baker's paper on Hygiene is valuable, especially that part dealing with the etiology of rheumatism. Dr. E. Q. Thornton has collected in a Therapeutic Referendum a number of prescriptions and therapeutic notes on many diseases arranged in alphabetical order. The publication is likely to prove of value to all who wish to keep abreast of the incessant progress in various branches of medical science.

[1] THE LANCET, Sept. 22nd (p. 861) and 29th (p. 932), and Oct. 20th, 1900 (p. 1136).

NEW WORKHOUSE INFIRMARY, SKIPTON.—The formal opening of the new infirmary of the Skipton workhouse took place on Jan. 12th.

THE LANCET.

LONDON: SATURDAY, JANUARY 26, 1901.

The Death of the Queen.

QUEEN VICTORIA is dead. Her country and its vast dependencies are plunged in grief, while nations which owed her no allegiance and which bear no love for her subjects are moved to respectful sympathy. During the past weeks there were rumours abroad which hardly reached the general public that all was not well with Her Majesty, and those best informed were aware of her failing powers, but were loth to give currency to apprehensions that in the course of events might not have been justified. To the mass of her subjects the reports that first found their way into the newspapers on the afternoon of Friday, the 18th instant, came as a shock for which they were wholly unprepared. They had learnt to associate old age with their QUEEN and yet to forget that old age of all things cannot last for ever. They knew that less than a month ago she had been among the first to greet Lord ROBERTS on his return from South Africa, they had perhaps observed that she had since granted him a second audience, and if the matter had rested in their minds it had remained as an impression of the vitality of their aged monarch, a proof of the keen and critical interest taken by her in the affairs of her kingdom and of her personal solicitude for those who served her. Directly, however, the news circulated that the QUEEN was suffering, its gravity was fully appreciated, for the bulletins that were issued in rapid succession during the following days left little room for hope. The end has now come and the empire on which the sun never sets is vainly trying to realise its loss. QUEEN VICTORIA lived to a greater age than any other King or Queen of England, and for a greater number of years than any other King or Queen she has occupied the throne. These are matters of figures and statistics. It is a fact beyond statistics that she lived and reigned in the hearts of her subjects as no other monarch has done. During the whole of her reign she had their respect, their esteem, and their sympathy; but during the closing years of her life she held their love in an ever-increasing degree, until it can fairly be said that loyalty to the Crown was merged in deep personal affection for its wearer.

The enthusiastic greeting which she received in 1887 on the occasion of the jubilee of her reign was eclipsed by the heartiness and unanimity of goodwill that followed her through the great procession of 1897, and that acclaimed her name on that occasion wherever her subjects were to be found. It might have been thought that the devotion of her subjects had reached its highest point on that day of rejoicing, but such was not the case. QUEEN VICTORIA knew how to draw her people still closer to her. Affectionate respect for her as a good ruler and loyal admiration for her as the fitting centre of a great historical pageant were both to be reinforced by the deep love that is born only of close personal sympathy. The nation was tried by war and the heart of the QUEEN bled with the hearts of her people. Acquainted with grief, she set her subjects a magnificent example of fortitude; while her anxiety, not only for the national cause, but for the well-being of every man and every relative of every man on the battlefields of South Africa, knit the heart and brains of the empire into passionate patriotism and fervent devotion to her person. Of her own motion, prompted by no advice from her Ministers, she visited in 1900 the one portion of the United Kingdom the goodwill of which towards the Crown was not altogether beyond question; and in Ireland she met with an unrestrained expression of loyalty, while her visit left the world wondering at the energy and courage which prompted her to undertake so formidable a public duty at her advanced age. Such incidents, too, as her visit to Bristol had an effect far beyond the limits of the locality selected for honour. Moreover, Her Majesty during the past year when in London drove freely among her subjects, selecting streets not usually visited by her and giving sufficient notice of her intention to enable all who desired to be there to see her. And the crowds that availed themselves of the opportunity testified with one voice to their love. No doubt the South African war, both in its origin and its developments, has drawn the inhabitants of these islands and their fellow subjects beyond the seas closely together, but the predominating factor in this union has been the evoking of a common and wonderful loyalty towards the QUEEN, whose subjects, alas, they no longer are. That she should live to see the war concluded and peace in her dominions would have been the first wish uttered by all had it been realised that her end was drawing near, but

although this crowning pleasure was denied to her, it is impossible that she should not have felt and rejoiced in the boundless devotion which the sad necessity of a bloody war called forth from her people.

The reign of QUEEN VICTORIA has been a great reign as well as a long reign. She saw her subjects in the United Kingdom alone increase numerically from 25,650,000 to numbers which the coming census is likely to establish as well over 40,000,000, and she saw the increase of their material prosperity as well in nearly every part of the kingdom. She saw as the result of Parliamentary reform House of Commons after House of Commons, each equally loyal to herself and her Crown but each more truly representative of the people which under her it governed, each more active in framing equal laws, in bringing justice to the door of the lowliest, and in protecting rich and poor alike from oppression and wrong. She saw established a system of education which has placed within the reach of the children of her humblest subjects knowledge which in the early days of her reign was beyond even the rich, and she saw accompanying the growth of humanising influences the diminution of crime and the institution of more kindly laws for dealing with the criminal. She saw the disabilities placed upon some of her subjects owing to their religious beliefs removed and the advantages of the great universities thrown open to all; she was served by Roman Catholics and by Jews upon her Privy Council, she had one Roman Catholic as her Home Secretary and another as her Lord Chief Justice, and a strict member of the Hebrew faith as her Solicitor-General and her Master of the Rolls. The progress of science and of medicine were revealed to her in her legislative measures, for she gave her Royal assent in due course to laws which were the natural result of scientific discovery applied for the preservation and protection of her subjects' health by means undreamt of when she ascended the throne.

If the changes that QUEEN VICTORIA witnessed at home were in the nature of peaceful revolutions she endured full measure of anxiety as a sovereign in the contemplation of foreign affairs. At every period of her reign—in Europe, in Asia, in Africa—her armies were engaged in struggles more than one of which might have resulted in national calamity, and she felt the strain of such crises even in the last years of her long life. Let us hope that such anxiety may have had its compensations, for Her Majesty saw her colonies increasing beyond the anticipations of the most sanguine prophecy, while she felt in the last years of her life the strength of their support and the overflowing warmth of their devotion to her person. And in all events during the 63 years of her reign QUEEN VICTORIA so bore herself that she was Queen in deed as well as in name. Her influence was felt in every part of her dominions with authority, notwithstanding the fact that she was never in collision with the will of her Ministers or of those whom her people elected to represent them in the carrying on of the Government. The thoughtful among her people have recognised, and will no doubt realise more fully as time goes on, the great political power of her venerable personality in the international episodes that at different times have threatened the continuity of peace in Europe.

More fully and more generally have they recognised the force of her personality in their homes. As the central figure in a court that has been dignified without austerity, as a wife, as a widow, as a mother, and as a grandmother, she has been watched by her subjects closely and accepted as a perfect type. In their QUEEN the English nation have had an example of domestic virtue which has had an influence upon social life not easy to limit or define. It has been an influence felt from the highest to the lowest, the extent of which even those subject to it may never have acknowledged. In hundreds of thousands of the humblest homes in the United Kingdom and in the colonies the portrait of QUEEN VICTORIA hangs, and in every one of those homes little children have been taught, and will be taught, for generations to revere her name not only as that of a great Queen, but as that of a good Queen. No one can estimate to what extent the beautiful private life of the QUEEN may have benefited the world by thus setting before it a conspicuous example of right living and right thinking.

To the PRINCE who succeeds to the vacant throne and to every member of the Royal Family of which QUEEN VICTORIA was the head we tender our respectful sympathy, as do all her bereaved subjects. We tender it to her sons and her daughters and to all those of her younger descendants, to whom throughout their lives she will be an example. It must be some consolation to them to know the heartfelt sorrow with which millions in all parts of the globe mourn for the QUEEN who has found her well-earned rest. They can rely upon the sincerity of the expressions of sympathy that are reaching them on every side. There is no lip-service in the universal mourning for QUEEN VICTORIA. The world weeps.

Reciprocity in Medical Practice.

THEORETICALLY we are all in favour of reciprocity between countries in the recognition of medical qualifications; but practically the realisation seems impossible. Two pamphlets lie before us, by Dr. EMIL AMBERG of Detroit, Michigan, which give a very interesting account of the position in the United States as to the recognition of the qualifications of one State by the medical authorities of another. It may seem to us now in the United Kingdom very curious to find one American State looking on the qualifications of a neighbouring American State as foreign diplomas and exacting from their possessor, wishing to practise, subjection to a fresh examination; and this, though it may be a matter of notoriety that the standard of examination for the diplomas which the stranger has is infinitely higher than that for the diplomas of the State in which he seeks the right to practise. But it is little more than 40 years since the medical authorities of one division of the United Kingdom looked with as much jealousy and disparagement on the diplomas of another division as if they were altogether foreign diplomas. The Act of 1858 abolished this discreditable limitation of qualification among us, and laid the foundations of a better understanding between the members of a great liberal profession and of a higher general standard of medical education throughout the country. Theoretically, we repeat, this principle is one that must have an ever-extending application. As the commerce of the world increases, as the languages of different nations become better understood, as civilisation and all its amenities extend, the recognition of scientific and professional accomplishment must have a wider and more generous recognition. But as yet the practical difficulties are immense, and the two pamphlets before us by Dr. AMBERG, describing the dissensions of the States in America, show us why the progress of this principle is so slow. Whatever the difficulties of international reciprocity we should expect none to be insuperable in the case of the citizens of one country, yet the holder of the licence of the Medical Board of one State in America is regarded in most of the other States as an unqualified practitioner and perhaps taxed, as an "itinerant physician," $50 per annum, as in the Territory of Alaska. The cause is not far to seek and the study of it will help us to see the practical reasons which ought to make every country careful not to settle so difficult a matter on merely sentimental grounds.

The great object of legislation in regard to medical qualifications in all countries is to secure competency in those who receive licences to practise. The only way to attain this security is by regulating the number of bodies having the power to grant qualifications, by depriving them of excuses for competing downwards in such work, and by supervising the work that they do with competent and independent inspection. The multiplication of medical colleges and corporations with power to grant licences, beyond all inspection and control by a supervising or central body, is the sure way to lower standards and to retard and to degrade medical education at the expense of the public. This is the unhappy state of matters in the United States which constitutes almost the despair of those responsible for American medical education, than whom there are none in the world more anxious to promote the advance of medical science in the interest of the people. The United States have a population of nearly 70,000,000 and their medical schools multiply like mushrooms. There are no less than 156 medical colleges, with 24,119 students, providing in the populated parts of the country a medical man to every 600 of the population. In addition to the colleges which, whatever their standard, do aim at a proper professional education, there are at the present moment in Chicago, and probably in other parts, institutions for the sale of bogus diplomas. Communications on this subject were made to the last meeting of the General Medical Council by the Privy Council, and the authorities in Chicago are doing their best to exterminate such institutions. But they exist, and the existence of them is frequently referred to by Dr. AMBERG or his correspondents. And the majority of the genuine medical schools are unsatisfactory. Most of them are private institutions in which the teaching is very inefficient. Boards, State and Territorial, are supposed to control their work by holding examinations, but, according to Dr. AMBERG and the universal testimony of all serious medical teachers in the principal States, this control is inefficient. The curriculum of one State differs from that of another as the standard of medical examination does, and, worst of all perhaps, there is a wide variety in the demand of different colleges in the matter of the preliminary education of their students. All this is matter of common knowledge and admission, but it is brought to light very fully in the pamphlets of Dr. AMBERG. His object has been to promote inter-State reciprocity so far as is consistent with the interest of the public, and especially so by stimulating the members of the profession in the various States to work for this purpose with the National Confederation of State Medical Examining and Licensing Boards. To this end he has put himself into communication with the profession and with the authorities intrusted with carrying out the rules governing the practice of medicine in the different political divisions. The answers of these authorities show that they are generally in favour of reciprocity but are afraid of its application while the conditions of medical qualification in the different States are so various and so unsatisfactory.

We heartily sympathise with Dr. AMBERG and his many earnest colleagues in their desire for such legislation as will give uniformity and efficiency to medical education in the United States and so will pave the way for abolishing all territorial limitations of qualifications. It would, of course, be well if the States that have inferior medical schools and examinations would recognise without reciprocity the diplomas of those States that are more exacting, while private schools granting degrees and diplomas, even if their attempt to maintain a decent standard seems genuine, had better be suppressed. The lesson to be drawn by us from the transatlantic position is obvious, for the difficulties so strikingly exhibited in regard to inter-State reciprocity are only an illustration of the larger difficulties of international reciprocity. Where there is no power of controlling medical

education or of inspecting medical examinations reciprocity is open to the greatest objections, which will become more and more apparent when the experiment comes to be tried. It is to be hoped that the Government of this country will not proceed too rapidly in this direction, or, indeed, proceed at all, without taking the General Medical Council into consultation as to the practical difficulties to be encountered.

The Indian and Colonial Addendum to the British Pharmacopœia.

IN the recognition of the employment of different drugs in different parts of the British Empire it might at first be considered that a retrograde step had been taken; in reality, however, it will be found that there is a distinct advantage in collecting in one official standard all that concerns the drugs likely to be employed by British subjects wherever located. The publication of the Indian and Colonial Addendum to the British Pharmacopœia shows clearly the trend of thought during the latter part of the last century and affords another hopeful sign for the future unification of our Empire. Of late years there have been many indications of an increasing attention to medical matters connected with distant parts of the Empire. Even before the anxieties in South Africa absorbed so much thought and energy there had been a wave of interest in tropical medicine from which certain hopeful results have already been obtained. It had been recognised that local study in our colonies and at the seats of different endemics might enlarge our conceptions of disease and that some preparation at home might facilitate such work. Meanwhile there were not wanting rumours to show that those responsible for the compilation of the British Pharmacopœia hoped to do their part towards welding together the colonies and dependencies by supplying information relating to the modifications of treatment which are frequently necessitated by local conditions.

The growth of the Pharmacopœia throws an interesting sidelight upon the history of medicine during the century, since it shows an increasing tendency to obliterate the local peculiarities of practice which formerly did much to hamper progress. The first step was the fusion of the different Pharmacopœias which were previously in use in England, in Scotland, and in Ireland, and the production of the British Pharmacopœia of 1864. Twenty years earlier a Bengal Pharmacopœia had been issued in Calcutta by order of the Government, and it was perhaps in relation to this work that in 1867 the preface to the new British Pharmacopœia stated that it was intended to afford to the members of the medical profession and those engaged in the preparation of medicines throughout the British Empire one uniform standard and guide whereby the nature and composition of substances to be used in medicine might be ascertained and determined. Although the Imperial scope was aimed at in 1867, this failed to afford universal satisfaction, since in 1868 a Pharmacopœia of India was prepared under the authority of Her Majesty's Secretary of State for India; this was edited by Dr. E. J. WARING, assisted by a committee appointed for the purpose. This book was avowedly based upon the British Pharmacopœia, and while affording all the information contained in that work which might be of practical use in India it combined with it certain supplementary matter intended to meet the requirements of the Indian Medical Department. One of the primary objects was the introduction of the indigenous products of India into European practice in that country; this was facilitated by the inclusion of much information relating to their medical properties and therapeutic uses. This work is practically the origin whence the present Indian and Colonial Addendum has developed, since it suggests that India yields efficient substitutes for some of the drugs which are in the British Pharmacopœia, while it speaks of the advantages of employing remedies which are at hand in the remotest corners of the Indian Empire, so that India may be to a certain extent independent of "costly imported articles." So far as India was concerned the protest made in 1868 by Dr. WARING'S Committee against the limitations of the British Pharmacopœia took this form. Some official drugs were not obtainable in India, some could not be imported, and for both classes there were efficient substitutes of native growth. What was true for India held good for many of the colonies, but in Canada the need of local modifications was rendered more urgent on account of the existence of the United States Pharmacopœia, which was to a certain extent a source of difficulty if not of danger. The difficulties arose from the dread of confusing the two standards, since there were differences in the percentage composition of many articles which bore the same name, and the dispenser might not uncommonly be in some doubt as to the intention of the prescriber. These details were obviously kept in view during the preparation of the British Pharmacopœia of 1898 which exhibited a marked attempt to secure greater uniformity in the standards of purity and a gradual approximation of pharmaceutical processes. The adjustment of differences will, however, require much greater interchange of opinion, and meanwhile the influence of American practice on medical work in Canada is sufficient to warrant the inclusion of several new drugs and preparations in an addendum of Imperial scope.

The idea of strengthening the bond of union between different parts of the Empire has long attracted the Pharmacopœia Committee of the General Medical Council. The late Sir RICHARD QUAIN took a deep interest in the subject and initiated many of the inquiries in the earlier stages. It was at one time hoped that the results might be incorporated in the issue of 1898, but this would have entailed delay and although numerous modifications were then recognised from tropical countries the introduction of new remedies was postponed. The late Dr. LEECH, who succeeded Sir RICHARD QUAIN as chairman of the Pharmacopœia Committee, extended the inquiries, formed a collection of Indian and colonial drugs, and performed numerous experiments, especially with mylabris, the beetle suggested as a substitute for cantharis. The work was far advanced at the time of his death, and the value of his share in it received touching recognition both in the preface to the Addendum and in the report of the Pharmacopœia Committee of the General Medical Council. Dr. LEECH was followed as chairman of the Pharmacopœia Committee by Dr. DONALD MACALISTER who threw himself into the task with so much energy that no delay in

publication resulted. It is impossible to mention all who have contributed to the issue of the Addendum. Various administrative bodies in India and the Colonies have, through Her Majesty's Privy Council, the India Office, and the Colonial Office, afforded valuable information which has been collated by the editor, Dr. JOHN ATTFIELD, who has shown discrimination and untiring labour in the editorial function. Dr. ATTFIELD has received much help on questions of pharmaceutical botany from Mr. W. KIRKBY of Manchester and Mr. E. M. HOLMES of the Pharmaceutical Society. The general supervision of the work has been in the hands of a committee of the General Medical Council, with the assistance of Dr. NESTOR TIRARD as secretary. All these gentlemen may well be proud of the result of their work.

Annotations.

"Ne quid nimis."

TEMPERANCE IN THE ARMY

THE prevalence of intemperance in the army, still an unfortunate fact, has lately occupied a place of more than its usual prominence in the columns of the daily press. One writer on this subject reminds us that there are over 100 licensed houses of one kind or other in Aldershot alone, almost all of which have been established since the camp was formed there. He strongly protests against a similar liberality in the granting of licences in other and newer military centres, and he advocates, wherever possible, a reduction in the excessive number of those already issued. He would encourage the growth of restaurants where first-class refreshments might be obtained but not alcohol, and he would have the barrack recreation-room develop into an institution really worthy of its name which at present it is not. These very sensible observations are fully endorsed by another writer who is also evidently conversant with the soldier's needs and his temptations. His suggestions as to the improvement of the recreation-rooms are highly practical. They provide for entertainments, for a spacious bar where beer can be sold, for a temperance refreshment-room, and for a reading-room—in fact, for a soldiers' club. He recognises that the great majority of young soldiers are disposed to be temperate and would remain so with a little judicious assistance of the kind above indicated. He condemns the present canteen system as antiquated and essentially mischievous and would have it abolished. He argues that any small additional expense incurred by the substitution for it of the proposed club would be fully repaid by the elevation of the whole tone of barrack life and the restoration to civil duties after their term of military service of a greater number of men who have not learned intemperance in the army. It is highly satisfactory to find that those who know the soldier best, from the Commander-in-Chief down, are thus willing to do battle with and for him against that vice which is truly his worst enemy. The balance of public opinion will certainly be found on the same side. Any rational scheme which will promote his sobriety may, we are assured, rely on the approval and support of the great majority of his fellow-countrymen.

THE TEACHING OF SCIENCE.

A DISCUSSION of the best methods of instilling a knowledge of natural science into the youthful mind is certain to be productive of good. There is much to be said against the present methods of education in regard to its scientific side. Unfortunately, an examination is regarded as a criterion of knowledge and so instruction is based upon the mere requirements of the examiner's sheet. What we want our teachers to understand is that the pupil does not so much want loading with facts as to have his faculty trained in the direction of extending his own powers of observation, so that later he may be able steadily and easily to acquire facts for himself. A movement is steadily gaining ground in this country which is directed towards improving our methods of scientific education so that eventually scientific knowledge may be more extensively applied to our industries. There can be no doubt that both the Germans and Americans where they outstrip us in the industrial race do so because they are alive to the importance of applying scientific knowledge to practical industry. As an inventive nation we hold the first place, but our inventions have been utilised almost wholly by other nations. As examples we may quote the great German aniline industry and the American industry for the manufacture of electric appliances. These and other subjects have been discussed during the past few days at a conference of science masters in public schools which was held in the rooms of the University of London at South Kensington. It is to be hoped that discussions of this kind will result in a better system of teaching science in our public schools for the sake of the industrial prosperity of the country.

WHAT IS "COGNAC BRANDY"?

IT is usually as a matter of chance that trade tricks and facts about adulteration come to the knowledge of the general public. The spread of knowledge as to the various substances from which beer is usually brewed forms a case in point. Some interesting information has lately been given at Dublin concerning the usual composition of brandy. A Kingstown grocer has just obtained damages from a firm of London merchants for supplying him with cognac brandy which was not of the quality that he ordered. The plaintiff stated that the spirit which had been supplied to him was unsaleable, and that one customer had returned a bottle with the complaint that he had been inadvertently supplied with benzoline. This was doubtless a pleasantry on his part, for Professor Tichborne gave evidence to the effect that the liquor was "patent stilled spirit." We must in fairness state briefly the defence which was set up. It appears to have been in part technical—that there was no contract, that the defendants had received no money, that no warranty was given, and that the brandy mentioned in the statement of claim was not that supplied by the defendants to the plaintiff. The most instructive part of the defence was contained in the evidence given by one of the defendants. He said that the liquor supplied was foreign brandy and was distilled in part from grape juice. In the trade it was called "cognac," but cognac made from Cognac grapes exclusively "did not exist on the market," and the cost price of it would be about 7*s*. per bottle. The jury found that the defendants had contracted to supply "cognac brandy, which is a blend containing a proportion of grape spirit," and that the liquor which they supplied was neither brandy nor what is known in the trade as "cognac brandy." The evidence given in this case is not very reassuring. According to the definition accepted or given by the jury cognac brandy is said to be a blend which must contain at least some grape spirit, but it does not appear to matter how small the proportion of this may be. There is no doubt that it has of late years been increasingly difficult to obtain good brandy, and for this reason, amongst others, whisky has in this country largely taken its place.

If the late Mr. Pickwick were to revisit his old haunts he would perhaps be more surprised at this than at the other changes which would force themselves on his notice. It ought, however, to be thoroughly understood that whisky cannot properly be substituted for brandy in all cases. Fine brandy contains in addition to alcohol a number of highly volatile ethers which have a strongly stimulating effect and which are eliminated without any known ill-effects and without causing the slightest derangement to the digestive system. It is much to be regretted that the *fin champagne* which was sent from France till about the year 1870 is now practically unobtainable. These liquors were not only pleasant to the cultivated palate, but, given judiciously, were most useful in many cases of sickness. Unfortunately nothing has yet taken their place. Readers who habitually follow the results obtained in our Analytical Laboratory will have noticed that our consulting chemist has often found reason to praise samples of brandy which have come from some of the English colonies. Analysis has more than once pointed to the inference that the spirit has been derived from grapes, but in practically all cases there has been a deficiency in the œnanthic ethers which are the life and soul of the ideal brandy.

EGYPTIAN VITAL STATISTICS.

IN the third and concluding part of the third fascicle of his work dealing with Egyptian vital statistics, including climate and meteorology, Dr. Engel Bey treats of mortality above the age of five years, and prefaces his remarks with the following interesting table:—

Annual Death-rate according to Age per 1000 living in each Class.

Name of city.	Cairo.	Alexandria.	Damietta.	London.	Berlin.	Paris.	Vienna.	Munich.	Moscow.
Period.	1889–90.	89–90.	86–90.	81–90.	90–91.	89–81.	90–91.	90–91.	81–83.
Years.									
0 to 5 ...	145·0	130·5	62·9	68·2	104·7	119·2	119·3	157·2	275·2
0 „ 10 ...	90·2	86·7	35·3	39·1	59·9	63·6	68·3	87·8	156·3
5 „ 10 ...	10·3	10·1	7·1	5·9	6·0	10·2	8·4	8·5	17·7
10 „ 20 ...	9·1	8·5	3·8	3·3	3·1	8·0	5·7	3·6	7·2
20 „ 40 ...	13·8	11·6	?	8·6	7·0	13·2	10·3	7·6	13·3
40 „ 60 ...	24·4	24·2	?	26·0	16·7	22·0	20·2	18·4	28·2
60 „ *x* ...	109·5	116·4	?	91·9	63·4	67·7	67·4	70·9	78·3
0 „ *x* ...	39·9	39·0	25·6	20·3	21·2	25·6	25·6	26·9	34·7

In London the higher age-groups should be as follows: 20 to 45, 45 to 65, 65 to *x*. In Moscow when the deaths of foundlings are eliminated the rate for children under five years of age falls to 191·8. In the Damietta column the information is only partially forthcoming, probably on account of a typographical error, but from the figures that appear it is evident that the ancient Nilotic seaport still maintains its character for salubrity. In this connexion our readers will no doubt remember some articles which we published a few years ago[1] in which the superior healthiness of Damietta and Rosetta was ascribed to the fact that the inhabitants could not drink Nile water when the river ran low because it then became salt from admixture with the sea. They were perforce compelled to depend on a supply stored in *sahariqs* or tanks when the Nile was in flood and when its waters were consequently still pure from a potable point of view. On this subject the following remarks of Dr. Engel in his present essay are noteworthy, for hitherto he has not formally incriminated the water-supply of Egypt. "While fully admitting the influence of heat and humidity on the organs of digestion we cannot doubt, I think, that abscess of the liver and dysentery as well as the gastro-enterites that so frequently are met with must be caused in part by the bad quality of the water—the Nile water—in the canals and wells which everywhere is polluted but not at all or only badly filtered. We must also hold the water-supply responsible as the main cause of the typhoid fever which is relatively so widespread amongst foreigners, the milk for consumption becoming infected through the water used for diluting it or for washing the vessels in which it is kept." In a general survey of his subject Dr. Engel concludes that so far as the native population of Egypt is concerned the mortality in all the age-groups above infancy is considerably higher than is that prevailing in Europe, but that amongst foreigners the limits of the latter are not exceeded. It is the Egyptian infant alone who survives in accordance with the Western scale, this happy result being due to the suckling of their offspring which is invariably practised by native mothers. Amongst children aged more than five years and adults up to 60 years the chief causes of death are phthisis pulmonalis, "typhic" fevers, dysentery, and affections of the thoracic organs. Above 60 years of age debility enters once more upon the scene as a frequent cause of death, carrying off the old people as effectually as the newly-born. Dysentery and respiratory troubles come next in order as prolific sources of mortality amongst the aged. As regards dysentery it is probable that other affections, such as enteritis and diarrhœa, are sometimes mistaken for it, but Dr. Engel is satisfied that the true disease is endemic in the Nile valley, being disseminated by means of drinking-water. Dr. Engel is also convinced of the occurrence of typhoid fever in native patients, a fact which he says has been disputed. That the affection is to be met with amongst European residents and visitors is unfortunately not open to doubt, although, happily, its ravages of late have been far less deadly than they were during the early years of our occupation. The usual number of deaths from violence in European centres, whether due to accident or to crime, is stated by Dr. Engel to vary annually between four and seven per 10,000 inhabitants, but in Egypt during the four years 1887–90 the average was 4·7, made up as follows:—accident, 4·0; crime, 0·66; suicide, 0·04. In Lower Egypt during this quadrennial period the suicides numbered 55 in all, or less than 14 per annum, but only 30 per cent. of the cases were indigenous. In Upper Egypt not a single case of suicide occurred.

[1] THE LANCET, Sept. 9th (p. 643) and Nov. 18th (p. 1274), 1893; and April 28th, 1894 (p. 1088).

THE WILL OF A GOOD PHYSICIAN.

THE will of the late Sir Henry Acland is interesting from its being the testament of one who was notable in many ways. Its concluding clause is as follows:—

"And now, with a deep sense of the mercy and goodness of God to me and mine through parents, children, and friends and by the saintly life of my dear wife gone before, I commit my soul to my Heavenly Father in the faith and love of Christ and hope for forgiveness of my shortcomings in my holy profession, and I pray that the faithful study of all nature may in Oxford and elsewhere lead men to the knowledge and love of God, to faith and to charity, and to the further prevention and relief of the bodily and mental sufferings of all races of mankind."

"In Oxford and elsewhere." The phrase is very characteristic of one whose life and thoughts were bound up with the ancient University and city by the Isis. One memorial of Acland's wish to perpetuate the connexion of Nature and Oxford exists in the Museum—a bible in stone devised by him in company with Ruskin as part of a plan to represent the Kosmos, the whole orderly creation,

in such a way as to make it intelligible to the student. Another clause in the will was to the effect that all his papers relating to his profession as a physician should be destroyed unread. This clause, while showing the deep reverence for his profession and for the duties which it imposed upon him which Sir Henry Acland felt, may be thought to be excessive in its observance of the Hippocratic oath. Some will hold that such clinical records might surely have been preserved, that accumulated evidence gathered together by a keen observer might be handed down for the benefit of future generations. But the clause shows the proper as well as honourable feeling which was characteristic of him who wrote it. No information which he had received in confidence could be imparted to another, however discreet. He alone could edit his clinical records, and this he did not do. It is not everyone who sees how strictly private such notes must be and how imperative it is that discretion should be used by those designing to publish any part of them. Not very long ago we had to comment adversely upon the incident of the sale of a number of hospital case-books after the death of a medical man who had held the post of physician to the Hospital for Women, Soho-square.[1] Such a gross breach of trust and of decorum could never have occurred if anyone had been on the managing staff of the hospital in question with Acland's nice sense of the duty of secrecy owed by the medical man to his patients.

PHARMACEUTICAL NOTES FROM THE WELLCOME CHEMICAL RESEARCH LABORATORIES.

FROM time to time reports are issued from the Wellcome Chemical Laboratories giving the results of the investigations into pharmaceutical questions undertaken at the instruction of the directors. Amongst recent publications of this kind we notice a contribution to the pharmacognosy of official strophanthus seed. As is well known, this drug possesses an interesting history. The plant was discovered in 1861 by Sir John Kirk, whose attention was drawn to it by its poisonous properties, the plant being the basis of the Kombè poison. According to recent inquiry it would appear that every histological character upon which the identification of the different varieties of Kombè seeds has hitherto been based is found almost without exception to exist in seeds obtained from one and the same pod. Previous histological conclusions, therefore, must be abandoned, as they were in favour of the identification of different varieties based upon distinctions no longer held to exist. Another interesting communication from the same laboratories relates to the composition of berberine phosphate. Pure berberine phosphate was obtained by acting upon berberine acetone with an excess of phosphoric acid and re-crystallising the product. The salt thus obtained was of a bright yellow colour and showed a composition in accordance with the formula $C_{20}H_{17}NO_4(H_3PO_4)_7$ with varying amounts of water of crystallisation. The same salt may be obtained by acting upon berberine sulphate with acid calcium phosphate. The preparation of mercurous iodide forms a subject of another note. The results show that mercurous iodide prepared by precipitation is quite uniform in composition and is sufficiently stable when properly protected. As is well known mercurous iodide is commonly prepared by triturating mercury with iodine, the final product invariably containing free mercury; and thus it is important to decide whether such a preparation, containing more or less free mercury, is preferable to the pure salt for medicinal use. The facts now available, however, are in favour of the pure yellow iodide being generally adopted. This interesting and instructive series of contributions is accompanied by some observations and suggestions relating to the chemistry of the British Pharmacopœia by the director of the laboratories.

THE LANCET RELIEF FUND.

OWING to the absence from town of some of the almoners and the temporary indisposition of Sir Henry Pitman, the auditor, the annual meeting of THE LANCET Relief Fund was not held as customary upon the first Monday of the present month. The meeting will now take place on Monday, Feb. 11th. The report and balance-sheet will be published in the following issue of THE LANCET.

LEAD-POISONING.

IT is interesting to learn from the leading representatives of the china manufacturers in this country that they are quite willing to adopt fritted glazes in the manufacture of china ware. At the same time it is to be expected that the trade generally are averse to the elimination of lead altogether for the purpose. We have already pointed out that the adoption of fritted glazes would be just as satisfactory a solution of the lead-poisoning problem as the adoption of glazes containing no lead at all. We still, however, keep to the belief that as experience is gained leadless glaze will be found to be a perfectly satisfactory substitute. It must be remembered that the application of leadless glazes is quite in its infant stage. The opinion of experienced masters of such an old and beautiful industry as the manufacture of china must be respected. They alone know the practical difficulties presented by such a drastic change as the exclusion of lead altogether for the purpose of glazing ware. Nevertheless, we know that the industry has given rise to grievous injury to health to those engaged in it, and from this point of view the subject must be approached seriously, even if it mean the condemnation of the use of lead in pottery manufacture. We believe that the compulsory employment of "frits" is a remedy which will appeal both to the practical potter and to his employé. The adoption of leadless glaze would be quite safe to the latter, though it undoubtedly would seriously affect the interests of the former.

NEW YORK ACADEMY OF MEDICINE: REPORT OF THE LIBRARY COMMITTEE.

THE report of the Library Committee of the New York Academy of Medicine states that on Nov. 30th, 1900, the number of volumes in the library was 89,000, including 36,105 duplicates. The books added during the year, not including duplicates, numbered 3649 volumes. In the circulating department 871 books and 832 journals were issued to 194 readers. 11,520 readers have registered during the year in the reading-room, and probably many others have used the library but have not registered. The library is growing rapidly, the additions annually for the last four years being at least 3500 volumes a year. In 1898, when the library of the New York Hospital was given to the Academy, 7000 volumes were added without including duplicates. 991 journals in many languages are on file and added 1135 bound volumes to the shelves during 1900. Including the duplicates the natural growth amounts to about 5000 volumes, and at this rate there is only space left for five years more. More space for the library is urgently needed and it will be difficult to find this space in the present building. At present there are 13 430 feet of shelving available, of which less than 3000 feet are unoccupied, and 600 feet of shelving are needed annually for the natural growth in new books. The labour of taking charge of this large collection of books will require an increase in the

librarian's staff this coming year. More money is urgently needed, both for the purchase of books and for the running expenses. Truly "of making many books there is no end." The cry for more room is universal throughout the libraries of the world, and the output of books increases day by day. Especially is this the case with medical literature, and the United States are more prolific in this direction than any country. The subdivision of subject-matter has made the old text-book of medicine give place to elaborate "systems," published in 10 volumes or so, or else we have fully and carefully written monographs upon one disease. The mere literature of the youngest daughter of medical science—namely, bacteriology—almost requires a library of its own, and as for periodical literature, medical journals and magazines are showered abroad like the leaves in autumn. In many of these there is doubtless a great deal of chaff to very little wheat and as no library is capable of indefinite extension some process of exclusion will before long become inevitable.

THE EXTENSION OF THE BOROUGH OF WORTHING.

THE growth of our urban, and the depopulation of our rural, districts is one of the greatest problems of modern life, and the exceptions to this rule are often more apparent than real. As a matter of fact, however, in the proximity of our large towns the rural districts in no sense suffer from depopulation, and vigorous efforts are sometimes required to prevent the population from being distributed in a manner inconsistent with healthy urban conditions. There must obviously be some limitation to the aggregation of population which can be properly administered from one centre by one administrative body, and perhaps in certain cities in the world such limitations have already been reached. But, conversely, there are obviously great disadvantages, more particularly from a public health standpoint, in the several parts of what is structurally a single town being administered by multiple authorities. This phase appears to have been already reached in Worthing, a considerable portion of which town is situated outside the borough proper, and in the rural parishes of West Tarring and Broadwater. Originally the villages bearing these names were separated from the town of Worthing by a stretch of open country, but the increased population has resulted in covering the area with habitations, and Worthing is now seeking powers to embrace both parishes within its limits. The general merits or demerits of the proposal will doubtless soon be fought out by means of a public local inquiry, but from our point of view, that of the public health, there are sundry reasons which must be held strongly to support the consolidation scheme. The rural district council administering the affairs of what may be termed the towns of West Tarring and Broadwater are hardly likely to pay as much attention to these two parishes of the rural district as their importance demands. Indeed, rumour has it that at times meetings of the rural district council are so poorly attended that a quorum is not forthcoming. Moreover, the fact that the offices of surveyor and inspector of nuisances are occupied by one and the same individual is sufficient to indicate that no very adequate supervision can be maintained over the erection of new buildings and the sanitary condition of old buildings, and we should not be surprised to hear that the roads and footpaths are not quite up to urban standard and that the lighting is bad. Houses, too, which are within a few feet of the sewers are said not to have been connected with the sewers owing to the absence of proper administrative action. As regards the control of infectious diseases the people of the rural parishes seem to be dependent upon the goodwill of Worthing; and it is, perhaps, in accordance with civic nature that Worthing should give preference to the infectious sick of its own district. In all these directions, as, indeed, in many others, there would seem to be advantage in the extension of the borough in such fashion as to focus the control of infectious diseases, the water-supply, the sewerage, and the household drainage, while in the matter of the investigation of outbreaks of disease, whether water-borne or not, the concentration of the notifications into one office cannot fail to be of value. We expect that these facts will have some influence with the Local Government Board in their determination.

MR. SAM LEWIS'S BEQUESTS TO CHARITY.

WE are happy to learn that general and medical charities will benefit largely under the will of the late Mr. Sam Lewis. The Prince of Wales's Hospital Fund for London will eventually receive a quarter of a million from the estate of the deceased money-lender, and many of the principal metropolitan hospitals have also a separate interest in the future disposition of his enormous wealth. Mr. Sam Lewis was a remarkable man. He was a usurer who conducted his business with such scrupulous honesty that he gained the real regard of his clients. Money-lending must always be a nasty trade, for it thrives on the failings of the weaker section of society and cannot allow scope for much kindness of heart. A money-lender who was moved to disregard business precautions out of sympathy with his clients' stories would in a few hours have no money to lend. Mr. Sam Lewis did his best to show that usury can be run on fair lines. He took large risks and exacted large profits, and the value of his estate shows that he neglected no means to ensure these profits accruing to him. But he received only what he compounded to receive. And in his disposition of his property he has displayed the generosity which he was obliged to suppress in his purely business relations.

ARSENIC IN BEER.

THE Manchester and Salford Trades and Labour Council at a meeting last week passed the following resolution:—

"That, in view of the serious consequences which have resulted from the sale of unwholesome and poisonous beer, this council is of opinion that it is absolutely essential, in the interests of the public, that the Government should at the earliest possible moment promote such measures in Parliament as will ensure that only pure and wholesome beer shall in future be sold to the public throughout the country. This council is further of opinion that as the health and lives of the public are involved in this question it is the duty of the Government to proceed with legislation at once upon the subject, without waiting for any report of any Royal Commission, as there is already ample evidence that very many people have of late been injured and a number killed through drinking poisoned beer, and the protection of the public demands immediate legislation without the delay which attends the proceedings of a Royal Commission."

This is exactly the view which we expressed in a leading article last week and we heartily congratulate the Manchester and Salford Trades and Labour Council on their admirable and sensible resolution. We have already pointed out that the use of malt substitutes is more a matter of expediency than economy. Indeed, as is pointed out in a letter in the *Times* of Jan. 22nd by Sir Walter Greene, who has had a large experience of practical brewing, it would appear that invert sugar may cost nearly 1s. per quarter more than barley malt. Whatever the economic considerations may be, the introduction of arsenic into beer must be effectually stopped. The inquiry at Manchester was concluded this week and the verdict is a comprehensive censure on all those concerned. The jury agreed that death had been caused by arsenical poisoning

and they returned an open verdict with a rider censuring brewers, sulphuric acid makers, and chemists alike for carelessness. The reports from the medical officers of health of the counties affected by the epidemic are coming to hand. We have received that of Dr. G. Reid, medical officer of health of the county of Stafford. According to this report 667 cases were traced to arsenical beer poisoning and these had occurred in 25 districts. The report is accompanied by a statement of the county analyst, Mr. E. W. T. Jones, who found that of 140 samples of beer analysed 15 were decidedly arsenical and seven slightly so. We note with satisfaction that the machinery provided by the Sale of Food and Drugs Act is being set in motion and followed by reports of successful prosecutions on all sides. What purpose is served by waiting for the ponderous proceedings of a Royal Commission?

THE SANITARY INSTITUTE LECTURES.

THE thirty-first course of lectures, with demonstrations, for sanitary officers will be delivered during February, March, and April next at the Parkes Museum, Regent-street, W. In the syllabus it is announced that Dr. E. J. Steegmann will deal with Mechanical Physics on Feb. 1st, 4th, and 6th, while Dr. J. Priestley will discourse on Sanitary Law on Feb. 8th, 12th, 14th and 15th. Dr. H. R. Kenwood will take for his subjects "Infectious Diseases," "Methods of Disinfection," "Water Pollution and Purification," and "Elementary Statistics" on Feb. 25th and 27th and March 1st and 4th respectively. The Signs in Health and Disease in Animals Destined for Food will be considered by Mr. W. Hunting, F.R.C.V.S., on March 29th. Dr. E. Petronell Manby will lecture on the Appearance and Character of Fresh Animal and Vegetable Foods, dealing at the same time with methods of preservation, on April 15th. Among the inspections and demonstrations in connexion with this course Mr. A. E. Harris will conduct a party over the disinfecting station at Islington on March 2nd and Mr. James King, M.R.C.V.S., will give a demonstration at the Metropolitan Cattle Market on April 15th.

THE SCOTTISH POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

THE annual report of this association, which we published in THE LANCET of Jan. 19th (p. 204), affords proof that the members are alive to the necessity of united and energetic action in order to accomplish a real reform, or, indeed, any improvement at all, in the terms and character of Poor-law medical work in Scotland. It is especially satisfactory to note that they realise that the fundamental condition of all such improvement is some legal assurance of security of tenure of office. So long as Scottish Poor-law medical officers are liable to dismissal for no assigned reason, on the action of a section of the parish council, and possibly for faithfulness in the discharge of their official duties, so long is it vain to expect any energetic or effective agitation for the removal of grievances. The report tells us that the finding of the Committee that the initial step in reform must be the securing fixity of official tenure has not given universal satisfaction to members of the association in the Highlands and islands. But members in remote parts will do well to trust those more centrally placed as to the best means of securing the ends which all have in view. Inadequate salaries, inadequate holidays, and the withholding of the whole or part of special fees are some of the special grievances which call for urgent redress. Some of these practices are inconsistent with the existing law and official rules for the guidance of parish councils and could not resist the earnest protest of a united and independent profession. Unfortunately the profession is not independent, and least of all in the very remote parts where grievances are most glaring and acute. We counsel unanimity in the support of the association, especially in its efforts to secure protection to medical officers against all capricious and unreasonable dismissals. When this reform is obtained others will follow. No time should be lost if anything effective is to be done in the coming session of Parliament.

CONGENITAL TYPHOID INFECTION.

IN the *Journal of the American Medical Association* of Dec. 29th, 1900, Dr. George Blumer relates a rare and important case of typhoid hæmorrhagic infection, probably congenital. About nine cases of congenital typhoid infection in which the diagnosis was proved bacteriologically are on record. All the cases occurred in children born when the mother was suffering from typhoid fever. In many the birth was premature. In three cases abortion took place about the fourth or fifth month, in two about the eighth month, and in two the children were born at term. Most of the children were born dead, but three lived nine hours, four days, and five days respectively. In most of the cases in which the child had reached only the fourth or fifth month the necropsy was entirely negative and the diagnosis rested on the bacteriological examination. In some of the later cases definite macroscopic lesions were present, though in all except one the intestines were spared, and in that one only a single solitary follicle was involved. The disease took the form of a general infection. The most constant lesion was slight enlargement of the spleen. Other lesions were slight icterus (two cases), hæmorrhages into the skin, liver, or kidneys (two cases), and slight swelling of the mesenteric glands (one case). The condition of the placenta is recorded in four cases. In all it was normal, but typhoid bacilli were found in it when it was examined bacteriologically. Typhoid bacilli were present constantly in the spleen and frequently in the blood, occasionally in the lungs (two cases), kidneys, and mesenteric glands (one case), and liver (one case). Dr. Blumer's case differs from those previously reported in that the mother was in good health at the time of birth. But she had an acute illness with remittent fever four and a half months previously which confined her to bed for 21 days. Presumably she suffered from typhoid fever, for she resided in a non-malarious district. A female child was delivered with forceps after a difficult labour. On the fourth day the infant had a slight convulsion after nursing. At each subsequent nursing she became rigid, as if in pain. On the fifth day there were spots of blood on the diaper. The amount of blood lost gradually increased until on the sixth day it became alarming. The vagina was packed with cotton, which was soon expelled with large clots of blood. Examination revealed an eroded cervix as the source of hæmorrhage. This was cauterised with nitrate of silver and the vagina was again packed. But the cotton was soon again expelled and vaginal hæmorrhage continued until death, which took place on the ninth day. Before death there were slight bleeding from the gums and a petechial eruption on the forehead. There were slight elevations of temperature. At the necropsy the mucous membranes were very pale. The mesenteric glands were all red and hæmorrhagic. The liver had a mottled, reddish-yellow appearance, and looked as if it had been boiled. On section it was very cloudy. The kidneys showed a few cortical hæmorrhages, and the bladder one large submucous hæmorrhage and numerous small ones. The vagina contained clots and showed two submucous hæmorrhages. The uterus was four centimetres in length and much dilated. Above the internal os was a blood-clot of the size of a pea.

A strip of endometrium one centimetre wide was intensely hæmorrhagic. The solitary follicles in the ileum and large intestine were swollen and some of them contained hæmorrhages. Microscopically, the liver cells were swollen and fatty, and the renal epithelium was swollen and granular. In the intestinal follicles the lymphoid cells had partly disappeared and were replaced by large epithelioid cells; in stained sections short bacilli were seen. The endometrium showed cell proliferation and hæmorrhages. Cultures from the heart's blood, liver, and kidney were negative; cultures from the colon, lung, umbilical cord, bile, and spleen yielded the typhoid bacillus. The septicæmic character of the disease is characteristic of congenital cases and hæmorrhages are common in them.

A DANGEROUS ECONOMY.

A CUSTOM of the City more to be honoured in the breach than in the observance was explained at the Guildhall police-court the other day by a police-inspector and seems to have been new to the presiding alderman. It consists in the police refusing to summon a medical man to examine a prisoner who denies being drunk when charged unless he or she is able to produce 7*s*. 6*d*. to pay the necessary fee. In the case in question an inspector explained that the difficulty lay in the fact that if the person desiring to be medically examined did not pay the fee the liability would fall upon the ratepayers. We have no doubt that it would, but the solicitude of the police on behalf of the pockets of the public seems here superfluous. The rate would, we conceive, hardly have to be materially increased even if a large proportion of the drunk and disorderly persons charged in the district insisted upon seeing a medical man. That any large number of them should so insist seems improbable, seeing that it would always be possible to inflict a heavier penalty upon the prisoner who had perversely and out of pure malice chosen to give unnecessary trouble, and we are not without a suspicion that it is the anxiety to avoid extra trouble rather than the dread of falling into extravagance that has caused the restriction to be imposed to which we have called attention. The dangers and hardships arising out of such a restriction fall exclusively upon innocent persons. We confess that we have no great confidence in the diagnosis of a policeman, be he constable, sergeant, or inspector. We do not blame him for it; his education is not gained in a hospital, and an additional difficulty is thrown in his way by the charity of the man in the street whose first impulse is to administer a stimulant to anyone suddenly afflicted with illness. A person who faints in public may, even though he be a teetotaler, have spirits poured down his throat and spilled over him until he reeks of them. Then he comes into the hands of those who arrive at their conclusions by the simple process of following their noses. They may be right in nine cases out of ten, but in the tenth case the person may die in a police-cell from want of proper attention.

MALARIAL FEVER AT TÁI PÓ NEW TERRITORY, HONG-KONG.

IN November, 1900, His Excellency the Governor of Hong-Kong instructed two medical officers, Dr. T. M. Young and Dr. J. C. Thomson of the Hong-Kong Medical Civil Service, to make an inquiry into the marked prevalence of malarial fever at Tái Pó, New Territory. The report of these officers to Mr. John Bell, acting principal civil medical officer, has been published as a Government notification from the Colonial Secretary's office, Hong-Kong, and bears date Dec. 6th, 1900. From Sept. 4th to Nov. 12th, 1900, there were caught 309 mosquitoes, of which 40 per cent. were anopheletes and 60 per cent. were culices. On Nov. 12th, the day of their arrival, however, the proportions of anopheletes caught had arisen to 60 per cent. But while during October there were 17 cases of fever occurring among the police there was only one in November up to the 15th. Dr. Young and Dr. Thomson attribute the fall in the number of cases which occurred during this period, which coincides with the second rice harvest, to the "adoption of vigorous prophylactic medication with quinine on two days successively at intervals of seven days." A search was made for the larvæ of anopheles, and these larvæ were found abundantly in the narrow ditches around the upper paddy fields and also in a sluggish stream into which the paddy fields drained. Ten children were brought from the nearest village to the police station who willingly yielded drops of blood at the rate of five cents per drop. In 50 per cent. of these the malaria parasite was found, two cases being of a benign type and three malignant, while all five children proved infective to anopheles feeding upon them. With regard to prophylaxis Dr. Young and Dr. Thomson have no alternative but to recommend "the acquirement and reclamation or efficient drainage of all the paddy fields within a radius of 250 yards from the foot of the hills on which the houses (of the police station) stand." Permanent buildings should also replace the mat-sheds at present used by the civil staff. The buildings should be two storeys high, residential quarters to be only on the upper floor, and the site suggested for these buildings is an island about 900 yards east of the present police station.

A MODIFICATION OF FLECHSIG'S METHOD IN THE TREATMENT OF EPILEPSY.

Dr. E. Meyer and Dr. C. Wickel have contributed an article on the above subject to a recent number of the *Berliner Klinische Wochenschrift* (No. 48, 1900). The work was carried out at the Psychiatric Klinik of Tübingen under Professor Siemerling, with a view to find, if possible, a more satisfactory treatment for cases of epilepsy than the method lately proposed by Flechsig. The plan of Dr. Meyer and Dr. Wickel is to begin the treatment with opium alone, commencing with small doses—e.g., five centigrammes three times a day, which are gradually increased until in about six or seven weeks the dose is nine centigrammes. This maximum dose is given only for one day, after which a bromide mixture is substituted for it—viz., potassium bromide one part, sodium and ammonium bromides each one part, the dose of the mixture being six grammes. The doses of the bromide mixture are now steadily increased till in a week they reach nine grammes per dose. This amount is the maximum dose, and it is continued for a long time and until definite improvement occurs. Under this method of treatment it is necessary that the digestive functions and the functions of the skin should be carefully regulated. Thus, during the opium treatment the patient should have cold baths of short duration (10 minutes) daily at a temperature of 24° C. After a day or two the temperature of the bath should be lowered 1° and the duration of the bathing limited to nine minutes, the next day the duration of the bath being eight minutes and the temperature 22° C. This process should be continued for a week. When the bromide treatment begins the temperature of the bath and its duration should be the same as at the commencement of the opium treatment. Diet should be carefully regulated so as to be light and easily digestible, all nitrogenous foods or beverages, such as beef, coffee and tea, meat broths (which generally contain nitrogenous extractives), acids, sauces, and the like, being avoided or reduced to a minimum. Clinical histories are given by the authors of several cases (10 in all) in which the above lines of treatment were carried out for long periods of

time with the result that the convulsive attacks were diminished in frequency and the patients were maintained in a condition of good health, both mentally and bodily. The gradual increase of the dosage of opium, followed by the administration of the bromide mixture, together with a systematic regulation of baths and diet, constitute the essentials of the new treatment.

THE PLAGUE IN SYDNEY.

DR. J. ASHBURTON THOMPSON, President of the Board of Health of New South Wales, has sent in an official report on the recent outbreak of bubonic plague in Sydney. The report is a voluminous and complete one, including clinical, pathological, and bacteriological records by Dr. A. E. Salter, in charge of the Maritime Quarantine Hospital, and Dr. F. Tidswell, the principal assistant medical officer of the Government. Between Jan. 19th and August 9th, 1900, 303 persons were attacked with the disease, of which number 262 were available for clinical observation. The metropolitan area alone was affected, its population being estimated at 436,000, including about 4000 Chinese and a few coloured people. Among the whites 293 cases occurred and 10 among the Chinese. The disease attacked four times as many males as females. The deaths numbered 103. More than half of the cases occurred between the ages of 15 and 35 years. Cases occurred in all parts of the metropolitan district. Haffkine's prophylactic serum was injected into 10,700 people, and among those thus inoculated 13 suffered from plague but recovered after mild attacks. The Yersin-Roux serum became available on May 13th, but its use did not interfere with the natural course of the epidemic. The opinion provisionally formed was that the serum had antitoxic powers, but in its present state could not be relied on as an active curative agent. The infection had its full virulence at the beginning of the epidemic. The only change noticed was an enfeeblement which began about May 1st. It took seven weeks to furnish the first 100 cases, four weeks to furnish the second 100 cases, and 13 weeks elapsed before the 303rd case was recorded. Dr. Thompson discusses the mode of infection in some detail, and deduces the following conclusions from his study of the epidemic:—1. The disease was not directly communicated from the sick to the well—in other words, was not catching. 2. It was not communicated in any important degree, at all events, from the sick to the well by mediate channels (clothes, household goods, merchandise, excreta). 3. The infection attached to localities and spread to others adjoining and continuous with that in which it was first manifested. 4. It also spread in a fashion which betokened the possibility of its being transported mechanically from an existent focus to a considerable distance and there, in its new situation, initiating an independent focus. 5. In the buildings in any infected locality cases occurred irregularly and showed no special proneness to occur in adjoining houses. 6. When the occurrence of one case among the inhabitants of a building showed that the infection was present in it secondary cases rarely followed. Irregularity of incidence on houses was accompanied with irregularity of incidence on the inmates. 7. An epizootic disease among rats preceded the first case which occurred in man. 8. This epizootic disease was plague. 9. The area over which the epizootic extended was practically co-extensive with that on which cases of plague in man were observed. 10. The epizootic died out as far as can be learned at the same time as the epidemic ceased. 11. The epidemic was caused by communication of the infection from rats to man. On the question of prevention Dr. Thompson says: "The best protection against epidemic plague lies in sufficient sanitary laws, persistently and faithfully executed by local authorities during the absence of disease, and that no other general scheme of defence is practicable." He, however, lays great stress on the importance of securing immunity from rats. The best possible way to gain this result is, as far as possible, to prevent the landing of rats from vessels, and to build houses in such a way and to keep premises in such a cleanly condition as to make it difficult for rats, in the first place, to enter and, in the second place, to live if they do enter.

FRIEDRICH NIETZSCHE: A STUDY IN MENTAL PATHOLOGY.

THE recent death of Nietzsche has been followed by the usual notices and appreciations of his life and work which nowadays mark the close of every brilliant career in literature or philosophy. Dr. W. W. Ireland, in the January number of the *Journal of Mental Science*, deals with the life and writings of the philosopher in a critical spirit, seeking to trace the sources from which sprang many of the extraordinary doctrines and precepts inculcated by Nietzsche. It is shown that a disposition to insanity had been inherited for several generations both on his father's side and on that of his mother. In boyhood Nietzsche was fond of solitude, shunning other children, and was "nice" in his habits. His ways were pious and studious, and he disliked the noisy drinking and smoking habits of the students at the Universities of Bonn and Leipsic where he studied. He manifested great ability, and at the age of 25 years he was appointed Professor of Pathology at the University of Basle. He had musical tastes, was a friend of Wagner, and had a keen appreciation of poetry. When the war of 1870 broke out Nietzsche, then a young man of 26 years, served in the ambulance corps, but contracted diphtheria and enteritis and was invalided home. He never thereafter quite recovered his health and was a martyr to migraine. "He used to suffer every two or three weeks from attacks of migraine, sickness, narrowing of the field of vision, and sleeplessness, often accompanied by mental distress." In the summer of 1875, after an unusual time of suffering, he wrote to a female friend: "Such as we (you and I) never suffer in the body alone; all is intergrown with mental crises." In 1876 Nietzsche got a year's leave to recruit his health, but his illness did not forsake him, and in the beginning of 1879 he resigned his professorship and retired on a pension. After this he led a wandering life, chiefly in Switzerland and Italy. His illness became worse and he suffered from much mental distress as his eyesight was also failing him so that he had to give up reading. During the period of enforced abstinence from reading he relates how "the undermost self, once smothered and stilled by continuous reading, now slowly awakened, bashfully, doubtfully, and at last spoke again, ... and this 'return to myself' was the highest kind of recovery." His physical health now began to improve and he began to write. He devoted his thoughts to philosophy, eschewed the religious faith in which he had been brought up, and inclined at first to Schopenhauer. His attitude soon after became more independent, even belligerent. "My mode of thought," wrote he, "requires a warlike mind, a desire to give pain, a pleasure in saying No." He attacked and denounced the besetting weaknesses of the day. He compared himself to a flame: "I glow and consume myself; light is all that I produce, blackened ashes all I leave." Nordau, analysing Nietzsche's writings and style, says that his language is like that of a madman with flashing eyes, wild gestures, and foaming mouth, and proceeds to show its resemblance to "writings of a similar order of thought and diction" emanating from the insane, a denunciation which is too sweeping. His attitude towards marriage was cold, "he had no idea of the sweet sympathy of a loving wife beyond

mere friendship and conversation," and could not be induced to marry. He had little belief in inborn genius, holding rather that diligent work and culture were the main factors. But his later writings were incoherent, even raving. He called himself "the Godless" and "the Immoralist." His chief commandment was "Be hard, suppress Pity." Eventually Nietzsche grew insane, the first attack being in 1888, and he died in 1900 after 11 years of insanity.

MR. D. HARVEY ATTFIELD, M.A., M.B., B.C., D.P.H. Cantab., has been appointed by the unanimous vote of the International Sanitary Council in Egypt, Medical Director of the Maritime Sanitary and Quarantine Service at Suez. The chief duty is to inspect medically, with the aid of three medical officers of health of different nationalities, all vessels before they enter the canal *en route* for Europe. The attached sanatorium is on the opposite side of the Gulf of Suez at Moses Wells. The sanitary inspection of the pilgrims from Mecca and Medina is carried on during a four-day detention in camp at Tor some 150 miles lower down the gulf. Dr. Harvey Attfield, who was medical officer of health of Watford from 1898 to 1900, filled one of the three junior positions in the Egyptian Quarantine Service from 1894 to 1897. It is not often that an Englishman gets an unanimous vote for an appointment from an international authority in Egypt.

AT the beginning of this year an infectious diseases isolation hospital and a crematorium were opened at Hull. On Jan. 10th the steamer *Friary* arrived from Alexandria with one member of her crew dead. His body was removed to the mortuary and afterwards buried. On Jan. 12th two of the crew sickened and their illness was diagnosed as influenza with pulmonary complications. On Jan 15th, two more sickened, and all four have died. A bacteriological examination made by Dr. E. Klein revealed the presence of plague bacilli, the disease having taken the pneumonic form. The bodies of the four men who died have been cremated. Other cases followed, and up to Jan. 23rd there were five cases under treatment and 10 under observation. One of the latest admissions is a medical man who attended the first cases on the *Friary*.

AT the commencement of the meeting of the Royal Medical and Chirurgical Society on Tuesday evening last, Jan. 22nd, the President, Dr. F. W. Pavy, rose in the chair and spoke as follows:—

"An event has happened within the last two or three hours which has cast sadness and grief into the minds of all. The Queen, the patron of this society, has been taken from us. I am sure that the feelings of all present will dictate the only course which is open to us under the circumstances. We cannot enter with any heart into the proceedings of an ordinary meeting. I therefore propose that this meeting be adjourned."

The motion was carried in silence. The council of the society have resolved "that all the business of the society shall be postponed until after the funeral of Her late Majesty."

THERE will be a discussion on the Feeding of Infants in Health and Disease at a meeting of the West London Medico-Chirurgical Society to be held on Friday, Feb. 1st, at 8.30 P.M. The society's rooms are in the West London Hospital, Hammersmith-road W. Members of the medical profession who are interested in the subject are invited to attend and to join in the discussion.

AT a meeting of the Metropolitan Hospital Sunday Fund held at the Mansion House under the presidency of the Lord Mayor on Jan. 18th the members were occupied with the transaction of formal business, chiefly the appointment of committees and the filling up of vacancies. Since that meeting a vacancy in the Distribution Committee has been occasioned by the lamented death of Dr. Sedgwick Saunders, who, though rarely taking part in the public meetings of the Council, did useful work on this most important committee.

THE death is announced of Dr. Walter Myers, B.Sc. Lond., M.B. Camb., who has been engaged at Para in Brazil for the Liverpool School of Tropical Medicine in investigating the causes of yellow fever. Dr. Myers has been a true martyr to science.

THE amount received by the Soldiers' and Sailors' Families Association is now approximately £62,000, which includes the sums sent to the Lord Mayor at the Mansion House.

THE first issue of the *Philadelphia Medical Journal* for the new century contains the unexpected announcement of the retirement of Dr. George M. Gould from the editorial chair.

THE appointment of Mr. William Maclachlan McDonald, medical officer at Montserrat, to the Legislative Council of that Presidency, has been officially approved.

THE ROYAL COMMISSION ON SOUTH AFRICAN HOSPITALS.

THE report of the Royal Commission appointed to consider and report upon the care and treatment of the sick and wounded during the South African campaign was published on Wednesday last. It is a highly interesting document and will require detailed consideration at our hands. The officers of the Royal Army Medical Corps are spoken of by the Commissioners in terms of high praise—a little reservation being made as to the excess of military tone in some of the service hospitals; and we trust that the suggestions of the Commissioners that the service should in several ways be modified so as to be made more attractive to medical men of high scientific and professional attainments will not be allowed to go unheeded. The employment of nurses in the army is strongly recommended, their attentions, though not desirable in venereal cases, being much preferable to those of orderlies in typhoid fever. The section of the report that deals with the care of the sick and wounded in various places during the campaign, in so far as it supplies an answer to or a commentary upon some of the sensational statements that have been published, will be the section to be read with the greatest avidity by the public. It is also the part concerning which we shall have much to say. The blue-book ends with the following conclusion:—

"We have now, to the best of our ability, pointed out in what respects and to what extent complaints with regard to the care of the sick and wounded in the present South African campaign are well founded. We have also called attention to the causes, so far as we can trace them, of any undue suffering by patients during the campaign. And where, in our opinion, mistakes and oversights on the part of the responsible authorities have occurred we have referred to them. We have also stated what steps ought to be taken with a view of remedying the evils we have noticed. Those evils were serious and ought not to be minimised. But in concluding our report we desire to say that in our judgment, reviewing the campaign as a whole, it has not been one where it can properly be said that the medical and hospital arrangements have broken down. There has been nothing in the nature of a scandal with regard to the care of the sick and wounded; no general or widespread neglect of patients or indifference to their suffering. And all witnesses of experience in other wars are practically unanimous in the view that, taking it all in all, in no campaign have the sick and wounded been so well looked after as they have been in this."

The Death of the Queen.

To the inexpressible grief of her subjects Queen Victoria has passed away. The ruler for over 60 years of an inheritance which under her sway became the largest empire the world has ever seen, her life is an integral part of the history of modern civilisation; so that even to give the briefest sketch of its salient points would be far beyond the scope of THE LANCET. We only here desire to record the profound regret of the profession which we strive to represent at the loss of our good and great Queen.

THE LAST ILLNESS OF THE QUEEN.

From information with which we have been favoured we append the following authoritative account of the last illness of the Queen :—

OSBORNE, Jan. 23rd, 1901.

The Queen's health for the past 12 months had been failing, with symptoms mainly of a dyspeptic kind accompanied by impaired general nutrition, periods of insomnia, and later by occasional slight and transitory attacks of aphasia, the latter suggesting that the cerebral vessels had become damaged, although Her Majesty's general arterial system showed remarkably few signs of age.

The constant brain work through a long life of Royal responsibilities, and the Imperial events, domestic sorrows, and anxieties which have crowded into her later years, may no doubt be held in some measure to account for this discrepancy between the cerebral and general vessel nutrition. The thoracic and abdominal organs showed no signs of disease.

The dyspepsia which tended to lower Her Majesty's originally robust constitution was especially marked during her last visit to Balmoral. It was there that the Queen first manifested distinct symptoms of brain fatigue and lost notably in weight.

These symptoms continued at Windsor where in November and December slight aphasic symptoms were first observed, always of an ephemeral kind and unattended by any motor paralysis.

Although it was judged best to continue the negotiations for Her Majesty's proposed visit to the continent in the spring, it was distinctly recognised by her physicians and by those in closest personal attendance upon her that these arrangements were purely provisional, it being particularly desired not to discourage Her Majesty in regard to her own health by suggesting doubts as to the feasibility of the change abroad to which she had been looking forward.

The Queen suffered unusual fatigue from the journey to Osborne on Dec. 18th, showing symptoms of nervous agitation and restlessness which lasted for two days. Her Majesty afterwards improved for a time both in appetite and nerve tone in response to more complete quietude than she had hitherto consented to observe.

A few days before the final illness transient but recurrent symptoms of apathy and somnolence with aphasic indications and increasing feebleness gave great uneasiness to her physician.

On Wednesday, Jan. 16th, the Queen showed increasing symptoms of cerebral exhaustion. By an effort of will, however, Her Majesty would for a time, as it were, command her brain to work and the visitor of a few minutes would fail to observe the signs of cerebral exhaustion.

On Thursday the exhaustion was more marked with considerable drowsiness; and a slight flattening was observed on the right side of the face. From this time the aphasia and facial paresis although incomplete were permanent.

On Friday the Queen was a little brighter, but on Saturday evening, 19th, there was a relapse of the graver symptoms which with remissions continued until the end.

It is important to note that notwithstanding the great bodily weakness and cerebral exhaustion the heart's action was steadily maintained to the last; the pulse at times evincing increased tension, but being always regular and of normal frequency.

The temperature was normal throughout. In the last few hours of life paresis of the pulmonary nerves set in, the heart beating steadily to the end.

Beyond the slight right facial flattening there was never any motor paralysis, and except for the occasional lapses mentioned the mind cannot be said to have been clouded. Within a few minutes of death the Queen recognised the several members of her family.

A BRIEF BIOGRAPHICAL SKETCH.

Her Majesty Queen Victoria was the daughter and only child of Edward, Duke of Kent, fourth son of George III. (whom he predeceased) by his wife the Princess Victoria Mary Louisa of Saxe-Coburg, widow of Charles, Prince of Leiningen. The death of the Princess Charlotte, the only child of George IV., childless, and the subsequent deaths of Frederick Duke of York and of King William IV. without issue, brought Her Majesty to the throne as heiress of her uncle when only a few days over 18 years of age. It had been evident for some years what her high destiny would be, and she was educated by her mother, the Duchess of Kent, with a special eye towards her fateful future.

In 1837, on the death of William IV., she ascended the throne. The times were critical, as all know. A great Reform Bill had just become law and pleased nobody, for while it curtailed the privileges of the landowners it did not seem to be sufficiently sweeping to benefit the working man. An iniquitous measure prohibited the introduction into the land of foreign corn until wheat had reached the astounding price of 80*s*. a quarter, and it is not too much to say that in 1837 the poor of the land were kept by law at the verge of starvation. Chartism, a movement which aimed at drastic changes in the Constitution, had assumed proportions indistinguishable from rebellion. At this juncture a girl in her teens, sufficiently well grounded in public affairs to understand the enormous responsibilities that fate was placing upon her, was

QUEEN VICTORIA.

called to the head of the State, and came unfalteringly. From the first Council over which she presided the Queen gave evidence of courage, devotion to duty, and an intention to understand the rights and the wrongs of all great questions arising in her realm. She did not, most happily for her, remain long without a confidant to share her tremendous responsibilities. Three years after her accession, that is, in 1840, she married her cousin, His Royal Highness F. Albert A. C. E. Prince of Saxe-Coburg and Gotha and Duke of Saxony. By him she had nine children, of whom the eldest son now succeeds as King Edward VII. In 1861 the Prince Consort died, to the irreparable grief of his widow, who during the next 10 years remained in seclusion as far as devotion to the affairs of the nation would allow her to do so. For 20 years of wedded life the Queen enjoyed the support of a lover and husband who was also a wise and faithful friend, and no one can doubt that the deep affection which she had for the Prince Consort and the unbounded confidence which she rightly placed in his judgment greatly lightened the burden of State affairs for her. Throughout the dark days of the Crimean war, and the still more terrible season of the Indian mutiny, the Queen had her husband beside her to share her grief and confirm her resolution. It is no wonder that the death of such a consort should have remained with her as an ever-abiding sense of loss.

The Queen emerged from the semi-seclusion of her mourning under circumstances which ensured her the sympathy of a people who were loyal to her and cognisant of her many deep claims upon their respect and admiration, but who had at the time not the intimate knowledge of her which it has since been their privilege to obtain. In 1872 the Prince of Wales recovered from typhoid fever after passing through a stage of the disease during which medical opinion held out but small hope of the fortunate issue. The Queen returned public thanksgiving in St. Paul's Cathedral for the recovery of her son and from that time forward lived much more in the sight of her people.

How far the personal history of our dead Queen is also the constitutional history of her people cannot be even guessed at, but when the scientific historians of the future come to tell the history of the reign of Queen Victoria we are certain that the present estimate of her as a wise monarch will be completely justified. She came to the throne the child of kings who were only deterred from exercising their absolutism by a recollection of the fate of the House of Stuart. Fortunate in her early advisers she determined to take a part at once in her own Councils when the thought of her responsibilities might well have appalled her. Happy, extraordinarily happy, in the choice of a husband she was able almost from the first to share these responsibilities with a good man. And so it was that doubly fortified against timidity and strong in the knowledge that she possessed a well-informed mind, a mind open equally to the principles of justice and the sentiments of mercy, Queen Victoria was able to maintain the best parts of her prerogative and to yield without any sense of weakness claims that might have been universally acknowledged as due to the Crown in the seventeenth century, which the Crown had to struggle for in the eighteenth century, and which the educated nation of Great Britain would never for one moment have granted in the nineteenth century. As decade after decade went by under her firm and gentle rule the nation became permeated with the sense that they were governed by a woman not only of wide personal sympathies and of a sweet and religious nature but also of extraordinary mental endowments. They saw that instinctively she ruled upon right evolutionary principles, not seeking for novelty or blindly wedded to the tradition of an ancient *régime*, but taking for her scheme what was good in the past and adding to it what was of promise in the future.

She was prompt to recognise her true position and to realise both its possibilities and its limitations. There can be no doubt that our nation would never have enjoyed its extraordinary era of prosperity beneath a monarch content to rule in name only and willing, because certain attributes of mediæval royalty had to be surrendered, to waive all personal responsibility and to sit behind her Councils a figure-head, the nominal fount of honour and nothing more. The Queen was no less judicious in the assertion of her personality than she was just in her sense of what was due to the progress of the nation committed to her charge, and as a consequence her people as they came to know her loved her. The increasing affection in which the Queen was held underwent remarkable demonstration in 1887 upon the occasion of the Jubilee of her reign, from which time forward, as we have said elsewhere, personal love for the sovereign became a quality common to the whole nation.

To medicine the Queen was always a good friend. She chose her medical advisers with discrimination and honoured with her deep personal friendship more than one of them. During her reign the enormous developments of science have been freely recognised as one of the great factors in British progress, and in no branch of science has more progress been made than in those departments of medicine where the introduction of the use of anæsthetics and the discoveries of the antiseptic treatment are available. Her Majesty showed her appreciation of our profession by the admirable selections which she made of her physicians and surgeons, and by the faith which she put in their advice. It is noteworthy that the Queen was early inducted into orthodox medicine, for she was the first member of our Royal Family to be vaccinated.

There were until shortly before the commencement of her fatal illness few premonitory signs of real danger to her life. To the grave public anxieties and private griefs of the last 18 months of her reign her death may possibly be attributable in a secondary degree, but the end came as a peaceful and natural conclusion of a long, full, and beautiful life. Her Majesty died at half-past six o'clock in the afternoon of Tuesday, Jan. 22nd, in the eighty-second year of her age, the immediate cause of death being cerebral failure. The authoritative statement which we publish above tells the story of the last illness so clearly to the medical man, that we need not enlarge upon it.

THE REPORT OF THE ANÆSTHETICS COMMITTEE OF THE BRITISH MEDICAL ASSOCIATION.

IN consequence of a resolution unanimously adopted by the Section of Therapeutics at the annual meeting of the British Medical Association held in Bournemouth in 1891, a committee was appointed "to investigate the clinical evidence with regard to the effects of anæsthetics upon the human subject; and especially the relative safety of the various anæsthetics, the best methods of administering them, and the best methods of restoring a patient in case of threatened death." From the general committee an Analysis Sub-committee was formed, and we have now in a bulky volume of 134 pages the report of this Analysis Sub-committee. The committee instituted an inquiry, which extended over the year 1892, into all cases of the administration of anæsthetics in the United Kingdom of which accurate notes could be obtained. Records were derived from personal observation in hospital or in private practice or both during the year 1892 (1) in cases where no dangerous symptoms have occurred and (2) giving special details of cases in which dangerous symptoms or death occurred.

A list is given of the sources from which reports of cases were returned in the record books, together with the names of the observers, and in all 136 books were returned, recording details of 25,920 cases. Professor W. Ramsay, Professor of Chemistry in University College, London, publishes a report upon samples of the anæsthetics employed in cases which displayed dangerous symptoms, and Lieutenant-Colonel E. Lawrie, I.M.S., of Hyderabad, sends a report containing a summary of 1521 administrations of chloroform in India.

The Analysis Sub-committee give the fullest details in reference to uncomplicated and complicated cases, cases with minor complications, cases of anxiety, cases of danger, and cases of death. In the table of anæsthetics employed there were, out of a total of 25,920 cases analysed, 13,393 in which chloroform was the anæsthetic employed, 4595 of ether administration, 2911 of nitrous oxide, 2071 of gas and ether, 678 of A.C.E. mixture, 597 of nitrous oxide mixed with oxygen, 418 of chloroform and ether in various proportions, 275 of chloroform followed by A.C.E. or by some similar mixture, and 155 of A.C.E. followed by ether.

The uncomplicated cases amounted to 25,163, or 97·169 per cent. of the total cases in the record books, while the complicated cases (those presenting unusual symptoms or sequelæ referable wholly or in part to the anæsthetic) were 733 in number, being 2·831 per cent. of the total cases in the record books. The complicated cases are sub-divided into cases with minor complications (some abnormality but no actual anxiety or danger), cases of anxiety (with symptoms requiring remedial measures but not involving immediate danger), cases of danger (with symptoms threatening the patient's life), and cases of death (due wholly or in part to the anæsthetic). The most elaborate abstracts are given of cases falling into each of these subdivisions, with the anæsthetic employed in each case.

29 cases of death due partly or entirely to the anæsthetic are considered, and details of all these cases are appended. The influence of various factors upon the phenomena of anæsthesia is most carefully discussed, and it is curious to note that the percentage of complicated cases was greater in males than in females, as well as the percentage of danger cases. In males the percentage of danger cases under chloroform was nearly six times that of danger cases under ether, more than seven times that of danger cases under gas and ether, and nearly two and a half times that of danger cases under the A.C.E. mixture. In the female cases the percentage of danger cases under chloroform was nearly twice that of danger cases under ether, more than twice that of danger cases under gas and ether, and nearly twice that of cases under the A.C.E. mixture. Minor complications are notably more frequent in males than in females under ether. The frequency with which cases of danger occurred in patients in good condition was as follows: with chloroform, one in every 133 administrations; with ether, one in every 654 administrations; and with gas and ether, one in every 834 administrations.

Much information is given as to the influence of various anæsthetics in certain pathological states, while an interesting comparison is given of the methods of their administration. In giving chloroform the towel method shows the highest percentage of complications and the highest danger rates; the method of giving the drug on lint shows a striking diminution in both the complication and danger rates.

Of the 29 deaths recorded 18 were under chloroform. Of these three are considered to have been due entirely to the anæsthetic and four to the anæsthetic principally and the patient's condition secondarily; in the others there is either doubt as to the relative shares taken by the three factors—anæsthetic, patient's condition, and operation; or the death was distinctly due more to one or both of the two latter causes than to the anæsthetic. Of the deaths under ether not one is held to be due entirely to the anæsthetic. The conclusion is emphasised that danger to life under the use of chloroform is greater than when other anæsthetics are employed. We have drawn attention in mere outline to this report which teems with the most valuable information on almost every phase of the administration of anæsthetics. The following are the conclusions which the sub-committee think appear to be justified as a result of their most exhaustive study and analysis of the whole cases:—

CONCLUSIONS.

Relative safety of the various anæsthetics.—1. The relative safety of the various anæsthetics may be gathered from the statistical tables in the report. When only those cases of danger which were held to be due entirely to the anæsthetic are considered the following instructive figures are obtained, further emphasising the danger of chloroform as contrasted with ether. Cases of danger (including deaths) considered to be due entirely to the anæsthetic: under chloroform, 78, giving a danger rate of 0·582 per cent.; under the A.C.E. mixture, 1, giving a danger rate of 0·147 per cent.; under mixtures of chloroform and ether, 2, giving a danger rate of 0·478 per cent.; under the A.C.E. mixture followed by chloroform, 1, giving a danger rate of 1·694 per cent.; under chloroform preceded by ether, 5, giving a danger-rate of 2·2 per cent.; under chloroform followed by mixtures of alcohol, chloroform, and ether, 1, giving a danger-rate of 0·36 per cent.; under ether, 2, giving a danger-rate of 0·065 per cent.; under "gas and ether," 3, giving a danger-rate of 0·096 per cent.; under ether preceded by chloroform, 1, giving a danger-rate of 0·480 per cent.; under ether preceded by the A.C.E. mixture, 0; under the chloroform group of anæsthetics (addition of the first six headings above), 88, giving a danger-rate of 0·584 per cent.; and under the ether group of anæsthetics (addition of the last four headings above), 6, giving a danger-rate of 0·085 per cent. 2. Although (excluding nitrous oxide) ether may be accepted as the safest routine agent certain circumstances determined by the state of the patient, the nature of the operation, &c., may render the use of some other anæsthetic or combination of anæsthetics both safer and easier.

The best methods of administration.—3. No method of administration of chloroform is free from danger, but an examination of the complicated cases appears to show that the occurrence of danger depends largely upon the administrator who employs any particular method. 4. No conclusion from the evidence before the committee as to the best method of administration of ether and "gas and ether" is possible. 5. The data warrant the conclusion that the A.C.E. mixture should not be given from a closed inhaler—e.g., Clover's. This conclusion applies to all mixtures containing chloroform.

Best methods of restoration.—7. The sub-committee are unable from the material at their disposal to draw any conclusion upon this point.

Clinical evidence regarding anæsthetics generally.—8. Anæsthetics are more commonly associated with complications and dangers in males than in females. 9. Excluding infancy, and taking anæsthetics collectively, the complications and dangers of anæsthesia increase *pari passu* with advancing age. 10. Anæsthetics are notably more dangerous in proportion as the gravity of the patient's state increases. 11. Danger to life is especially likely to be incurred at early periods of the administration of anæsthetics, while the tendency to less grave complications increases directly with the duration of anæsthesia. 12. The tendency for complications, dangerous and otherwise, to occur increases *pari passu* with the gravity of the operation.

Clinical evidence regarding chloroform.—13. Chloroform is about twice as dangerous in males as in females. 14. Chloroform is most dangerous during early infancy and after 30 years of age; least so from 10 to 30 years of age. 15. In conditions of good health chloroform is very much more dangerous that other anæsthetics. In grave conditions chloroform still remains the least safe anæsthetic, but the disparity between it and other anæsthetics is far less marked than in health. 16. When danger occurs under chloroform, whatever its exact nature may be, there is abundant evidence that in a large proportion of cases the symptoms that are observed are those of primary circulatory failure. 17. Imperfect anæsthesia is the cause of a large number of cases of danger under chloroform. 18. Vomiting during anæsthesia, which may lead to danger, seems to be more frequent under chloroform than under other anæsthetics. 19. Struggling is very much more frequent in the complicated cases under chloroform than in the uncomplicated, and this phenomenon must therefore be regarded as a source of grave danger under chloroform. 20. The tendency for circulatory complications to appear increases directly with the relative amount of chloroform in the anæsthetic employed. 21. While vomiting is more common after administrations of ether, severe and prolonged vomiting is more common when chloroform has been used. 22. Circulatory depression following anæsthetics is more common after chloroform than after ether. 23. While the respiratory complications of anæsthesia as a whole are of equal frequency under the ether and chloroform groups respectively, yet those that occur under ether are mostly of a trifling and transitory

nature while those that occur under chloroform are more grave and persistent.

Clinical evidence regarding ether.—24. Under ether the complications of anæsthesia are more frequent with males than with females, but with the former they are generally slight, ether being rather more dangerous with females than with males. 25. Ether, where employed throughout or preceded by nitrous oxide gas or by the A.C.E. mixture, is singularly free from danger in healthy patients. 26. Minor troubles in administration due to laryngeal irritation and increased secretion are more common under ether and "gas and ether" than under chloroform and its mixtures. 27. Struggling occurs more frequently with ether when given alone than with other anæsthetics, but it rarely leads to danger. 28. After-vomiting is more common with ether than with other anæsthetics, but it is usually transient. 29. Bronchitis is much more common as an after-effect of ether than of chloroform. 30. With "gas and ether," as with ether, dangers are more common in females, although complications are more frequent in males.

Clinical evidence regarding mixtures and successions of anæsthetics.—31. The A.C.E. mixture in most of the statistical tables holds an intermediate position between chloroform and ether. 32. The A.C.E. mixture is more dangerous in males than in females, but not to such a marked degree as is chloroform. 33. The administration of ether antecedent to chloroform does not abolish the possibility of chloroform dangers. 34. The various mixtures and successions of anæsthetics were recorded too infrequently to justify definite conclusions.

General conclusion.—35. From the evidence before the sub-committee they are convinced that by far the most important factor in the safe administration of anæsthetics is the experience which has been acquired by the administrator. In many cases the anæsthetisation completely transcends the operation in gravity and importance, and to insure success, particularly in these cases, it is absolutely essential that an anæsthetist of large experience should conduct the administration.

THE WAR IN SOUTH AFRICA.

THE public mind has of late been occupied with one absorbing subject—the condition of the Queen. Nothing else seemed worthy of consideration, and in point of fact nothing else received consideration. People have been living in a state of suspense and nervous tension and in an alternation of hopes and fears, and even where, as in the case of the medical profession, fears and forebodings as to what the issue would be formed the dominating feeling in their minds, they as an involuntary instinct and impulse of their being nevertheless strove to nurture hope in their hearts as long as it was possible to do so. The news that the invading Boers in Cape Colony were nearing the coast, in the all-pervading sorrow and gloom caused by the illness and death of Her Majesty, received very little attention.

The war in South Africa has from the first been unique and the situation at present is probably in some respects without precedent. The Boers are displaying an uncommon degree of renewed energy and the position of affairs in South Africa is not such as the nation might have expected after having been assured that the war was over and after having read in the papers of the return of troops to this country and the colonies.

But the Boers, despite of all the difficulties and embarrassments they can create in the meantime, cannot live for ever by looting. They cannot obtain unlimited supplies of food, ammunition, war material, and horses, they must provide for the care of their sick and wounded, and the further they get from the sources of their supplies the more difficult will their task become. Moreover, when reinforcements in the shape of mounted troops reach Lord Kitchener the conditions will have changed. In the meantime there is great activity at the Cape in recruiting for local corps and volunteers.

Speaking of the number of officers who from one cause and another have left the seat of war for this country we may say that the officers who have been most overworked and are in most need of rest are the medical officers, but they, owing to their limited numbers, are compelled to stick to their duties in the field. A glance at the casualty returns shows that enteric fever is still very prevalent among the British forces in South Africa. This disease, together with dysentery, make up the bulk of the sickness. There has, too, been a good deal of desultory fighting of one sort and another owing to the marauding attacks of the Boers and as a consequence there has been an accession to some extent to the list of wounded in hospital.

INFECTIOUS DISEASES AT SWINDON.—At the quarterly meeting of the board of the Swindon and District Hospital held on Jan. 17th it was reported that there were 42 infectious cases in the hospital, being 20 more than the institution was provided for. It was decided to remove some of the convalescent cases to the new small-pox hospital.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6858 births and 4320 deaths were registered during the week ending Jan. 19th. The annual rate of mortality in these towns, which had been 16 9, 17·5, and 19·6 per 1000 in the three preceding weeks, declined again last week to 19·1. In London the death-rate was 18·7 per 1000, while it averaged 19·4 in the 32 large provincial towns. The lowest death-rates in these towns were 13·9 in Croydon, 14·1 in Cardiff, 14·7 in Oldham, and 14·9 in West Ham; the highest rates were 23·3 in Swansea, 23·4 in Liverpool, 24·7 in Preston, and 24·8 in Sunderland. The 4320 deaths in these towns included 374 which were referred to the principal zymotic diseases, against 323 and 389 in the two preceding weeks; of these 99 resulted from whooping-cough, 95 from diphtheria, 79 from measles, 38 from "fever" (principally enteric), 36 from diarrhœal diseases, and 27 from scarlet fever. The lowest death-rates last week from these diseases occurred in Portsmouth, Oldham, Huddersfield, and Halifax, and the highest rates in Nottingham, Bolton, Blackburn, Preston, and Sheffield. The greatest mortality from measles occurred in Swansea and in Wolverhampton; from scarlet fever in Preston; from whooping-cough in Nottingham, Birkenhead, Preston, and Sunderland; and from diarrhœal diseases in Blackburn. The mortality from "fever" showed no marked excess in any of the large towns. The 95 deaths from diphtheria in the 33 towns included 32 in London, 13 in Sheffield, six in Leeds, six in Bristol, and five in Birmingham. No fatal case of small-pox was registered last week either in London or in any of the 32 large provincial towns, and no case of small-pox remained under treatment on Saturday, Jan 19th, in any of the Metropolitan Asylums Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2171, against 2535, 2390, and 2277 on the three preceding Saturdays; 187 new cases were admitted during the week, against 167, 163, and 156 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had increased from 306 to 392 in the four preceding weeks, further rose last week to 422, but were 238 below the corrected average. Influenza was certified as the primary cause of 20 deaths in London last week, against 10 in each of the two preceding weeks. The causes of 59, or 1·4 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Portsmouth, Bristol, Cardiff, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Norwich, Liverpool, Sheffield, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·2 and 21·9 per 1000 in the two preceding weeks, further rose to 24·0 per 1000 during the week ending Jan. 19th, and showed an excess of 4·9 per 1000 over the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 15·0 in Leith and 15·5 in Greenock to 28·6 in Perth and 29·3 in Aberdeen. The 752 deaths in these towns included 61 which were referred to whooping-cough, 23 to measles, 16 to diarrhœa, 14 to "fever," six to diphtheria, three to small-pox, and two to scarlet fever. In all, 125 deaths resulted from these principal zymotic diseases, against 76 and 101 in the two preceding weeks. These 125 deaths were equal to an annual rate of 4·0 per 1000, which was 2·3 per 1000 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping-cough, which had been 29 and 49 in the two preceding weeks, further rose last week to 61, of which 44 occurred in Glasgow, 10 in Dundee, and five in Edinburgh. The deaths from measles, which had been 15 and 12 in the two preceding weeks, rose again to 23 last week, and included nine in Aberdeen, eight in Edinburgh, and three in Leith. The fatal cases of diarrhœa, which had increased from 10 to 22 in the five preceding weeks, declined again last week to 16, of which seven were registered in Glasgow, four in Dundee, and two in Aberdeen. The deaths referred to different forms of "fever" which had been seven, two, and two in the three preceding weeks, increased

to 14 last week, and included 10 in Glasgow, two in Edinburgh, and two in Aberdeen. The fatal cases of diphtheria, which had been three and eight in the two preceding weeks, declined again last week to six, of which three occurred in Edinburgh. The deaths from small-pox, which had been three, three, and two in the three preceding weeks, rose again last week to three, and were all recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 105 and 123 in the two preceding weeks, further rose last week to 139, but were 59 below the number in the corresponding period of last year. The causes of 30, or nearly 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 29·4 and 28·3 per 1000 in the two preceding weeks, rose again to 30·4 per 1000 during the week ending Jan. 19th. During the past four weeks the death-rate in the city has averaged 27·4 per 1000, the rates during the same period being 18·2 in London and 20·9 in Edinburgh. The 202 deaths belonging to Dublin registered during the week under notice were 14 in excess of the number in the preceding week and included 16 which were referred to the principal zymotic diseases, against 23 and 18 in the two preceding weeks; of these, 12 were referred to whooping-cough, three to "fever," and one to diarrhœa. These 16 deaths were equal to an annual rate of 2·4 per 1000, the zymotic death-rate during the same period being 1·6 in London and 3·0 in Edinburgh. The deaths from whooping-cough, which had been 13 and 10 in the two preceding weeks, rose again last week to 12. The fatal cases of "fever," which had been three in each of the two preceding weeks, were again three last week. The 202 deaths in Dublin last week included 41 of children under one year of age and 51 of persons aged upwards of 60 years; the deaths of infants largely exceeded the number in the preceding week, while those of elderly persons showed a decline. Five inquest cases and five deaths from violence were registered; and 72, or more than a third, of the deaths occurred in public institutions. The causes of 10, or nearly 5 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following officer has been noted for accelerated promotion for services in China:—Surgeon Edward Butler Pickthorn.

The following appointments are notified: — Surgeons: Mowat to the *Duke of Wellington;* J. G. Corry to the *Northampton*, for the *Calliope;* and F. Fedarb to the *Excellent*.

ROYAL ARMY MEDICAL CORPS.

Major J. C. Morgan, R.A.M.C., has been appointed Medical Officer of the Duke of York's Royal Military School, Chelsea, vice Lieutenant-Colonel J. H. C. Whipple, A.M.S. (retired), in recognition of his services as staff surgeon in charge of head-quarters in the Tirah campaign, 1897–98.

DEATHS IN THE SERVICES.

Deputy-Inspector-General Edward Hodges Cree, R.N. (retired), aged 87 years, on Jan. 15th at his residence, 2, Pemberton-gardens, Holloway. At one time he held the post of staff-surgeon at the dockyard at Portsmouth, and was surgeon on board the *Rattlesnake*, the *Vixen*, and the *Fury* during the war with China (medal) and the operations on the coast of Borneo in 1839. He was also surgeon on board the *Odin* in the Baltic in 1854 (medal) and was at the taking of Sebastopol in the following year (medal).

THE PRINCESS AND THE WOUNDED.

The Princess of Wales has presented the patients at the Gables private military hospital, Surbiton, with handsome pocket-cases, each inscribed "A gift from the Princess of Wales," and a cartridge pencil bearing the name of the engagement at which the recipient was wounded.

DISCHARGED TO DUTY.

The following have been discharged to duty: Civil Surgeons W. R. Kemp, J. P. N. Casey, FitzGibbon, Mackenzie, Hoskin, Petty, and McMurty.

THE WAR IN CHINA.

It is very gratifying to hear such good accounts of the British forces—and of those of the Indian contingent especially—serving in China. The cold is severe there at the present season, but it is not the case that the Indian troops are dying of cold and are not properly cared for. It is inevitable, as the special correspondent of the *Standard* writes, that in every campaign a certain number of deaths should take place from sickness and the total mortality may be large by the time the war is over, but the troops are well provided for and certainly as well as they can be under the circumstances. It must be borne in mind that China is not at all like England in the way of sanitation. Tientsin, for example, is entirely without drainage, even of the most rudimentary kind, and there is a good deal of unavoidable overcrowding, especially among the native population. The *Standard* correspondent says:—

> The British military authorities have managed in some way to get all their men h uses, and have rented some of the best places available. They have secured stocks of coal and an ample supply of stoves; the commissariat stores are full to overflowing, and, so far as most of us can see, nothing has been left undone that could have been done to keep the native troops well and fit. Native sentries have short duty, and are served with hot tea before and after duty. And as for clothing Tommy would smile could he see some of his dusky colleagues going about town. Many officers, almost fastidiously anxious to keep their men sound, give them extra comforts, &c.

The men have plenty of warm clothing of all kinds, but all who know anything of the habits and practices of our Indian native troops, excellent as these troops are in respect of courage and discipline, know that they are singularly "absent-minded" and careless in exposing themselves to all kinds of risks from colds and chills, and that they have to be watched like children in these respects. Native soldiers on field service are peculiarly liable to pneumonia and pulmonary diseases. In spite of their habits and practices, against which the officers fight with energy, the sick list is not a long one. No one, says the correspondent, can suggest the slightest neglect on the part of the military authorities.

COMPLIMENTARY DINNER TO MEDICAL AND SURGICAL OFFICERS OF THE RED CROSS HOSPITAL.

A complimentary dinner to Colonel Cayley and the medical staff of the National Red Cross Hospital was given on Friday evening, Jan. 18th, at Messrs. Ferguson and Forrester's Restaurant, Buchanan-street, Glasgow. The Marquis of Breadalbane, K.G., presided and amongst those present were Professor George Adam Smith, Colonel R. C. Mackenzie Colonel Cayley, commandant of the staff; Mr. H. E. Clark, senior surgeon; Sir David Richmond, Professor Chiene, Sir James Bell, Dr. Bearson, Dr. John Cowan, Dr. John Aitken, Dr. Stirling, and Dr. John M'Intyre.

Correspondence.

"Audi alteram partem."

THE EXAMINATIONS FOR THE SWISS FEDERAL DIPLOMA

To the Editors of THE LANCET

SIRS,—It will be convenient for me and of use to others if you will allow me to describe my experience of the examinations required for the Swiss Federal diploma under the new regulations for I am receiving many letters on the subject, as I am the first Englishman to obtain the diploma under these regulations. It is 10 years since they were enforced, and meanwhile only one Englishman has attempted, and no one has succeeded, in obtaining the diploma.

The examinations required are three in number. 1. The Federal Maturité. 2 The examination in anatomy, physiology, embryology, and history. 3. The "professional," which includes pathology and pathological anatomy, medicine, therapeutics, diseases of children, ophthalmic surgery, surgery, midwifery and gynæcology, hygiene medical jurisprudence, and mental diseases. The examinations are conducted in French German, or Italian. Those candidates who elect to be examined in French or Italian have to go to Geneva or Lausanne Those who choose German must go to Basle, Berne, or Zurich. The examinations are held twice a year, in the spring and in the autumn. Application for admission to, or for information about, the

Maturité should be made to Professor Geiser, Kussnacht, near Zurich. For the medical examinations application should be made to Professor Courvoisier, Holbeinstrasse, Basle. No degree in arts or medicine of any university will gain for any candidate any privileges or exemption. He will have to undergo every part of every examination precisely as the other candidates.

I will deal with the medical examinations first. They are long and very practical and very thorough, divided up into many parts, and are chiefly oral. In the first one there is a "practical" in each subject, followed by 20 minutes to half-an-hour's good heckling. Then a week afterwards there is a solemn oral in each subject. Instead of the "practical" in physiology there may be an essay to write. The subjects offered at the last examination were "The Gases of the Blood," "Vital Capacity," "Pancreatic Secretion and Digestion." Three hours are allowed. In anatomy one is allowed five hours to dissect the parts allotted. A good deal of embryology is required, and microscopic sections have to be drawn and described. In histology specimens have also to be cut, stained, and mounted. In the "professional" there are 23 parts. In medicine, a case in the wards has to be taken very fully and diagnosed; another case is the subject of a *vivâ voce*, and there is also a solemn oral examination. In surgery the arrangement is the same, with the addition of two operations on the cadaver. In obstetrics there are a clinical examination and a practical examination in operations on the mannequin, as well as an oral. In the other subjects there are papers and oral examinations. The whole of the examination takes about a month.

Now as to the "Maturité," which is the great difficulty. It is under the management of the Commission de la Maturité Fédérale, of which Professor Geiser is the President, and is not in any way under the management or influence of the Comité Directeur of Medical Examinations. If a candidate fails twice he cannot enter again. If he passes creditably in some subjects, but fails in others, he is excused from being examined the second time in those subjects in which he has done well. The scheme is as follows:—

A. *Languages.*—1. Latin: Livy, Cicero, Virgil, Horace, Plautus. 2. Greek: Homer and Xenophon; some chapters of Plato and Sophocles. 3. Maternal language: History of the literature; written composition on some literary or scientific subject. 4. A second maternal language (a national Swiss language): Ability to read and translate it; translation and explanation of a classic. 5. Greek may be replaced by English or by a third national Swiss language.

B. *History and Geography.*—Ancient history; history of the middle ages and modern history. Physical and political geography.

C. *Mathematics.*—Algebra: Equations of the second degree; arithmetical and geometrical progression; binomial theory. Geometry: Euclid; rectilinear trigonometry; elementary problems of spherical trigonometry; conic sections.

D. *Natural Sciences.*—The principal types of the animal kingdom and general knowledge of the human body; the organs of the higher plants; the principal families of the natural system; the most important minerals. Physics and chemistry: General properties of matter; mechanics of solids, liquids, and gases; the principal laws of acoustics, of optics, of heat, of electricity and magnetism; the principal chemical elements and their most important combinations.

It will be at once seen how ill-defined are the limits of the scheduled subjects. For the guidance of others I will briefly describe my personal experience. In Latin we had a longish piece of Latin prose, for which we were allowed three hours. Then there is a *vivâ voce* in the set authors. I was given a part of one of Cicero's letters and was much questioned on points of grammar and construction. I took English instead of Greek. We were given a piece of French to put into English, and had to translate a piece of Green's "History of England" *vivâ voce*. I took French as my *langue maternelle*. We were given three hours to write the essay. The subjects from which we could choose one were "The Life and Work of Molière," "A Conversation between a Man of Science and a Man of Letters," "The Comparison of the Classical Drama with the Naturalistic." In the *vivâ voce* I was taken over the Chanson de Roland, Boileau, and Victor Hugo. As my second national language I took Italian. We had a longish piece of Italian prose (i.e., French with Italian) and in the *vivâ* I was given half a page of Manzoni's "I Promessi Sposi." In ancient history I was taken over Rameses II. and his times; Athens and Sparta and the comparison of the codes of Lycurgus and Solon; also the "Code Napoléon." In modern history we discussed Louis XIV. and his later times. There is no written paper in history, but the field is absurdly wide. In geography I was taken over isotherms, isobars, and cyclones and anticyclones. There are no paper. The mathematics are very stiff. There are a paper and a *vivâ voce*. The paper consisted of six problems—two in algebra, two in trigonometry, and two in conics. We might choose *one* in each subject *only*. They were all catchy and difficult. In the *vivâ voce* one is called upon to work sums on a blackboard involving the use of logarithms. I was also taken over the ellipse and parabola.

Natural History.—This is all *vivâ voce*. In zoology I was given the crocodile's heart, and the lungs of snakes, and the classification of fishes. In botany the ovary and the signification of the various forms of placentation took up the 20 minutes. In geology the various forms of crystallisation are required. In physics a good deal is required, much more than is indicated in the programme. I was taken over the comparison of electric, heat, light, and Roentgen rays, mirrors, reflection of sound, and the application of electricity to motors. In chemistry I was given nothing but phosphorus and sulphur to talk about. All this is *vivâ voce*. The examination takes four or five days. There is a different examiner for each subject. In the oral examinations another examiner is always present. Six is the highest given in each subject, and 0 is the lowest. One 1 is enough to plough a candidate or 2 twos or 3 threes. There were seven candidates, and only three of us passed.

I found it necessary to spend three or four months in being coached by professors at Lausanne, for the limits of the subjects of the schedule are so ill-defined and it is so difficult to find suitable text-books and so difficult to know what was required and what not required that "coaching" seemed absolutely necessary. I was treated with the utmost fairness and courtesy throughout, and nothing could exceed the kindness of Professor Fovel of Lausanne, the local president of the Maturité examination, or of Professor Lâskowsky and Professor Jenzer of Geneva. I would only add that no M.D. of any Swiss university gives the right of practising in Switzerland. Only the Federal diploma can do it for the whole of Switzerland and the cantonal diploma in certain cantons.

I am, Sirs, yours faithfully,

Davos, Jan. 10th, 1901. EDWARD H. DOUTY, M.D. Cantab.

PERIPHERAL NEURITIS FROM WHISKY-DRINKING.

To the Editors of THE LANCET.

SIRS,—The most important discovery recently made by Dr. E. S. Reynolds that arsenic was present in the beer taken by a number of patients suffering from peripheral neuritis in Manchester will lead to the reconsideration of the etiology of alcoholic neuritis. There can now be no doubt of the correctness of his conclusions that many persons have recently suffered from toxic symptoms due to the presence of arsenic in beer, and that in many cases the peripheral neuritis has been entirely, or in part, produced by arsenic. Whilst his discovery is one which is of the greatest service to the community, and one of which English medicine may be justly proud, it will also lead to renewed investigations respecting the toxic effects of alcoholic beverages. Whether beer free from arsenic is capable of producing peripheral neuritis, as is generally believed, will be clearly shown by the experience of the next year or two when, in Manchester at least, all beer will be free from arsenic. To all interested in the subject the question will probably occur whether peripheral neuritis is produced by the drinking of spirits and if so whether this neuritis is also the result of arsenic as an impurity in spirits. Whilst it is stated in many text-books that alcoholic neuritis is produced by spirit-drinking it must be admitted that spirit-drinkers are often beer-drinkers also. One remembers cases of peripheral neuritis in which the form of alcohol taken was said to be spirits, but recently I have had the opportunity of observing a case in a whisky-drinker which appears to be worthy of record, since so much attention is now being given to the etiology of various forms of neuritis. The patient was under the care of Dr. Tytler,

surgeon to the Ancoats Hospital, where I examined him and obtained a careful history of the case. There could be no doubt that the case was one of advanced peripheral neuritis. All four limbs were paralysed, the wrists and feet were dropped, the knee-jerks were absent, and muscular hyperæsthesia was marked; the bladder and rectum were not affected. There were no cutaneous affections. Death occurred apparently from paralysis of the diaphragm. I made a microscopical examination of the peripheral nerves and found the changes of advanced parenchymatous peripheral neuritis. The patient had been a billiard-marker at a public-house and had had a free choice of alcoholic beverages. He had a great liking for spirits, but did not like beer. He stated, and persisted in the statement on every examination, that he had drunk freely, but that his drink had been almost exclusively Irish whisky. He maintained that during the whole 12 months previously to the onset of his illness he had not taken more than six pints of beer. I had no reason for doubting this statement, but his relatives were questioned separately; they also declared that his statement was quite true and that he had taken large quantities of whisky, but had not been a beer drinker. I separately questioned his friends at the public-house where he had been employed and they also confirmed his statement.

I obtained three samples of the kind of Irish whisky he had taken and tested them for arsenic, employing Reinsch's test, and performing the test in the same manner as I have recently done in the examination of a number of specimens of beer in which I have detected arsenic. In the samples of Irish whisky I could not detect the slightest evidence of arsenic. In order to determine whether arsenic could be detected in whisky by Reinsch's test I made a control experiment by adding a drop of liquor arsenicalis to whisky. With this control solution Reinsch's test gave a very definite reaction. Being informed that at the onset of his illness the patient had occasionally, but rarely, taken a small amount of port wine, I examined the port wine also for arsenic, but obtained no reaction. This case appears to show clearly, that peripheral neuritis can be caused by the drinking of whisky, and that whisky obtained from the same source as that drunk by the patient gave no reaction for arsenic with Reinsch's test. Whether whisky ever contains arsenic is a question for the analytical chemist to decide. As spirits are now being somewhat freely consumed in place of beer in Manchester and neighbourhood a favourable opportunity will probably exist for making observations on the occurrence of peripheral neuritis and its exact cause amongst spirit-drinkers. If arsenic can be excluded as the cause of peripheral neuritis from whisky drinking, as appears probable from the results of examinations of whisky recently published in THE LANCET and from the examination in the case just mentioned, the question remains to be decided whether the neuritis is due to the alcohol (as is generally believed), to furfural, or to other substances or impurities in the whisky. The answer to this question is of much importance with respect to the etiology of alcoholic neuritis. I am, Sirs, yours faithfully,

Manchester. R. T. WILLIAMSON.

"THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND."

To the Editors of THE LANCET.

SIRS,—I hardly suppose that any member of the College Council will condescend to reply to Dr. Albert Morton's query as to the utility of the annual meeting of Fellows and Members. Writing as one who has attended practically all of these meetings since their institution, I must say that I think the time has come when they should be either abolished or placed on a different footing. I imagine that the meetings were originally promoted owing to a dim feeling on the part of the Council that the College was becoming somewhat out-of-date, not to say fossilised. Except as an examining body no one thought anything about it. The munificence of Sir Erasmus Wilson created the necessity for a new Charter and gave the College the opportunity of a new lease of life upon broader and worthier lines than hitherto. Unfortunately, this opportunity has been missed. The Council established these meetings but had not the courage to effect what was their obvious corollary—the representation of the members. Consequently for years past matters have been at a deadlock. Year after year the farce which Dr. Morton describes is enacted, and latterly the majority of the Council are conspicuous by their absence.

It was for a long time hoped by many that the Council would agree to make the College a more popular professional institution and would place it at the head of all legitimate efforts for improvement and reform. This hope has hitherto been frustrated owing to timidity and want of confidence in the Members. The Council has allowed its mistrust of individuals to interfere with its higher duty towards the body corporate.

Nothing has been done to encourage Members to take an interest in the College. An outside organisation is allowed to practically summon the meetings and to prepare the resolutions. But for this organisation all interest in College affairs would have long ceased. At the last meeting the Council even refused a request to circulate the report beforehand among the Members. Many Members have striven hard to prevent the College from lapsing into its former mediæval and lethargic condition, but the Council has absolute power over its destinies and should this happen upon it will be the blame. I am, Sirs, yours faithfully,

Putney Heath, S.W., Jan. 22nd, 1901. W. G. DICKINSON.

THE CERTIFICATION OF LUNATICS IN POOR-LAW INFIRMARIES.

To the Editors of THE LANCET.

SIRS,—I write on a matter of legal and ethical interest. An alleged lunatic is brought by the police to the infirmary under Section 20 of the Lunacy Act, 1890. Next day the justice visits the infirmary and brings with him a medical man to examine my patient. This gentleman certifies for removal to an asylum. My longer knowledge of the case leads me to consider that it would be better to detain the patient in the infirmary for further observation. I admit that under Section 16 of the Lunacy Act the justice "shall call in *a* medical practitioner"—i.e., any "doctor" he chooses; but I submit that to pass over the usual medical attendant or surgeon under whose immediate care the patient is and to call in an outside man is contrary to the spirit, if not the letter, of the Lunacy Act. For does not Section 31, dealing with cases in which two medical certificates are required, specially enjoin that "whenever practicable" one "*shall*" "be under the hand of the usual medical attendant, if any"? And surely, if it be advisable in the interests of the private lunatic that his certification be controlled by the closer knowledge of his immediate medical attendant, then is it not equally desirable that the pauper patient should have the advantage of the opinion and skill of those who are in immediate and daily attendance upon him? Medical superintendents of infirmaries are, too, by virtue of their experience experts in lunacy diagnosis.

The Lunacy Act, therefore, in my opinion, requires altering in the interests of the lunatic—i.e., it ought to specially (and not indirectly) enjoin that the infirmary doctor (or "usual medical attendant" of the pauper) be certifier "whenever practicable." So much for law.

Finally, with reference to the ethical side of the question. What is the duty of a medical man when asked to visit a medical institution and examine the patient of a brother practitioner (for the justice cannot compel him to go)? Personally, I would absolutely refuse to be a party to such a practice at any fee however large. Of course I may be wrong, and I should like to have some expression of opinion from you on the matter.

This custom of calling in another surgeon exists, I believe, in a few workhouses and infirmaries, and in the public interest a discussion would be most useful. In my opinion the practice is a dangerous one and most unfair alike to the patient and his "usual medical attendant."

I am, Sirs, yours faithfully,

MARCUS MARWOOD BOWLAN, M.B., B.S. Dunelm., D.P.H. Cantab., Medico-Psychological Cert.,
Resident Medical Superintendent, St. George-in-the-East Infirmary; Visiting Medical Officer, St. George-in-the-East Workhouse.

Jan. 22nd, 1901.

P.S.—I have no monetary interest whatever in this matter.

THE INDICATIONS FOR LOCAL ANÆSTHESIA.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Jan. 19th, 1901, p. 197, is an annotation in which are detailed the circumstances attending the death of a child who died while undergoing an operation

at a provincial hospital. I have read the remarks, which are exceedingly succinct and concise, with great care, and personally I think your readers are under an obligation to the writer for the shrewd and experienced suggestions which are made. My thought on considering the subject-matter was that under the extreme and asthenic general condition of the little patient would not local anæsthesia for the performance of the abdominal operation have been more applicable than chloroform inhalation? I can, and so I know can many other surgeons, speak of the value and the perfect security of performing abdominal sections in patients after the previous employment in the area of the proposed operation of the hypodermic administration of eucaine. Without referring to a number of cases in which minor operations have been successfully and painlessly performed after the injection of the above-mentioned drug, I may further say that I have, without the slightest knowledge or exhibition of feeling on the part of the patient (as stated when questioned afterwards), performed the following abdominal operations: suprapubic cystotomy, an oöphorectomy, and within the last six weeks I have cut down upon the liver, explored it, and finally incised a large abscess, and clearing out the cavity concluded the operation, the patient (a young man) returning to his bed very little the worse for the procedure. I am, Sirs, yours faithfully,

Wolverhampton, Jan. 21st, 1901. T. VINCENT JACKSON.

THE EFFICIENCY OF LIQUID EXTRACT OF ERGOT.

To the Editors of THE LANCET.

SIRS,—In Professor Attfield's "Digest of Researches and Criticisms" on the British Pharmacopœia, prepared for the General Medical Council, he remarks that it is a matter of importance to collect opinions from practitioners as to whether or not the liquid extract of ergot is as trustworthy as the extract (ergotine); and if it is not to remodel the process for its preparation on that of the apparently satisfactory extract. Now ergotine is obtained by extracting ergot with alcohol, whilst the fluid extract is prepared by treating it with cold water. The universal experience of practitioners is, I think, that the latter is most uncertain in its effects and always liable to disappoint. It is also, as I can testify, of very variable strength and prone to decomposition. On the contrary, the solid extract popularly called ergotine is a most efficient drug and may be relied on to act almost with mathematical certainty.

I am, Sirs, yours faithfully,

Dublin, Jan. 19th, 1901. J. C. MCWALTER.

"ISOLATION HOSPITALS."

To the Editors of THE LANCET.

SIRS,—In reply to Mr. E. D. Agnew's letter on this subject in THE LANCET of Jan. 19th, p. 214, I beg to state emphatically that the second outbreak of scarlet fever did not occur till six days after the convalescents had returned home from the isolation hospital. The parents in each case are willing to testify to this, and to use the words of one of the mothers, "their skins were as clear as marble and their health perfect." The boy Neville returned from the hospital with an inflammatory discharge from the nose which was so severe that I have kept all the children of the house away from school—this is not yet quite well; and the desquamation suggested by Mr. Agnew in the case of the child Foster is some congenital cuticular shedding which she was suffering from when attacked and which I have often treated her for. There is not the slightest possible doubt that the second outbreak of scarlet fever was due to infection brought by the "return" cases from the Bishop's Stortford Isolation Hospital.

I am, Sirs, yours faithfully,

Stansted, Essex, Jan. 22nd, 1901. EDGAR PITTWAY.

OBTUSENESS OR ANIMUS?

To the Editors of THE LANCET.

SIRS,—In the review of my "Text-book of Pathology in Relation to Mental Diseases" in THE LANCET of Jan. 5th there is a statement so misleading and so damaging that I must request you to allow me to make an explanation regarding it. Fair criticism should always be welcome to an author, for he can invariably profit by it; unfair criticism, whether attributable to the obtuseness or to the animus of the reviewer, is for many reasons generally best left alone; but gross misrepresentation of facts, involving a serious reflection upon the author, can hardly be allowed to pass unchallenged.

The statement to which I refer is the following: "Many of the illustrations are taken from the standard works, such as those of Golgi, Lugaro, and others." Now, in the common acceptation of the term, a "standard work" is a book, and in this sense the writer of the review himself uses the word "work" in the two immediately succeeding sentences as well as in the first line of his critique. The information that your readers must therefore inevitably gather from the sentence I have quoted, taken in the context in which it stands, is that, in order to illustrate this text-book, I have been obliged to make free use of illustrations contained in already existing text-books. I have done nothing of the kind; the imputation is wholly false. The facts are that the "many illustrations" referred to by your reviewer comprise 14 figures out of 182 contained in my book, and that these 14 figures are taken, not from already existing text-books, but from recent papers in Italian neurological journals, and serve to illustrate that portion of the chapter upon the nerve-cells which purports to be nothing more than a critical digest of recent researches upon the normal and pathological histology of these tissue-elements. It is worthy of note that the "others" in the sentence quoted consist of two individuals.

I am, Sirs, yours faithfully,

W. FORD ROBERTSON.

Hill-square, Edinburgh, Jan. 14th, 1901.

*** We regret that the reviewer should have failed to make clear how many illustrations in Dr. W. Ford Robertson's book were not original and what was their exact source. We wonder that Dr. Robertson did not hesitate before charging the writer of a favourable review with obtuseness or animus.—ED. L.

ROBERT LOUIS STEVENSON: "FEVER" AND MOSQUITOES.

To the Editors of THE LANCET.

SIRS,—It is interesting to note that in 1888 Robert Louis Stevenson wrote of Atuona in "The Marquesas" as follows: "In Atuona, a village planted in a shore-side marsh, the houses standing everywhere intermingled with the pools of a taro-garden, we find every condition of tropical danger and discomfort; and yet there are not even mosquitoes—not even the hateful day-fly of Nuka-hiva—and fever and its concomitant, the island fe'efe'e, are unknown." Stevenson merely records the facts; but in these days this note, made by an accurate observer, of a spot where the absence of mosquitoes coincided with the absence of fever and of elephantiasis is worthy of remark.

I am, Sirs, yours faithfully,

Leeds, Jan. 18th, 1901. H. D. O'NEILL.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Beer Inquiry.

THE inquiry before the Manchester city coroner regarding the death of one of the sufferers from arsenical poisoning is concluded. The jury returned an open verdict, to which a rider was added that a vote of censure should be passed on Messrs. Groves and Whitnall, Limited, the brewers, Messrs. J. Nicholson and Sons, Limited, the sulphuric acid manufacturers, Dr. Morris, the consulting chemist, and Mr. Cook, works chemist to Messrs. Bostock, for carelessness. This, as the coroner said, is practically a verdict that death was due to poisoning by arsenic. He said, moreover, that he did not embody the censure in the verdict because it was a rider. He agreed with a remark of Mr. Fletcher Moulton that there was no evidence of carelessness on the part of the brewers. In his address to the jury the coroner said that the thanks of the whole community were due to Dr. E. S. Reynolds for the part he had taken in the case. He also

thanked Mr. C. H. Tattersall for the prompt and decisive action which he took.

Prestwich Union.

At the meeting of the Prestwich Board of Guardians on Jan. 17th, the overcrowded state of the workhouse was again the subject of discussion. During the previous fortnight there was a remarkable increase in the number of tramps admitted—from 69 to 200. No explanation of this seems to have been given, but doubtless the chronic or professional tramps have their seasons of migration like the swallows. There has been no exceptional severity of the weather to account for it; on the other hand, the weather has been unusually mild. There was also an increase of 50 people in the workhouse as compared with the previous year, and in the hospital some of the patients "had to sleep in a passage in the absence of room for them in the wards." As regards out-door relief, 3030 persons had been relieved during the fortnight as compared with 2589 in the corresponding period of last year. Yet this is said to be a time of great prosperity. The question of extending the buildings is to be considered. Mr. Jenner Fust had written to ask if anything had been done with regard to taking the children out of the workhouse. In answer to this inquiry it was said that "by arrangement with the Manchester guardians the indoor children ..... were sent to the Swinton schools and that there were no children in the workhouse over the age of four years." All who know the excellent management of the Swinton schools will be ready to acknowledge that they are a great improvement on any workhouse. At the same time, they must be looked upon as barrack schools, though of the highest class, so that there cannot be much approach to family life, and the small children must feel, though perhaps they would be unable to express, the lack of the personal interest and individual affection which even a foster-mother may give where she has only a few in her care. Then, too, the imbeciles and epileptics are a difficulty. The chairman said that till the former can be removed from the workhouse, or the workhouse can be enlarged, the classification of the inmates wished for by the Local Government Board cannot be carried out. One member hoped that in any scheme of extension proper provision would be made for these two classes who are "at present herded together, which ought not to be." This discussion showed that there was a wish to improve matters, but it ended with deferring "the consideration of further extension of the workhouse buildings till the new board has been elected in March."

Chorlton Union.

The guardians of the Chorlton Union met on Jan. 18th, and their proceedings, like those of their colleagues at Prestwich, show how humane is the feeling now actuating those who have the care of the very poor. A letter had been received from Mr. Jenner-Fust containing inquiries similar to those sent to the Prestwich Board of Guardians. It was stated in reply that as regards the children as many as possible were removed to the cottage homes at Styal, and that when certain extensions were completed the children still remaining in the workhouse would be taken there. The old men and women had been placed in a separate part of the workhouse and the men were allowed to go out every afternoon. The pauper suit had been abolished—which must be a comfort to sensitive souls, if any such are left. The guardians were "also anxious to provide room for aged married couples to live together." The question of the new dietary order of the Local Government Board was also considered. The reply was to the effect that the medical officer of the workhouse was quite satisfied with the dietary table now in force; that the new dietary would probably cost an additional £1000 a year; that it was not needed in the union and that it was not asked for by the Poor-law guardians of the country; and that they "were in favour of the new order being made optional till it had been proved practicable from its working by some unions in both urban and rural districts." *Fiat experimentum*, &c.

Manchester Union.

The Manchester Board of Guardians recently had to consider a letter similar in purport to those received by the Prestwich and Chorlton boards. The recommendations were: (1) That children should be removed from the workhouse; (2) that where out-door relief was granted to aged deserving persons it should be adequate in amount; and (3) that aged deserving inmates should be classed separately and should be granted special privileges. As to the first point the chairman said the great majority of the children were at the Swinton schools, and when some new arrangements were completed, all but the infants and the sick would be sent there. They were also meeting the wishes of the board as to the second point; and as to the third, should new arrangements for the removal of imbeciles and epileptics from the workhouse be made, either by the erection of a joint asylum or otherwise, the space so gained would enable the guardians "to proceed further in the direction of classification of the aged deserving inmates."

"Manchester Wheelers'" Generosity.

The body of cyclists known as the Manchester Wheelers at their annual meeting held about a fortnight since voted a sum of £50 to the Children's Hospital, Pendlebury.

Salford City Hospital.

At the meeting of the board of the Salford Hospital on Jan. 17th, the chairman reported the receipt of a donation from Mrs. Charlotte M. Pilkington, of Llandudno, of £1250, for the endowment of a bed to be called the "Hope" bed. A vote of thanks was passed.

Jan. 23rd.

WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Unqualified Practice censured by a Coroner.

THE disastrous results which so often follow the treatment of an injury by a "bone-setter" were conspicuously manifested at an inquest held at Merthyr on Jan. 18th. On the Saturday evening prior to last Christmas Day a young collier was carrying home a four and a half gallon cask of beer for consumption on Sunday. Incidentally I may remark that one result of the closing of public-houses in Wales on Sunday is the joint purchase on Saturday by two or three colliers of a small cask of beer which is usually emptied before Monday. The Merthyr collier dropped the cask on to his left foot and caused a compound fracture of the left toe. Instead of consulting Mr. T. J. Webster, the colliery surgeon, he went to a bone-setter named Price who, it appears, has a sufficiently large connexion to enable him to engage as his assistant his son-in-law who up to a few years ago worked as a collier. Price treated the wound with ointment, oil, &c., until the joint became gangrenous, when the patient was persuaded to go into the hospital where he died from septicæmia. The coroner, when summing up the evidence given at the inquest, spoke of the treatment of the bone-setter as "botching" and said: "I consider these kind of men are absolutely irresponsible people and they do a great deal of mischief. I am continually hearing of cases in which they make a terrible mess of patients, and I firmly believe that if a properly qualified doctor had attended this case at the commencement there would have been a very good chance of saving this man's life." It is particularly pleasing to be able to record these remarks of Mr. R. J. Rhys a legal coroner.

Medical Appointments at Swansea.

The Swansea board of guardians have decided to appoint a resident medical officer to the workhouse, and according to the report in the local newspapers it is proposed to engage a "young medical practitioner" at a salary of £100 per annum. The board has been well advised in adopting a qualifying prefix, for the salary offered is not very likely to attract a practitioner of much experience, and it is not improbable that the Swansea board may have as much difficulty in obtaining the services of a medical officer as the Bristol corporation who obtained no response to their advertisement for a medical superintendent of the Ham-green Fever Hospital, and have been obliged to raise the salary offered from £100 to £150 per annum. The guardians also propose to appoint a medical officer for No. 1 district of the Swansea Union who shall devote the whole of his time to the duties of his office and shall be paid at the rate of £120 per annum, together with the vaccination fees which are estimated at £200. This stipend can hardly be said to err upon the side of liberality.

Crematorium near Cardiff.

The crematorium which has been recently erected at Hull is not the first municipal crematorium to be established in England and Wales. Only last year the Cardiff corporation

through their medical officer of health drew public attention to the fact that cremation could be carried out in the crematorium on Flat Holm Island, which has been in an efficient state since 1895.

Police Surgeons in Cardiff.

There has hitherto been only one police surgeon for the whole of Cardiff and for some years the post has been held by Dr. T. Wallace. In consequence of the great increase in the size of the town the watch committee has now decided to appoint three surgeons, each with a defined area. One of these is to be chief surgeon and in addition to his divisional duties he will be required to examine police recruits and to examine lunatics if requested to do so by the magistrates. The druggists in the borough were desirous of dissociating the dispensing of drugs from the duties of the police surgeons and urged the appointment of three police druggists, but the watch committee would not entertain the suggestion.

Death-rate of Caerleon.

The unusually low death-rate of eight per 1000 is reported from Caerleon in Monmouthshire for the year 1900.

Remuneration of Colliery Surgeons.

The medical practitioner of to-day amongst the mining class is not so happily circumstanced as formerly, when the doctor, the parson, and the manager were regarded as the three important personages in each colliery township or village, and all lived in contentment and happiness. To-day, however, when the colliers have forced into them all the ethics and vocabulary of paid agitators and are tutored in all the seductive influences of socialism they become discontented among themselves and adopt an attitude of tyranny towards any persons whom they may have in their power. In several parts of South Wales and Monmouthshire, especially where the poundage system is in vogue, disputes are pending on the ground that the medical man earns too much money. At present the rate of wages are exceptionally high, and upon this basis the amateur statistician computes the salary of the colliery surgeon. He gives little or no thought to the recent five months' strike when the medical fees were *nil*, though drugs and assistants had to be provided. Now that an opportunity arises for recouping the loss then entailed the men agitate for a reform in the mode of payment. Noticeably is this the case at Tredegar, where Mr. G. A. Brown practises, and at Cwmsiflog, where Mr. R. T. E. Davies holds the appointment of colliery surgeon. In each of these districts the colliers wish to appoint a surgeon at a fixed salary and to themselves defray all the expenses of drugs, assistants, &c. The colliery surgeons, on the other hand, prefer to be paid by a poundage—usually 3*d.* in the £1—upon the men's earnings and to discharge all the expenses of the practice.

North Devon Infirmary, Barnstaple.

At the quarterly meeting of the governors of the North Devon Infirmary held on Jan. 15th it was decided that the salary of the house surgeon should be £80 instead of £120 as formerly. There was a considerable discussion in which it was urged that the reduction would be mistaken economy and there was an amendment that the salary be £100. The former house surgeon had received £50 for acting as secretary to the infirmary, but it was determined in future that an honorary secretary be appointed, £20 being allowed for the assistance of a clerk.

West Cornwall Dispensary and Infirmary, Penzance.

The annual meeting of the friends of the West Cornwall Infirmary and Dispensary was held on Jan. 16th, under the presidency of Prebendary Hedgeland. The report stated that 1629 out-patients had been treated during 1900, as against 2171 in 1899; 115 in-patients had been admitted, as against 165 in the previous year; and 68 patients had been sent to the convalescent home. The financial statement showed that the income amounted to £882 and the expenditure to £879. The income of the convalescent home had been £403 and there was a favourable balance of £88.

Bath Eastern Dispensary.

The annual meeting of the friends of the Bath Eastern Dispensary was held on Jan. 17th, under the presidency of the Mayor of Bath. The medical report stated that 4364 patients had been treated during the year, including 899 patients who had been attended at their homes. The financial statement showed that the income amounted to £636 and that a favourable balance of £61 remained. The committee added that there had been considerable difficulty in obtaining the services of a resident medical officer owing to the war in South Africa, but recently Dr. W. H. Lowman had been appointed, and Mr. O. A. G. Collins had kindly performed the duties during the vacancy.

Health of Cornwall.

The report of the sanitary committee of the Cornwall County Council for 1900 shows that during the year the birth-rate was 24·4 per 1000, as against 24·4 in 1899. The general death-rate was 16·4 compared with 15·8 in the preceding year. The zymotic death-rate was 1·01 per 1000, which is practically the same as in 1899. The slight increase in the death-rate is attributed by the committee to the severe epidemic of influenza in the early part of 1900.

Jan. 22nd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Urban Mortality in Scotland in 1900.

THE estimated aggregate population of the eight principal towns of Scotland at the middle of 1900 was 1,606,935. The series of the Registrar-General's monthly reports applicable to these towns being now completed for the year, an examination of them shows that during that period the total number of deaths was 33,368, or at the rate of 20·76 per 1000 inhabitants. Of the deaths 16,393 occurred in Glasgow, 5878 in Edinburgh, 3391 in Dundee, 2864 in Aberdeen, 1230 in Leith, 1608 in Paisley, 1298 in Greenock, and 706 in Perth. The respective annual rate of mortality on the estimated population of the individual towns was as follows per 1000 inhabitants: Glasgow, 22 03; Edinburgh, 19·44; Dundee, 20·24; Aberdeen, 19·05; Leith, 15 67; Paisley, 20·55; Greenock, 21·10; and Perth, 22·91. Of the 33,368 deaths, 4543 were due to specific febrile or zymotic diseases, three to parasitic diseases, 155 to dietetic diseases, 6355 to constitutional diseases, 2454 to developmental diseases, 17,027 to local diseases, 1396 to violence, and 1435 to ill-defined or not specified causes. Of the aggregate general mortality 12,079 were deaths of children under five years of age. With regard to the more familiar zymotic diseases, measles was marked in April, June, and July in Glasgow; in November and December in Aberdeen; in January, February, March, and July in Paisley; and in January in Perth. Whooping-cough prevailed in Glasgow in April, May, June, July, August, November, and December; in Aberdeen in May; in Paisley in March and July; in Greenock in August, September, October, November, and December; and in Perth in January, February, and March. Influenza was marked in Edinburgh in February. in Aberdeen in January and February, in Paisley in January, and in Perth in February and March, while enteric fever was prevalent in Paisley in September.

Edinburgh University Court.

At a meeting of the Edinburgh University Court on Jan. 14th the following were appointed additional examiners for the medical degrees:—Mr. J. Bretland Farmer (botany), Dr. John Gibson (chemistry), Dr. Robert Howden (anatomy, including anthropology), Dr. D. Noel Paton (physiology), Dr. William Russell (pathology), Dr. John C. M'Vail (medical jurisprudence and public health and sanitation, sanitary law, and vital statistics), Dr. Allan Macfadyen (public health laboratory work), Dr. John Shaw McLaren (surgery), Dr. James O. Affleck (practice of medicine), Dr. Alexander James (clinical medicine), and Dr. John W. Ballantyne (midwifery).

Cremation in Scotland.

The annual meeting of the Scottish Burial Reform and Cremation Society was held in Edinburgh on Jan. 16th, Professor Sir Henry Littlejohn being in the chair. Sir Henry Littlejohn, in moving the adoption of the report, which has been already alluded to in these columns, said that in 1865 Professor Sir James Simpson directed his attention to the evils connected with the intermural interments and was exceedingly anxious to have a crematorium established. Sir James Simpson fixed on Hunter's Bog as a suitable site, but public opinion was strongly opposed to such a violation, so to speak, of the sanctity of that spot. Sir James Simpson had also expressed to him

his determination to be cremated. Sir Henry Littlejohn then went on to relate how, through the request of Dr. Robert Lee, he had been induced to investigate the condition of Greyfriars Churchyard and how, as the result of his investigations, the town council at once agreed to the closure of that burying-ground. One churchyard after another was taken up and closed, ending with that of St. Cuthbert's. As one of the directors of the society he had carefully examined the crematorium at Glasgow and had been much pleased with what he had seen and with the manner in which the operation of cremation was carried out there.—The report submitted by the honorary secretaries stated that the number of cremations in Scotland showed a steady yearly increase, the total number since the opening of the crematorium at Glasgow being 75. Dr. Ebenezer Duncan, speaking in favour of the adoption of the report, said that the late Duke of Argyll left definite instructions that his body was to be cremated, but these instructions were disregarded by his relatives; also that the late Marquis of Bute would have warmly advocated cremation if the Church of Rome had withdrawn its opposition.

Appointment of Medical Officer of Health of Leith.

The post of medical officer of health of the burgh of Leith, which had been rendered vacant by the resignation of Dr. W. Leslie Mackenzie on his appointment as medical superintendent under the Local Government Board, was filled up on Jan. 17th at a special meeting of the Leith Town Council by the appointment of Dr. William Robertson of Paisley. The new medical officer of health will begin his duties not later than Feb. 15th at a salary of £400 per annum.

The Scottish National Red Cross Hospital.

The medical and surgical officers of this hospital who have recently returned from South Africa were entertained at a complimentary dinner in Glasgow on Jan. 18th. The Marquess of Breadalbane, K.G., occupied the chair and there was a large attendance of medical men, including Professor Chiene, Dr. G. T. Beatson, Professor H. E. Clark, Dr. John M. Cowan, Dr. John Aitken, Dr. Alexander Garrow, Dr. Robert Stirling, Dr. George M'Intyre, &c. In reply to the toast of "Our Guests, the Officers of the Hospital Staff," Colonel Cayley, R.A.M.C., Commandant, and Professor H. E. Clark gave an account of the work performed by the hospital and referred generally to the demands made on the medical profession by the conditions of war. Sir David Richmond, a member of the South African Hospital Commission and a former Lord Provost of Glasgow, bore testimony to the excellent work performed by the Scottish Hospital which he had visited at Kroonstad. In the afternoon of the same day a reception was held by the Ladies' Executive Committee to meet the nurses of the hospital. This also was largely attended. The main credit of the organisation of the Red Cross Hospital is due to Dr. G. T. Beatson and Dr. Donald Mackintosh who by their enterprise and public spirit secured an appropriate method in which the patriotism of the Scottish people could express itself. At one time some petty local jealousies threatened to interfere with the success of the movement, and though these were not altogether allayed they exercised no practical effect on what was really a national enterprise. The best testimony to the satisfactory equipment of the hospital was the fact that the Government offered to purchase it as it stood. In reply to this offer the committee resolved to present it as a free gift on condition that it was continued under the name of the Scottish National Red Cross Hospital, and it is on these terms that, with some members of the original staff, the hospital now remains in South Africa.

Interesting Legal Case.

A medical man in Glasgow has recently acquired a house in one of the residential terraces in the west-end of the city which he proposes to use as a private hospital or nursing home and has found himself in consequence involved in legal proceedings, for the proprietors of the neighbouring dwelling-houses object to his scheme and have sought to frustrate it by an action in the Court of Session. In this, however, they have not been successful. Their case was based upon an agreement which provided that the buildings erected on the ground concerned "shall permanently continue as dwelling-houses and shall not be converted into shops, warehouses, or trading places of any description," and they contended that the proposed use of the house amounts to the conversion of it into a trading place for the purpose of money-making. They also urged that "the unpleasant sights and sounds, as well as the unpleasant odours of antiseptics and drugs, the great traffic entailed by the arrival and departure of patients, nurses, consulting doctors, friends of patients, and [most unkindly] undertakers" constitutes a nuisance in such a neighbourhood. In reply the defender denied that any nuisance would be created and stated that the house "was not intended to be a direct source of profit." He therefore claimed that there was no breach of the agreement preventing the establishment of a trading establishment, and for this contention he has now received the sanction of the law.

University of Glasgow.

The official statistical report for the year 1899–1900 has just been issued. It contains, as usual, a full list of the University officials and their salaries, and numerous tables showing the number of the students in the various classes and the graduates in the different faculties. In medicine there were 221 degrees conferred. Three of the M.D. graduates were awarded "Honours" and six received "Commendation." Only one M.B. gained the highest distinction, but six were "commended." Amongst the benefactions received during the year are a sum of £11,000 from the trustees of the late James B. Thomson, to be applied in the reconstruction of the anatomical department; a sum of £1000 given by Lord Kelvin, to be used for the encouragement of experimental investigation; £2500 from the late Rev. Alex. Robertson to found a lectureship in defence of the Christian religion; and numerous smaller amounts for the establishment of bursaries, prizes, &c.

Hospital Sunday in Aberdeen

The results this year have been rather disappointing, as there were collections in more churches than was the case last year. The total amount subscribed up to date is about £1200.

Outbreak of Small-pox in North Scotland.

Several cases of small-pox have been discovered in Burghead (on the Moray Firth) and Elgin, and the infection has been traced as coming from Glasgow. Three cases have also occurred in Aberdeen since the beginning of the year.

Epidemic of Small-pox in Glasgow.

Glasgow is suffering from a somewhat severe epidemic of small-pox. Upwards of 50 fresh cases have occurred since yesterday, making a total of 253.

Jan. 22nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish Local Government Board and the Isolation of Tuberculous Patients.

THE Irish Local Government Board have notified the Downpatrick Board of Guardians that, having regard to the infectious nature of pulmonary tuberculosis, it was, in their opinion, highly desirable that provision should be made in workhouse infirmaries for the treatment of persons suffering from this disease in separate wards—that was to say, wards to which patients otherwise affected were not admitted. The guardians have been requested to be so good as to give this matter their early and careful consideration. The inspectors of the Board have from time to time called attention to the matter and the guardians are now strongly advised to have steps taken to isolate consumptive patients. The medical officer of the workhouse was on Jan. 12th directed to prepare a report on this most important question for the guardians.

Medical Fees.

One of the frequently discussed questions in medical circles came up for a legal decision before the Recorder of Belfast on Jan. 10th. Dr W. Calwell, of Duncairn-gardens, Belfast, sued a man in his neighbourhood to recover one guinea "for professional services rendered." Dr. Calwell had been engaged to attend the wife of the defendant at the time of her confinement, but when this occurred he was not called in, a practice apparently common enough among the working classes. Evidence having been given Dr. Calwell was nonsuited on a technical point, as he based his action "for services rendered" instead of upon a "breach of contract." It is a pity that such an unsatisfactory conclusion was arrived at, as medical men are sometimes put to

great inconvenience and distinct loss by treatment such as Dr. Calwell received in this case.

Bangor Dispensary, County Down.

Mr. J. F. Mitchell, of Newtownards, has been elected dispensary medical officer for the Bangor district of the Newtownards Union at a salary of £110 per annum, and £14 per annum as medical officer of health to the Bangor Rural District, and £10 per annum as medical officer of health of the Urban District of Bangor, together with vaccination and registration fees.

The Belfast Lunatic Asylum.

At the monthly meeting of the committee of this asylum held on Jan. 14th the resident medical superintendent, Dr. William Graham, submitted a valuable report upon the villa or colony type of construction, in which he pointed out that the special features in this type of asylum construction are the segregation of the inmates into communities, where they live in more domesticated and home-like style than would be possible in a large building. The accommodation for patients consists of two sections, one a hospital with special arrangements and the other a congeries of villas with simpler arrangements. The advantages claimed for this system are: (1) more homeliness and less institutional character; (2) more careful classification of patients; (3) lessened cost of construction; and (4) facility for enlargement. Two great advantages of the villa type are: (1) a small part may be erected and occupied bit by bit before the completion of the whole; and (2) in case of enlargement a villa or villas can be added as required without any disturbance of existing arrangements. An animated discussion followed, and it was finally decided to print and circulate the report among the members of the committee and to consider the matter at the next meeting of the committee, the medical superintendent in the meantime to collect all possible information in regard to the matter. At the same meeting the report of the inspector of lunacy, Mr. G. P. O'Farrell, was brought forward, in which it was pointed out that the overcrowding on the female side of the asylum was very serious, and that the necessity for relieving it had become pressing and urgent. While the estate at Purdysburn had been acquired five years ago no steps had yet been taken towards the actual building of any part of the new asylum. Although all credit was due to the medical superintendent for his efforts to modernise the old building, yet nothing, the inspector said, could materially alter the back part of the asylum, which was dingy and cheerless in the extreme, and it was here that the larger part of the accommodation was situated. When the forward condition in Scotland in reference to the treatment of the insane was contrasted it was remarkable how little a desire for progress pervaded the general population of the North of Ireland. Unless some definite action was taken in reference to the female patients he (Mr. O'Farrell) could not report to the Lord-Lieutenant that the committee had fulfilled the duty of providing and maintaining sufficient accommodation for the lunatic poor of the city which was imposed on them by the Local Government (Ireland) Act, 1898, and the fulfilment of which duty was made a condition to the payment of the Government grant in aid of maintenance. The inspector regretted that pulmonary phthisis (the most fatal of all diseases amongst the insane in Irish asylums) showed a tendency to increase, as might be expected in an old and overcrowded institution. This report of the inspector, so serious in the faults which it points out in the present condition of the asylum, it has been arranged shall be considered at the next meeting of the committee. It is to be hoped that, taken in connexion with the report of the medical superintendent on the villa type of asylum, we shall in the end have in Belfast an asylum constructed on modern lines worthy of the city and of the North of Ireland.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Magnetisers officially declared to be Illegal Practitioners.

THE medical profession has, from a professional point of view, recently won a signal victory in the law courts—a victory, too, which is all the more gratifying because such victories are so rare. The Court of Cassation has given a final judgment in a matter which has been undecided for years, and has pronounced that persons who treat illnesses by magnetism without possessing the degree of doctor of medicine are guilty of the offence of illegal practice. Hitherto the law on the point has been very indecisive from the legislative point of view. The law of 1892, which laid down regulations for the practice of medicine in France, says absolutely nothing about magnetisers—a fact all the more singular when it is remembered that these gentry had several times been mentioned in the course of the Parliamentary debates which preceded the passing of the law. On this account the courts of law, in the event of a magnetiser being prosecuted for illegal practice, gave the most contradictory judgments. In 1893 the Tribunal of the Seine convicted a magnetiser and found him guilty of illegal practice. In 1894 a woman was convicted of the same offence by the Tribunal of Mans, but she appealed to the Angers Court of Appeal, which acquitted her, giving as its opinion that she was not guilty of illegal practice because she used neither drugs nor surgical manœuvres. This judgment had the result of filling the whole district with magnetisers who pursued their industry unchecked. In 1896 a magnetiser, by name Mouroux, who was prosecuted by the Medical Association of Angers, was acquitted by the Correctional Tribunal of that town; the association appealed to the Angers Court of Appeal, which, however, only confirmed the judgment. The Union of the French Medical Associations came to the aid of the Angers association and the case was carried to the Court of Cassation so that a final judgment might be obtained in a matter affecting the whole medical profession. The Court of Cassation, however, had its hands quite full with the Dreyfus *affaire* and took four years to decide the question. During the interval, however, in 1898, a magnetiser was convicted by the Tribunal of the Seine. At last, on Dec. 26th, 1900, the Court of Cassation delivered judgment in the Mouroux case. The counsel in charge of the case (*conseiller rapporteur*) had decided in favour of the magnetiser, but the court, evidently influenced by the remarkable report laid before the recent Congress of Deontology by M. Dupré and M. Rochet, had no hesitation in giving judgment against magnetism. As a matter of fact the situation was very delicate. The magnetiser argued that as all medical men declared that the practices of his fraternity were pure charlatanism and of no value whatever, he and his colleagues employed no real medicaments and that therefore they could not be guilty of illegal practice. True, they might be accused of swindling, but it would be necessary to prove that they had demanded money from patients—a thing almost impossible to confirm and one which would need a careful consideration of every particular case. The counsel for the medical associations got out of the difficulty very cleverly. He argued that magnetism was a therapeutic agent of the very first order, one which should not be used except by skilled hands and the use of which should be forbidden to those who had not a medical diploma. It certainly cost the dignity of the medical profession something to allow such honour to the fantastic gesticulations of magnetism, but it was the only way in which to arrive at the desired result—namely, the forbidding of magnetisers to "practise."

Muscle Serum.

At the meeting of the Academy of Sciences held on Dec. 31st M. Riche proposed to call by the name of "muscle serum," or "myoserum," the juice obtained by pressure from meat, which is, according to him, the sole portion of the raw meat gifted with curative properties as regards experimental tuberculosis in the dog. Using raw beef in a strong press 33 per cent. of juice can be obtained. It is a red fluid, amphoteric or feebly alkaline in reaction, and coagulable by heat or nitric acid. Besides mineral matters one kilogramme contains about 50 grammes of albuminoids, of which 10 per cent. is hæmoglobin. Despite its richness in albuminoids the serum passes through filter paper like water and so can be easily freed from its fat and formative elements. It is very unstable and even if kept at a temperature of 0° C. putrefies in a few days. In summer at ordinary temperatures it undergoes change within an hour or two. It must therefore be used as soon after preparation as possible. Administered by the mouth to dogs in doses of 20 cubic centimetres per kilogramme of body-weight it brought about a cure in cases of experimental tuberculosis. Given subcutaneously or intravenously it is very toxic and a dose of five or even three cubic centimetres per kilogramme of body-weight brought about a very notable

lowering of blood-pressure. The animals vomited and had bloody diarrhœa, dying in from 24 to 48 hours, or sometimes less, in a state of coma. Post-mortem examination showed intense congestion of the intestines and of the liver; the coagulability of the blood was not altered, neither were the kidneys affected. When coagulated by heat the serum was found to be not toxic.

Separate Wards for Noisy or Delirious Hospital Patients.

A recent meeting of the Hospital Medical Society was the scene of an informal discussion as to the best remedy to be found to prevent those deplorable cases in which delirious patients try to commit suicide, attack their fellow sufferers, or attack the nurses. M. Le Gendre suggested that in every hospital there should be a special ward for such patients, so that they could be carefully watched. As a matter of fact no such facility exists. If a patient goes out of his mind and his state of health permits he is sent to a lunatic asylum and the ease with which such transference is made on a simple order of the head of the hospital has given rise to some objections which are quite justified. The custom is unjust to ordinary lunatics who require various certificates before they can be placed in the asylum. Only too often the head of a hospital simply gets rid of a troublesome patient by sending him to an asylum, and very often such patients are unfairly tainted with the stigma which attaches to anyone who has become a definitely certified lunatic. On the other hand, there is no doubt that noisy or delirious patients, whether suffering from the delirium of fever, from post-operative mania, or from puerperal mania, are a constant source of danger to themselves, to other patients, and to the nurses. The society was in perfect accord with the proposal of M. Le Gendre and various speakers related instances of the imperfect arrangements existing at the hospitals with which they had to do. M. Chauffard said that things were so bad at the Cochin Hospital that visitors were not allowed. M. Barth said that at the Necker Hospital there was but one male night superintendent and one female, and added that the organisation of the hospital was as bad as before the Revolution except that they no longer put two or three patients into one bed. A complete plan of reform should be drawn up and submitted to the Assistance Publique. M. Le Gendre, however, preferred to demand reforms one by one as a plan more likely to meet with success, and the society accordingly resolved that every hospital should provide a ward for the isolation of those temporarily mentally afflicted and that copies of this resolution should be at once forwarded to the Director of the Assistance Publique, to the Municipal Council, and to the Minister of the Interior. A committee was also elected to deal with the question of hospital reform, composed of M. Millard, M. Faisans, M. Troisier, M. Le Gendre, M. Chauffard, M. Barth, and M. Beckler.

Jan. 21st.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Tetanus following Injections of Anti-diphtheritic Serum.

THE greatest consternation has been caused during the past week throughout Northern Italy by the occurrence of a number of deaths from tetanus following upon the injection of anti-diphtheritic serum. It appears that diphtheria has of late been very prevalent in Lombardy and Venetia, and a large demand had in consequence arisen for the curative serum prepared by the Istituto Sieroterapico of Milan. The first alarm came from Valdobbiadene in the Province of Treviso, where four children who had been treated for diphtheria with the serum fell victims to tetanus. Reports of similar tragedies followed from Chiudino in Bergamo, from Prato Sesia and Boca in Novara, from Brescia, and from Milan itself, making a total of some 20 cases, all of which had been injected with serum from the above-mentioned institute. The Government promptly ordered the serum to be seized wherever it could be found and set on foot a searching inquiry in order to discover how it came to be contaminated. At present there are only surmises on this point, but it has been already ascertained from the register of the institute that the serum used in most of the fatal cases belonged to one particular lot, decanted on Nov. 22nd from a flask containing three litres into a series of 306 vials, each of which was closed, sealed, and numbered, and the whole of which were consigned to the firm of Erba of Milan, by whom again they were distributed to purchasers in the same condition as that in which they had been received from the institute. One case of tetanus, that at Milan, appears, however, to have been injected with serum prepared towards the end of December. Many more injections are known to have been made in the last few days with serum belonging to the same suspected stock with results which will doubtless prove equally disastrous. The Istituto Sieroterapico of Milan, which would thus seem to be responsible for a terrible mistake, is under the general direction of Professor Belfanti, assisted by Dr. Airoldi and Dr. Zenoni, to the latter of whom is entrusted the preparation of the anti-diphtheritic serum. When visited by the Inspector-General of Sanitation, Santoliquido, everything in the institute appeared to be in perfect order and a minute investigation will evidently be necessary to disclose the origin and author of the fatal blunder. Fortunately a sample was preserved of each lot of serum as it was prepared, so that it will be possible to subject to microscopic, chemical, and bacteriological analysis all that has been issued from the institute and so to discover any that may have been contaminated, and this is now being done. So far no tetanus bacilli have been detected in the suspected serum and it is thought that the symptoms to which its injection into the diphtheria patients gave rise may have been caused by tetanus toxin alone. As is only natural, under the fear inspired by these fatalities many parents have already refused to allow their children to be treated with antitoxin injections—a very deplorable fact in view of the prevalence of diphtheria and the undoubted value of good serum in its treatment. The Superior Council of Sanitation have under consideration a law for regulating the manufacture and sale of serum, vaccine virus, &c., with the object of preventing the occurrence of such fatal mistakes in the future.

The Proposed Amendment to the Law regulating Foreign Practice in Italy.

The exact scope of the alteration proposed in the present law relating to foreign practitioners will be seen from the subjoined translation of the new clause of the Bill which has now been presented by Santini for the approval of the Chamber of Deputies. The article in the sanitary law under which foreign practice is now sanctioned, after forbidding the exercise of the profession of medicine, &c., to those who have not been duly qualified by some authorised licensing body in Italy, concludes as follows:—

> From this prohibition are excepted foreign physicians and surgeons expressly called for special cases, and those who, possessing the diploma of a foreign university or school of medicine, exercise their profession among foreigners only.

The proposed law substitutes for this clause the following:—

> From this prohibition are excepted foreign physicians and surgeons expressly called for special cases or attached exclusively to the service of a particular person or family whom they accompany in travelling, and those who, possessing a diploma of a foreign university or school of medicine, exercise their profession among their compatriots only, always provided, however, that they [i.e., the foreign physicians and surgeons] belong to a State which accords to Italian physicians and surgeons reciprocity of treatment in regard to academic degrees and freedom of practice.
>
> On the same conditions as the above those foreign physicians and surgeons are also excepted who possess diplomas of universities or schools of medicine considered by the Superior Council of Public Instruction as equivalent to those conferred by the universities or schools of medicine in Italy.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

Plague in Constantinople.

ON Jan. 7th a man died here with symptoms of bubonic plague. The deceased, who was a boatman in the service of the police, fell ill at Beicos, a village on the Asiatic shore of the Upper Bosphorus, and for about eight days lay at a coffee-house, where he was examined by several medical men who considered the disease to be pneumonia due to influenza which is at present epidemically prevalent in Constantinople. Ultimately he was conveyed by his friends to Scutari, a suburb of Constantinople, and a bubo was there found in his left groin. The authorities then removed him to

the hospital of the Civil Medical School at Katirza, where he died in a few hours. When medical men from the Bacteriological Institute arrived for the purpose of making a microscopical examination of the contents of the bubo it was found that rats had entered the room where the body lay and had eaten the left side of the mouth, a portion of the left cheek, and the external genitals. The pulp of the bubo contained an enormous number of plague bacilli. All the places at which the deceased had stayed and the steamboat on which he had travelled from Beicos to Scutari have been disinfected, the small boats used for his conveyance from Scutari to Katirza have been burned, all persons who have been in contact with him are under strict observation and their wearing apparel has been burned, the officials of the hospital have received injections of anti-plague serum, and the hospital as well as the medical school has been surrounded by a sanitary cordon. But the rats! It has several times been proposed at the International Sanitary Commission that a stock of the Danitz culture for the destruction of rats should be brought from Paris, but this has not yet been done. In Russia, Roumania, Bulgaria, and Greece arrivals from Constantinople are now subjected to disinfection and 10 days' quarantine. The International Sanitary Committee was convoked three times last week in order to consider the measures to be taken for preventing the spread of the disease. At these meetings a feeling was expressed that the city ought to be thoroughly cleansed, that the inspection of dead bodies should be better attended to, that careful observation should be kept upon places of public resort, such as refreshment houses, cafés-chantants, and bazaars, and that the public closets should be cleansed and supplied with disinfectants. The British sanitary commissioner, however, declared that it would be very dangerous to have a thorough cleansing of the city, and the sanitary commissioner of the United States of America proposed that the Turkish Government should be informed that it was almost hopeless to expect good results from attempts to cleanse cities where the streets are narrow, badly paved, and bordered by high buildings, and where the houses are built back to back and so disposed as to exclude sunlight and fresh air. The American commissioner thought that the Government ought to prohibit the building of back-to-back houses and he quoted the case of Bombay where great sums of money had been spent almost to no purpose in cleansing and disinfecting; but the council did not take action in accordance with his proposals because it would obviously be a long time before the good effects of such measures could make themselves felt.

Public Health of Constantinople.

Constantinople is a city which in many respects falls short of the requirements of modern hygiene. The houses are badly built, and there are very few of them which the sun enters; the streets are exceedingly narrow and not paved, except some of the principal ones; and the water-supply is very bad, although the charge made to the consumer is high. It is indeed astonishing that the death-rate is not greater than it is. The number of the inhabitants is not exactly known, but it is estimated at about 800,000. The number of deaths of civilians registered during the 12 months from Jan. 1st to Dec. 31st, 1899, was 12 412; the number of deaths in the army is not made known. Of these deaths 135 were due to diphtheria, 100 to measles, 196 to small-pox, 318 to typhoid fever, and 752 to acute inflammation of the lungs. From Jan. 1st to Dec. 31st, 1900, the number of deaths registered was 12 372, of which 80 were due to diphtheria, 86 to measles, 11 to small-pox, 293 to typhoid fever, and 782 to acute inflammation of the respiratory organs. During the last month of autumn there was a widespread epidemic of scarlet fever but the number of deaths from this cause is not known. The deaths from cholera infantum, or gastro-enteritis in children, were as follows during some of the months of 1900: 11 in May, 89 in June, 107 in July, 74 in August, and 24 in September. If a medical man who understood the value of statistics were at the head of the Bureau de la Mortalité of the Sanitary Board better data would be available for arriving at the death-rate of Constantinople.

Institute for Foundling Children.

On Jan. 13th (Dec. 30th, old style) a number of the destitute children of Pera had their new year fête, when the ladies who assist Dr. Zavitziano in the work of caring for the foundlings of the Greek church in Pera distributed toys and pudding. The institute for the reception of these children has now been established for nearly 12 years and has given very good results, the death-rate being comparatively low. During the epidemic of cholera infantum which prevailed from last June to the middle of September there was no death among them from this cause, a result which is perhaps attributable to the treatment by cold baths.

Murderous Attack on a Medical Man.

It is announced that Dr. Sakellarios (the attempt on whose life was mentioned in THE LANCET of Jan. 12th, 1901, p. 142) is now better and will probably be soon able resume practice.

Medicine under the Greek Emperors.

At two of the last meetings of the Biological Section of the Greek Literary Syllogos, Dr. Gabrielides, ophthalmic surgeon to the French Hospital, delivered two very interesting lectures on General Medicine, Medical Organisation, and Ophthalmology under the Byzantine Empire. He quoted the monk Meletius of Tiberopolis the Great in Lydia, Nemesius the archbishop of Palestine, and Photius the patriarch of Constantinople, the latter of whom makes mention of Oribasius, Aetius, Theon, and other medical writers. Dr. Gabrielides discussed the army medical service of the Empire and referred to the case of the Emperor Andronicus who fell ill with "lethargy" at Dedemoticho and was treated by the ἀρχιάτρος Varys. He also mentioned that Aetius was raised to the rank of nobility with title of Count of Opsikion—Κομῆς τοῦ Ὀψικίου—a place in Bithynia.

Jan. 15th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The United States Soldier's Tropical Ration.

SOME short time ago a board was appointed by the United States Government to report to the Secretary of War upon the tropical ration of the American troops and to recommend changes therein. A board sitting in the Philippines had advised that the fresh-meat ration be reduced in quantity, but in the report of the board recently handed in to the Secretary this suggestion was strongly condemned. The board remarked that the recommendation that the fresh-meat ration be reduced in quantity was so opposed to all the teachings of experience both in the United States and in Cuba and Porto Rico that the board was unable to accept this recommendation as conclusive without further information. As the result of interviewing a number of officers and other persons who had been in the Philippines and taking all sources of information together the board came to the opinion that no fixed reduction should be made in the meat ration. "Any ration adopted must comprise a meat, a bread, a vegetable, a seasoning, and a coffee, sugar, and fruit component, and when a careful comparison is made between the articles now composing these components, and all those suitable for the purpose, it will be readily seen that no important addition can be made to the list, and that, in fact, the articles comprising the ration must be about the same in all climates. The problem is really to find such a ration as will by substitutions among its various ingredients be suitable for all climates. Such a ration should possess the following qualifications: it should be nutritious, sufficient in quantity, easy of transportation, and should consist of as few articles as possible. It should be proof against all climatic changes and susceptible at all times to the greatest flexibility and elasticity, suitable to either the tropics or polar circle, and capable of affording such changes in diet as will be best calculated to preserve the health of the soldier under the conditions surrounding him." The most important change recommended by the board in the diet is that an increased amount of sugar be supplied and that a reduction be made in the fruit supply. There has been for years a very considerable difference of opinion among those persons who have dwelt for any length of time in tropical countries as to what is the most suitable food for white men there. Some contend that a thorough change in diet must be made to preserve good health. Others are as strongly of the opinion that if a white man in the tropics endeavours to live on the same description of food as does the native he will soon lose both energy and strength

Probably the true solution of the difficulty will be found in the happy mean, and by finding out by individual experience what diet is best suited to the climate. So far, however, as soldiers are concerned, in whose case the diet must be more or less a fixed one, the majority of those who have gained experience in Cuba and the Philippines would seem to have reached the conclusion that it would be injudicious to decrease the fresh meat ration.

Yellow Fever in the United States in 1900.

There was no yellow fever reported in the United States during the year 1900 until the month of November, notwithstanding the fact that the disease has prevailed extensively in Rio de Janeiro, in Vera Cruz, and in Havana. In November a few cases were reported in Natchez too late in the season to give rise to much alarm. The preventive measures for 1900 were commenced last winter when a medical officer of the United States Marine Hospital Service was detailed to inspect and report upon the sanitary condition of all the towns of Central America both on the Pacific and Atlantic coasts. At Havana, says the Marine Hospital Service report of Dec. 22nd, 1900, where the disease has prevailed extensively and is still prevailing, the maritime quarantine regulations have been enforced by officers of the service. As a precautionary measure a camp was re-established in Florida. Regarding the cause of yellow fever the findings of the Commission of the Marine Hospital Service, identifying the bacillus icteroides of Sanarelli as the causative agent, have been approved (remarks the report referred to above) by a number of contributed articles in the medical press and have also excited opposing statements. Based upon entire confidence in these findings eight horses are being subjected under the direction of officers of the Marine Hospital Service to immunising inoculations with the view of obtaining a curative and prophylactic serum similar in its action to that for diphtheria. A United States Army Commission, whose members are working at Havana and who have recently published the conclusions they have reached so far, state that judging from the result of experiments conducted by them the bacillus icteroides (Sanarelli) stands in no causative relation to yellow fever, but when present should be considered as a secondary invader in the disease. These statements are wholly conflicting and time alone can prove whether Sanarelli's discovery should be discredited or shall stand as a monument to his fame. The subject of international compact with regard to the sanitation of ports and places habitually infected with yellow fever is still receiving the attention of the Marine Hospital Service, and the Surgeon-General reports so marked an interest and approval of the scheme that it is probable the matter will assume definite form for consideration in the near future.

Physique of Recruits for the United States Navy.

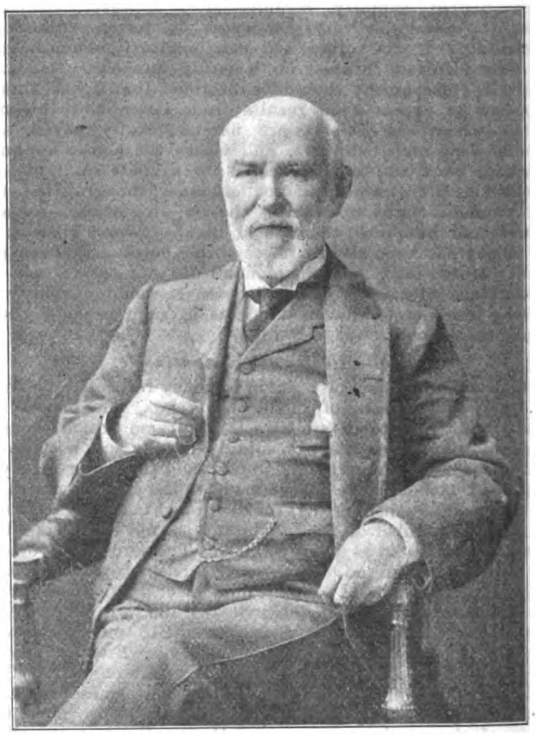
Dr. Edward R. Stitt, assistant surgeon, U.S.A. Navy, writing of the physique of recruits for the navy who came under his notice, states that he was struck by the superiority in physique of those born in the Middle States of North America over the natives of the Atlantic coast. There were noted among the recruits from the Eastern cities a large number of cases of persons who would probably develop unfitness by reason of catarrhal conditions of the throat and nose as well as from relaxation of inguinal rings, these conditions being far less frequent among the recruits from the Western States. While the most striking feature differentiating the two classes was as regards general appearance, yet the following averages, obtained from measurements, are in a degree indicative of this superiority. Of 163 men, natives of the Eastern coast cities, the averages were: age, 20·3 years; weight, 9 st. 3 lb.; height 5 ft. 6 in.; chest expansion, 3·2 inches; circumference of arm, 11 inches; and circumference of thigh. 19 inches. Among those born in the Middle West, numbering 92, the averages were: age, 20·5 years; weight, 9 st. 5 lb.; height, 5 ft. 7 in.; chest expansion, 3·4 inches; circumference of arm, 11·5 inches; and circumference of thigh, 19·5 inches. Of all the 251 recruits enlisted for one ship about a year ago, all coming from the West, the following averages pertained at the time of first examination: age, 21 years; weight, 9 st. 13 lb.; height, 5 ft. 6·6 in.; chest expansion, 3·2 inches; circumference of arm, 11·7 inches; and circumference of thigh, 19·7 inches.

Jan. 14th.

Obituary.

WILLIAM SEDGWICK SAUNDERS, M.D. CASTLETON, U.S.A., M.R.C.S. ENG., L.R.C.P. EDIN.

WILLIAM SEDGWICK SAUNDERS, who passed away on Jan. 18th, was for many years a prominent figure in the City of London. Born in 1824 at Compton Giffard, Devonshire, he was educated at King's College, London, and afterwards at St. Thomas's Hospital, a hospital over which the Corporation of the City of London exercises jurisdiction. After qualifying as M.R.C.S. in 1846 he entered the army as an assistant surgeon and served with the Royal Fusiliers in the West Indies and in North America. Returning to England he served as medical officer to the military prison at Fort Clarence, Rochester, and in 1852 sailed for service in the Kaffir war in the *Birkenhead*. On the way out he was taken seriously ill and had to be landed at the first port of call, a circumstance to which he probably owed his life, for, as will be remembered, the *Birkenhead* caught fire and sank in Simon's Bay with every soul on board of her. On his recovery Dr. Saunders resigned his commission and commenced a private practice in the City. He was soon elected a member of the Court of Common Council and was chairman of the Library Committee, in which capacity he laid the foundation-stone of the Guildhall Library and Museum in



DR. W. SEDGWICK SAUNDERS.

1870. On the retirement of Dr. Letheby, Dr. Saunders was chosen as medical officer of health and public analyst. In both of these capacities he did excellent work, and it is in great part due to the labours of himself and his staff that the City occupies to-day the high position which it does in regard to sanitation. He wrote much on cholera, both on the epidemic of 1866, during which he was medical officer of the City of London Union, and also upon the slight outbreak which occurred in 1893. Other important reports were those on the insanitary condition of St. Bartholomew's Hospital, issued in 1891, and on the insanitary state of Christ's Hospital, issued in 1893, in connexion with an outbreak of scarlet fever. He laboured incessantly to bring

about an improvement in the water-supply of the City and was also much interested in the erection of artisans' dwellings. Apart from his professional career he was a true citizen, being a member of the Broderers' Company and serving the office of Master upon two occasions. He was also a senior member of the Commission of Lieutenancy. A faithful and hard-working servant of the great City which he loved, his death leaves a blank which will be very hard to fill.

EDWARD HODGES CREE, M.D. EDIN., M.R.C.S. ENG., L.S.A.,

DEPUTY-INSPECTOR-GENERAL OF HOSPITALS, R.N.

DR. E. H. CREE, who died at his residence in Upper Holloway on Jan. 16th at the advanced age of 87 years, was in many respects a remarkable man. The first half of his professional life was spent as a surgeon in the Royal navy, in which capacity he served in the first Chinese and Crimean wars. He left the service and set up in practice in Holloway in order that his sons should receive a medical education. They became in succession students of the Middlesex Hospital. Two of them entered the navy, from which the elder son retired to join his father in practice. The other died on board ship from phthisis contracted in the discharge of his duties. Three other sons are at the present time holding commissions in the Royal Army Medical Corps—viz., Lieutenant-Colonel E. R. Cree, now in South Africa; Major G. Cree, at Gibraltar; and Major H. E. Cree, now serving in China. His youngest son is in practice at West Hampstead, whilst the only one of the seven brothers who did not follow their father's profession has been serving in Strathcona's corps in the Transvaal campaign. It is now some years since Dr. Cree himself retired from practice and lived a peaceful life to extreme old age.

Born at Stoke Damerel, Devon, on Jan. 12th, 1814, he was educated at Preston, Lancashire. In 1833, after a five years' apprenticeship to Mr. John Hounsall of Bridport, Devon, he studied at the School of Anatomy, Trinity College, Dublin, and at Edinburgh University. In 1836 he took the L.S.A. and entered the Royal navy as assistant surgeon on June 8th, 1837 After short periods of service in the flagship at Plymouth and at Malta and in the *Firefly* in the Mediterranean he was appointed to the *Rattlesnake* on Sept. 18th, 1839. He went in her to Ceylon and thence to China, where she was engaged in the first Chinese war. On April 4th, 1843, he was transferred to the *Vixen* and remained in her until July, 1846, during her operations against pirates at Borneo. In 1846, after the *Vixen* had returned to England and been paid off, he passed the M.R.C.S. Eng. and also took the opportunity to complete his medical course at Edinburgh University, where he graduated M.D. in 1847. His next ship was the *Fury*, from August, 1847, to December, 1850, serving again in the East Indies and China stations and being present at the destruction of piratical fleets in the Tonquin river (1849). After returning to England he was appointed in December, 1852, to the *Odin* and served in her till May, 1856, in the Baltic, and subsequently in the Black Sea, being present at the fall of Sebastopol. From December, 1856, to February, 1858, he was surgeon of the Coastguard ship at Falmouth, and from October, 1860, to December, 1861, in the *Orion* on the Mediterranean station. This completed his sea service. From September, 1864, to July, 1869, he was staff-surgeon of H.M. Dockyard, Portsmouth, and on July 12th, 1869, he retired from the navy with the rank of deputy-inspector-general of hospitals. During his service he obtained the following war medals: China, Baltic, Crimea, and Turkish.

We have already outlined his subsequent career. Suffice it to add that he gained the confidence and affection of a large circle of patients and passed many happy years in the daily routine of general practice. He was a man of sterling worth, of enlightened ideas, and of high attainments. An artist of no mean order the exercise of his talent enabled him to produce many admirable pictures of the scenes which he had visited during his naval service. His love of art also proved a great solace and source of occupation to him in his latter years when he was freed from the cares of professional life.

CHARLES ROBERTS, M.R.C.S. ENG., L.S.A.

BY the death of Mr. Charles Roberts Uxbridge loses one of its most prominent townsmen. On the morning of Jan. 7th Mr. Roberts, who had only lately taken a house in Belgrave-road, S.W., was waiting at Victoria Station for the Uxbridge train. While talking to the bookstall clerk he suddenly staggered and fell. He was removed to St. George's Hospital but on his arrival he was found to be dead. At the inquest, which was held on Jan. 10th, the house physician at the hospital, gave evidence of receiving the deceased and said that he considered that death had taken place about 15 minutes previously to his admission. Witness had made a post-mortem examination and had found the heart to be fatty while there was atheroma of the aorta. Death was due to syncope. A verdict was accordingly returned of "Death from natural causes." Mr. Roberts, who was born in 1836, received his medical education at St. George's Hospital where he filled the post of house surgeon. He first practised at Dunster, removing to Uxbridge in 1869. In the same year he was appointed divisional surgeon of police, and he also held the post of surgeon to the post office and of medical officer of health of the Uxbridge Rural Sanitary Authority, afterwards the Rural District Council. He took a great interest in the cricket and cycling clubs, and was a prominent member of the Constitutional Club, the Conservative Association, and of the Primrose League. Latterly he had given up his practice except as regards his public appointments. He was buried on Jan. 11th at Uxbridge, the actual burial service being preceded by a celebration of the Holy Communion in the early morning. For over 30 years he had been one of the best known public men in Uxbridge and his decease is very widely felt as a personal loss. Mr. Roberts, who was twice married, leaves a widow and nine children.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—In January the following candidates passed in the subjects indicated:—

Surgery.—S. R. Dudley, St. Bartholomew's Hospital; A. E. U. Hawkes (Sections I. and II.), Liverpool; H. A. Higgens (Section I.), Guy's Hospital; C. G. Meade (Section I.), St. Bartholomew's Hospital; A. U. Parkhurst, Cardiff and St. Mary's Hospital; W. B. Price, St. Thomas's Hospital; F. A. Segreda (Section II.), Guy's Hospital; and A. H. Thomas (Sections I. and II.), and A. J. Watson, (Section II.), St. Mary's Hospital.

Medicine.—S. R. Dudley, St. Bartholomew's Hospital; H. B. Hanson (Section II.), Royal Free Hospital; A. E. U. Hawkes (Sections I. and II.), Liverpool; S. F. Hickman (Section I.), Royal Free Hospital; C. J. Marsh, University College Hospital; L. R. Marshall, St. Mary's Hospital; B. S. O. Maunsell (Section I.), St. Bartholomew's Hospital; S. Page (Section I.), Birmingham; F. M. Payne (Section I.), Royal Free Hospital; E. R. Risien (Section I.), St. Bartholomew's Hospital; F. A. Segreda (Sections I. and II.), Guy's Hospital; and W. C. Spooner (Sections I. and II.), Edinburgh.

Forensic Medicine.—S. R. Dudley, St. Bartholomew's Hospital; A. E. U. Hawkes, Liverpool; F. A. Hort, Middlesex Hospital; B. S. O. Maunsell, St. Bartholomew's Hospital; F. M. Payne, Royal Free Hospital; and W. C. Spooner, Edinburgh.

Midwifery.—H. J. Aldous, King's College Hospital; H. T. Barber, Geneva and St. Mary's Hospital; S. F. Hickman, Royal Free Hospital; R. L. Jones, Middlesex Hospital; C. E. H. Leggatt, St. Mary's Hospital; F. McTavish, Toronto; R. A. Pitter, Middlesex Hospital; F. P. Rose, London Hospital; and P. Southan, Birmingham.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—S. R. Dudley, C. J. Marsh, F. A. Segreda, W. C. Spooner, and A. J. Watson.

UNIVERSITY OF CAMBRIDGE.—Mr. P. V. Bevan has been appointed an Assistant Demonstrator in Physics.—Mr. H. A. Wilson has been elected to the Clerk Maxwell Studentship in Experimental Physics.—At the Congregation on Jan. 17th the following medical and surgical degrees were conferred:—

M.B.—G. O. Lambert, St. John's; S. Bousfield, Caius; H. S. Gabb, Downing; and W. L. Ascherson, non-collegiate.

B.C.—W. E. Moore Ede, King's; N. Maclaren, Trinity; G. A. C. Shipman, Trinity; R. H. Urwick, Trinity; G. O. Lambert, St. John's; H. Edmondson, Clare; L. Wilkin, Pembroke; S. Bousfield, Caius; T. W. S. Paterson, Caius; L. B. Scott, Christ's; A. H. Style, Emmanuel; and H. S. Gabb, Downing.

PROPOSED CONSUMPTION SANATORIUM FOR DEVON AND CORNWALL.—At the meeting of the Sanitary Committee of the Cornwall County Council held on Jan. 18th it was decided to recommend the Cornwall County Council to grant £50 per annum for two years for the support of a bed in the proposed sanatorium for the treatment of tuberculosis.

LUNACY IN DEVONSHIRE.—At the meeting of the Plymouth Board of Guardians held on Jan. 15th it was reported that the accommodation for female lunatics in the borough asylum at Blackadon and also in the workhouse was overtaxed. The guardians passed a resolution urging the corporation to proceed with the extension of the asylum as soon as possible.

LITERARY INTELLIGENCE.—Messrs. Herbert S. Stone and Company, Chicago, announce that they have in preparation, and will shortly issue, a Text-book of Special Surgery, translated from the seventh German edition of Dr. Franz Keenig by Arthur B. Hosmer, M.D., and edited by Christian Fenger, M.D. This is the authorised translation of a well-known German work.

VACCINATION GRANTS.—Mr. J. Dibble Staple, M.R.C.S. Eng., L.S.A., public vaccinator for the Ashley district of the Bristol Union, has been awarded a grant for successful vaccination by the Local Government Board.—Mr. Edward James Sheppard, L.R.C.P., L.R.C.S. Edin., public vaccinator for the Clifton district of the Bristol Union, has been awarded the Local Government Board grant for efficient vaccination for the seventh consecutive time.

THE LATE MR. J. G. SYMES.—Mr. Joseph Gustavus Symes died at his residence, Southfield House, Weymouth, on Jan. 14th, in his seventy-sixth year. The deceased, who was born at Crewkerne, Somerset, was a son of the late Admiral Symes. He received his medical education at St. George's Hospital, London, and qualified as M.R.C.S. Eng. and L.S.A. in 1848. Shortly afterwards he became medical officer at a private asylum near Devizes, Wiltshire, and in 1854 he was appointed medical superintendent of the Dorset County Lunatic Asylum, which post he held for 33 years.

FOREIGN UNIVERSITY INTELLIGENCE.—*Bonn:* Dr. Karl Grouven has been recognised as *privat docent* of Dermatology.—*Breslau:* Dr. Alfred Schaper has been appointed Extraordinary Professor of Anatomy.—*Cadiz:* Dr. Manuel Roca y Bermudo has been appointed Professor of Histology and of Pathological Anatomy.—*Erlangen:* Dr. J. N. Oeller of Munich has been appointed to the chair of Ophthalmology in succession to Dr. Eversbusch.—*Florence:* Dr. G. Mya has been appointed to the chair of Pediatry.—*Freiburg (Baden):* Dr. Adolf Schüle, *privat-docent* of Medicine, has been promoted to an Extraordinary Professorship.—*Geneva:* Dr. Alcide Jentzer has been appointed Professor of Midwifery and Gynæcology in succession to Dr. Vaucher, resigned.—*Göttingen:* Dr. Verworn, Extraordinary Professor of Physiology in Jena, has been appointed to the chair vacated by Dr. George Meissner, who is retiring.—Dr. Boruttau, First Assistant in the Physiological Institute, has been granted the title of professor.—*Gratz:* Dr. Meinhard Pfaundler has been recognised as *privat-docent* of Pediatry.—*Groningen:* Dr. K. F. Wenckebach of Utrecht has been appointed Professor of Clinical Medicine.—*Heidelberg:* Dr. Fürbringer of Jena has been appointed to the chair of Anatomy.—Dr. Kossel of Marburg has been appointed to the chair of Physiology.—*Iurieff (Dorpat):* Dr. Yevetski of Moscow has been appointed Professor of Ophthalmology.—*Jena:* Professor Maurer, who has been prosector under Professor Gegenbaur, has been appointed to succeed his late chief (who has gone to Heidelburg) in the chair of Anatomy. He has done a considerable amount of original work in embryology and comparative anatomy.—*Kiel:* Dr. Theodor Kirchhoff, *privat-docent* of Psychiatry, has been granted the title of Professor.—*Munich:* Dr. Friedrich Voit and Dr. Richard May have been promoted to Extraordinary Professorships of Medicine.—*Palermo:* Dr. Russo-Travali has been recognised as *privat-docent* of Operative Medicine.—*Strasburg:* Dr. Richard Ewald (brother of Professor Carl A. Ewald, Professor of Medicine) has been appointed to succeed Dr. F. Goltz who is retiring from the chair of Physiology.—Dr. Hermann Fehling of Halle has been appointed to the chair of Midwifery and Gynæcology in succession to Dr. Freund, resigned.—*Tübingen:* Professor Robert Wollenberg of Hamburg has been appointed to the chair of Psychiatry as successor to Dr. Siemerling.—*Vienna:* Dr. Richard Paltauf has been appointed Professor of General and Experimental Pathology in succession to the late Dr. Knoll.—Dr. V. Hammerschlag has been recognised as *privat-docent* of Otology.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

ALLEN, H., L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer, Crediton Union, vice G. A. H. Barton, resigned.

BARTLETT, T. W., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed District Medical Officer, Halstead Union, vice R. Reynolds.

BRADFORD, W. G. H., M.B., B.C. Camb., has been appointed District Medical Officer, Bosmere and Claydon Union, vice D. M. French, resigned.

BRIGSTOCKE, C. A., M.R.C.S., has been appointed Certifying Surgeon under the Factory Acts for the Haverfordwest District in the County of Pembroke.

COLEMAN, E., M.B., B.S. Lond., L.R.C.P., M.R.C.S., has been appointed District Medical Officer, Sleaford Union, vice J. H. Pim, resigned.

DODD, HENRY NOEL N., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Assistant House and Visiting Surgeon to the Stockport Infirmary.

FIELD, R. C., M.B. Lond., has been appointed District Medical Officer, Patrington Union, vice E. Robinson, resigned.

FOX, G. A. T., L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer, Dore Union, vice T. C. Lawson, resigned.

HARDY, C. M., M.B., B.S. Durh., has been re-appointed Medical Officer of Health by the Croft Rural District Council.

HOLMES, THOS., M.B. Lond., has been appointed District Medical Officer, Lancaster Union, vice G. R. Parker, resigned.

HOWDEN, ROBERT, M.A. Durh., M.B. Edin., F.R.S.E., has been appointed Examiner in Anatomy in the University of Edinburgh.

HUEY, J. J., L.S.A., has been appointed District Medical Officer, Doncaster Union, vice B. Sweeten, resigned.

JACKSON, H. W., M.D. Lond., D.P.H., has been appointed District Medical Officer, Middlesborough Union, vice A. Webster, deceased.

MACKENZIE, JOHN, L.R.C.P. & L.R.C.S. Edin., has been appointed District Medical Officer and Public Vaccinator for Ingleton, Thornton-in-Lonsdale, and Burton-in-Lonsdale, Settle Union, vice F. A. Griffiths, deceased.

MCLAREN, T. D., M.B., C.M. Edin., has been appointed District Medical Officer, Mitford and Launditch Union, vice E. R. McDonnell, resigned.

MONTGOMERIE, HUGH MAYER, M.D., C.M. Edin., has been re-appointed Physician to the West Cornwall Infirmary, Penzance.

MONTGOMERY, JAMES BARCLAY, M.D. Glasg., L.R.C.P. Lond., M.R.C.S., J.P., has been re-appointed Honorary Consulting Physician to the West Cornwall Infirmary, Penzance.

OYSTON, W. F., M.B., Ch.B. Vict., has been appointed District Medical Officer, Northallerton Union, vice J. Clark, resigned.

PARRY-JONES, MAURICE, M.D., B.S. Lond., M.R.C.S., has been appointed Honorary Physician to the Derbyshire Royal Infirmary.

RIVIÈRE, CLIVE, M.D. Lond., M.R.C.S., M.R.C.P., has been appointed Pathologist and Registrar to the East London Hospital for Children and Dispensary for Women, Shadwell, vice Thomas D. Lister.

ROBERTSON, WILLIAM, M.D. Glasg., D.P.H., has been appointed Medical Officer of Health for Leith.

SMITH, R. R., L.R.C.P., L.R.C.S. Irel., has been appointed District Medical Officer, West Derby Union, vice J. J. Flinn, resigned.

SYMONS, JOHN, M.R.C.S., L.S.A., J.P., has been re-appointed Surgeon to the West Cornwall Infirmary, Penzance.

THOMPSON, PETER, M.D. Vict., has been appointed Lecturer on Anatomy at the Middlesex Hospital Medical School.

WILKINSON, W. A. H., M.B., Ch.B. Vict., has been appointed Medical Officer of Health, Gainsborough Urban District.

WILLCOX, W. H., M.B., B.Sc. Lond., D.P.H., A.I.C., has been appointed Lecturer on Chemistry and Physics at St. Mary's Hospital Medical School, Paddington. London, W.

YOUNG, C. W., L.R.C.P. Lond., M.R.C.S., D.P.H. Camb., has been appointed District Medical Officer, Luton Union, vice W. Duncan, resigned.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BIRMINGHAM CITY FEVER HOSPITAL, Lodge-road.—Assistant Medical Officer. Salary £120 per annum, with board, residence, &c.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Assistant House Surgeon. Salary £60 per annum, with apartments and board.

BOLTON INFIRMARY AND DISPENSARY.—Senior House Surgeon. Salary £120 per annum, with furnished apartments, board, and attendance.

BRADFORD ROYAL INFIRMARY.—Dispensary Surgeon, single. Salary £100 per annum, with board and residence.

CENTRAL LONDON SICK ASYLUM DISTRICT.—First Assistant Medical Officer (salary £100 per annum) and Second Assistant Medical Officer and Dispenser (salary £75 per annum), each with board and residence.

CHORLTON-UPON-MEDLOCK DISPENSARY, Manchester.—Resident House Surgeon, unmarried. Salary £130 a year, with furnished rooms and attendance.

DONCASTER GENERAL INFIRMARY AND DISPENSARY.—Assistant House Surgeon, unmarried. Board and residence provided.

GENERAL HOSPITAL, Nottingham.—House Physician for two years. Salary £100, rising £10 a year to £120, with board, lodging, and washing.

GUEST HOSPITAL, Dudley.—Senior Resident Medical Officer. Salary £100 per annum, increasing £10 a year to £120, with board, residence, attendance, and washing.

GUY'S HOSPITAL MEDICAL SCHOOL.—Gordon Lectureship in Experimental Pathology.

HOSPITAL FOR WOMEN, Soho-square, London, W.—Assistant Physician, also Assistant Surgeon.

LEEDS GENERAL INFIRMARY.—House Physician for six months. Board, lodging, and washing provided.

LEEDS UNION, East Parade, Leeds.—Assistant Medical Officer, single, not above 35, for Workhouse, Schools, and Infirmary. Salary £130 per annum, rising £10 annually to £150, with board, washing, apartments, and attendance (subject to deduction under the Poor-law Officers' Superannuation Act, 1896).

LINCOLN HOSPITAL FOR INSANE.—Locum Tenens for six weeks from about 6th of February. Three guineas a week.

LIVERPOOL DISPENSARIES.—Assistant Surgeon. Salary £100, with board and apartments.

LIVERPOOL STANLEY HOSPITAL.—Junior House Surgeon. Salary £70 per annum. Also Third House Surgeon as Ambulance Surgeon. Salary £70 per annum, with board, residence, and washing.

MIDDLESEX HOSPITAL, W.—Assistant to the Bacteriologist. Salary £80 per annum.

MILLER HOSPITAL and ROYAL KENT DISPENSARY, Greenwich-road, S.E.—Junior Resident Medical Officer, tenable for six months, with prospect of re-election as Senior. Salary at the rate of £60 per annum, with board, attendance, and washing.

NORFOLK AND NORWICH HOSPITAL, Norwich.—Resident Secretary and House Steward, twenty-eight to forty five years of age, with previous hospital experience. Salary £150 per annum, rising £10 yearly to a maximum of £200, with apartments, board, and laundry.

NORTH DEVON INFIRMARY, Barnstaple, Devon.—House Surgeon. Salary £80 per annum, with board, residence, and washing.

NOTTINGHAM GENERAL DISPENSARY.—Assistant Resident Surgeon. Salary £140 per annum, all found except board.

OLDHAM INFIRMARY.—Senior House Surgeon. Salary £100 per annum, with board, residence, and washing.

PADDINGTON-GREEN CHILDREN'S HOSPITAL, London, W.—Pathologist.

ROXBURGH DISTRICT ASYLUM, Melrose, N.B.—Assistant Medical Officer. Salary £110, rising to £120 per annum, with board, lodging, and washing.

ROYAL SEA-BATHING HOSPITAL, Margate.—Assistant Resident Surgeon. Salary £52 per annum, with board and residence.

RURAL DISTRICTS OF BUNTINGFORD, &C., AND CERTAIN URBAN DISTRICTS.—Medical Officer of Health. Salary £600 per annum, including travelling and all other expenses.

ST. BARTHOLOMEW'S HOSPITAL, Rochester.—House Surgeon, Salary £120 per annum, with board, lodging, washing, firing, and light.

SEAMEN'S HOSPITAL SOCIETY.—Senior Dental Surgeon and also Junior Dental Surgeon. No salary, but first-class railway fare between London and the Hospitals will be allowed.

STOCKPORT INFIRMARY.—Junior Assistant House Surgeon for six months. Salary at the rate of £24 per annum, with board, washing, and residence.

THE CHIEF INSPECTOR OF FACTORIES gives notice of vacancies for Certifying Surgeons under the Factory Acts at Totnes, in the County of Devon; at Broughton, in the County of Hants; at Uxbridge, in the County of Middlesex; at Bangor, in the County of Carnarvon; and at Cerrig-y-Druidion, in the County of Denbigh.

UNIVERSITY OF ST. ANDREWS.—Examiner for Graduation in the subject of Physiology.

WEST BROMWICH DISTRICT HOSPITAL.—Resident Junior House Surgeon. Salary £50 per annum, with board, lodgings, washing, and attendance.

WESTERN GENERAL DISPENSARY, Marylebone-road.—Second House Surgeon, unmarried. Salary £75 per annum, with 10s. per month for washing, and board and residence.

WEST HAM HOSPITAL, Stratford, E.—Junior House Surgeon for one year, eligible for election to the post of Senior House Surgeon for a further year. Salary as Junior £75 per annum, with board, residence, &c.; as Senior £100.

Births, Marriages, and Deaths.

BIRTHS.

NUTTALL.—On Jan. 17th, at 18, Clough-street, Bury, Lancs., the wife of A Peel Nuttall, M.D. Lond., of a daughter.

RICHARDSON.—On Jan. 22nd, at Kirkstall, Alverstoke, Hants, the wife of Dr. Martin Richardson, of a daughter.

MARRIAGES.

NEWTON—GRAY.—On Dec. 27th, at Marylebone Presbyterian Church, Upper George-street, W., by the Rev. George Hanson, M.A., D.D., Duncan Gray Newton, M.B., C.M. Edin., Brook-hill, Sheffield, to Janet Mackinnon, daughter of the late Archd. Gray and Mrs. Gray of 37, Holland-park, W.

DEATHS.

KEMP.—On the 2nd of Jan., 1901, at Lewes, G. T. R. Kemp, M.D., late of Nassau, New Providence, Bahamas, aged 68 years.

MYERS.—Died at Pará, Brazil, January 20th, 1901, Walter Myers, M.A., M.B. Cantab., only son of George and Flora Myers, 166, Hagley-road, Birmingham, of yellow fever, contracted whilst working for the Liverpool Tropical School of Medicine, in his twenty-ninth year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

DEATH AND QUACKERY.

ON Jan. 18th Mr. R. J. Rhys held an inquest at the Merthyr General Hospital upon the body of William John Lewis, a repairer, who died in the hospital on Jan. 15th. A short reference to this case will be found in a letter from our Welsh correspondent. William Richards, a friend of the deceased, said that they were together on Dec. 22nd. Witness was carrying a four-gallon cask of beer and as he was shifting it to the shoulders of Lewis the cask slipped and fell on to the foot of the deceased. In answer to the coroner witness said that they were not sober but were not drunk. John Lewis, father of the deceased, said that he saw his son's foot on the day following the accident and that then it had a nasty look. On Dec. 24th the deceased went to see Mr. Price, the bone-setter of Pontmorlais. He went again on the two following days, and then as the toe got no better he stopped his visits and the toe was poulticed at home. Mr. Price then took to visiting the deceased at his own home and gave him ointment and oil, and Price and his son-in-law, a man named Davies attended the deceased until his admission to the hospital on Jan. 12th. Mr. P. F. James, assistant to Mr. T. J. Webster saw the deceased about a week after the accident and recommended his removal to the hospital, saying that amputation of the toe should be performed, and warning the parents of the deceased of the danger of blood-poisoning. Deceased worked in the Cwmdu drift and paid in to the "works doctor," but he had faith in Price. Mr. T. J. Webster, surgeon to the Merthyr General Hospital, gave evidence of seeing Lewis on the morning of his admission. The left big toe was smashed and gangrenous, and the lymphatics and veins of the leg were implicated. There was an abscess above the ankle and effusion into the left shoulder-joint. On Jan. 14th the deceased developed pleurisy and he died on Jan. 15th simply from blood-poisoning. The gangrene was not brought on by the ointment and oil, but the case was not treated an tiseptically in any way. Price and Davies gave evidence and detailed how they had treated the case, Davies adding that he had advised the parents to call in a medical man on Jan. 10th because then the patient was "suffering with his body as well." Mr. James gave evidence of seeing the deceased and of recommending his removal to hospital about a week after the accident. The coroner in summing up expressed himself very strongly that the treatment of Price and Davies was nothing but botching. He continued, according to the report in the *Western Mail* of Jan. 19th:—

> Neither of these men was competent to take charge of such a case. If it had been a case of a simple burn he should not have thought very much of it, but when it was a case of a fracture of the toe he thought that in meddling with it Price and Davies were very much to blame. These bone-setters were absolutely irresponsible people, and he considered they did a good deal of mischief. He was continually hearing of cases in which they made a terrible mess of patients. Not long ago he had a case at Hirwain where a man who had been injured underground was mauled about by some person who was called in from Merthyr, in a most shameful way about three days before he died. It did not appear to him that this was a case which amounted to manslaughter, but, at the same time, he could not help expressing the opinion that this poor man's life had been allowed to slip away between this precious couple, Price and Davies. He firmly believed that if a properly qualified doctor had attended the case at the commencement there would have been a very good chance, indeed, of the man being still alive. It was monstrous for people to pay to the works doctor and not to avail themselves of his services. A man's life was of some value to others besides himself, and if he were injured it was his duty to do the best he could to recover. He did not do the best he could to recover if, instead of going to a doctor he went to someone who was nothing more than a quack.
>
> The jury, after a short consultation in private, returned a verdict in accordance with Mr. Webster's evidence.

We have quoted the coroner's remarks because they are so excellent that we can really add nothing to them. It is perfectly inexplicable to us how miners, men who are a very shrewd, hard-headed class, should be so fond of being treated by bone-setters and other quacks. However, as the law stands, if anyone is fool enough to consult such people there is nothing to stop them from practising.

ACCOMPLISHED BATH ATTENDANTS.

ABOUT a year ago the question was raised in a coroner's court at Manchester as to what proportion of the attendants in the Manchester baths were competent to give aid to the apparently drowned. The son of a well-known philanthropist—the late Mr. Thomas Wright—was found unconscious in one of the private baths. In this case the attendant was able to give first aid, but without success. The coroner suggested that all the attendants at all the public baths of the city should be made similarly competent. The Baths Committee took the question up. All the male and female attendants were supplied with

copies of the National Life Saving Society's Handbook, with special suggestions that they should study the Sylvester method, and they were drilled from time to time by a past secretary and examiner of the society. This gentleman has reported the result of the exhaustive examination which he has made as regards the knowledge of the attendants and their skill in using the means of resuscitation. This examination comprised a practical demonstration of the steps necessary for restoring breathing and the reasons for the various movements. Each attendant was made to act in turn the parts of operator, assistant, and patient, and each one of them is stated to be "competent to render assistance to an apparently drowned person until the arrival of medical help." Charts are exhibited in prominent positions in the various baths showing the method of life saving, so that bathers may learn if they wish. This is certainly to the credit of the Baths Committee and it would be well if all the public baths in the country had an equally skilled staff of bath attendants.

CHRONIC DIARRHŒA; SUGGESTIONS FOR TREATMENT DESIRED.

To the Editors of THE LANCET.

SIRS,—I shall be obliged if any of your readers can help me in prescribing for the following case. A man, aged 60 years, has been the subject of chronic diarrhœa for the past 12 months, blood very frequently appearing in the stools. He has not lost flesh and his appetite remains good. I have given him opium, bismuth, chalk, quinine, and a host of other remedies commonly employed, but with no avail.

I am, Sirs, yours faithfully,

Jan. 21st, 1901. PERPLEXED.

AN ARTIFICIAL SPONGE.

WE have received from Mr. C. Hamilton Whiteford of Plymouth a specimen of an artificial sponge which he has devised. It is composed of "camel-hair blanketing" covered with buttercloth. He claims for it the following advantages: (1) easy sterilisation by boiling; (2) great power of absorption; (3) elasticity, with soft, smooth surface; and (4) cheapness, as the materials for each sponge cost 2½*d*. With the justice of most of these claims we agree, as we have tried the specimen sent to us, pointing out, however, that its power of absorption is certainly less than that of a good sea sponge. It is likely to prove useful in certain cases, as, for instance, when a large, smooth, flat surface is desired. As to the price, the cost must necessarily be decidedly higher than the cost of the material.

WANTED—A HOME.

To the Editors of THE LANCET.

SIRS,—I should be much obliged if you or any of your numerous readers could tell me of a home for a little boy, aged six years, suffering from Friedreich's palsy, and if possible the annual cost.

I am, Sirs, yours faithfully,

JOHN TAYLOR, M.D. Edin.

Ivy Cottage, Rhymney, *vid* Cardiff, Jan. 16th, 1901.

"THE INCOME-TAX REPAYMENT AGENCY."

To the Editors of THE LANCET.

SIRS,—At this time of the year you have always allowed us to inform your readers of the refunds of income-tax to which they may be entitled. This year the refunds are greater because the rate of tax is much higher. We would call particular attention to the fact that it will soon be too late to claim a return of tax for the year 1897-98. Claims can be made as follows: For the year ended April 5th, 1898, for a refund of (*a*) the whole tax paid or deducted if the income did not exceed £160; (*b*) £5 6*s*. 8*d*. if the income exceeded £160 without exceeding £400; (*c*) £3 6*s*. 8*d*. if the income exceeded £400 without exceeding £500. For each of the years ended April 5th, 1899 and 1900, for a refund of (*a*) the whole tax paid or deducted if the income did not exceed £160; (*b*) £5 6*s*. 8*d*. if the income exceeded £160 but did not exceed £400; (*c*) £5 if it exceeded £400 but did not exceed £500; (*d*) £4 if it exceeded £500 but did not exceed £600; (*e*) £2 6*s*. 8*d*. if it exceeded £600 but did not exceed £700. For the current year to April 5th, 1901: (*a*) the whole tax paid or deducted if the income does not exceed £160; (*b*) £8 if the income exceeds £160 without exceeding £400; (*c*) £7 10*s*. if it exceeds £400 without exceeding £500; (*d*) £6 if it exceeds £500 without exceeding £600; (*e*) £3 10*s*. if it exceeds £600 without exceeding £700. The refund for the four years may thus amount to £24 or to double that amount in case of separate assessment of husband and wife. Claims for four years can still be made on life insurance premiums. A claim for one year can be made on decreased profits from profession, trade, or farming, also for any loss made during the past year, the refund being claimed out of the tax paid on other sources of income. We would call attention to the fact that income-tax can be recovered on rent of property and on dividends said to be paid free of tax.

We are, Sirs, yours faithfully,

THE INCOME TAX REPAYMENT AGENCY.

Chichester-road, Paddington, London, W., Jan. 16th, 1901.

Surgeon writes:—"Does the time a medical officer has passed on retired pay count if required to serve again as 'continuous service towards' an increase of service on again reverting to retired pay? And are officers who have been called upon to volunteer their services in time of war placed on the same footing as if they had actually been recalled? Also are they eligible for further promotion?"

Disgusted has, we think, a very real grievance. We will grant at the outset that he was unduly trustful in sending the originals of his testimonials. Copies should always be sent; if it is necessary for the presumptive employer to see the originals they can be exhibited at a personal interview. Photographs, as our correspondent says, cost money, and common honesty, to say nothing of courtesy, demands the return of both photographs and of testimonials. There are generally many applications for one post, only one man can be successful, and it is the undoubted right of those who are not successful to have the documents returned to them which are necessary for their application for another post. Of course, if an advertiser should state that testimonials and photographs will in no case be returned he is freed from the obligation of returning them, but if no such statement is made they should without doubt be sent back.

Asterion.—1 and 2. The Home Secretary appoints the medical officers of the prison service. 3. The medical visitors of lunatics are appointed by the Lord Chancellor and the Commissioners in Lunacy by the Crown.

Inquirer.—It is not our custom to receive such advertisements.

ERRATUM.—In Dr. Ninian Falkiner's letter on "Arsenic and Aerated Waters" in THE LANCET of Jan. 19th, page 213, line 13, the word "organism" ought to be *arsenium*.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

SOCIETIES.

MONDAY (28th).—ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (20, Hanover-square. W.).—7 P.M. Council Meeting. 8 P.M. Casual Communications:—Mr. C. Schelling: An Obscure Case elucidated by means of the X-rays.—Mr. H. B. Dowsett: A Dental Cyst arising from the Root of a Living Tooth. Paper:—Mons. J. Choquet: The Non-Specificity of the Micro-organisms of Dental Decay (with lantern illustrations).

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Discussion on the Treatment of Typhoid Fever (opened by Dr. F. J. Smith).

WEDNESDAY (30th).—BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Discussion on Anæmia and its Therapeutics (opened by Prof. C. Allbutt).

THURSDAY (31st).—OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8 P.M. Cases. 8.30 P.M. Papers:—Dr. G. A. Berry: (1) On so-called Paresis of Divergence; (2) Note on Two Rare Forms of Non-paretic Non-concomitant Squint.—Dr. R. D. Batten: "Eclipse Blinding" with Choroido-retinitis and Obstruction of a Retinal Artery.—Mr. A. Critchett: A Case of Bullet Injury of Occipital Lobes with Loss of Lower Half of each Visual Field.—Dr. Edridge-Green: Evolution of the Colour-sense.

FRIDAY (1st).—LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—5 P.M. Cases and Specimens will be shown by Sir Felix Semon, Dr. Bronner, Dr. Wingrave, Dr. Donelan, Mr. Waggett, and others.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith-road, W.).—8.30 P.M. Discussion on the Feeding of Infants in Health and Disease.

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich-road, S.E.).—8.45 P.M. Paper:—Mr. E. Clarke: The Diagnosis and Treatment of Corneal Affections (illustrated by a number of typical clinical cases). Special General Meeting. In accordance with a requisition signed by five members the Council (under Rule 23) hereby summons a Special General Meeting, to be held at the Royal Dispensary at 8 P.M. on Friday, Feb. 1st, 1901, to consider a proposed addition to the rules enabling the Society to deal with the expulsion of a member legally convicted of any criminal offence involving imprisonment, or complained against for grossly unprofessional conduct.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c

MONDAY (28th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. J. Galloway: Consultation. (Skin.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. H. P. Dunn: Cataract.

TUESDAY (29th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. J. Taylor: Consultation. (Medical.)

WEDNESDAY (30th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. R. Harrison: Consultation. (Surgical).

THURSDAY (31st).—CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL (Gray's Inn-road, W.C.).—5 P.M. Dr. D. Grant: Treatment of Inflammatory Affections of the Pharynx and Larynx.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. J. Hutchinson: Consultation. (Surgical.)

CHARING-CROSS HOSPITAL.—4 P.M. Dr. Bruce: Medical Cases. (Post-graduate Course.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. Saunders: Arsenical Neuritis.

FRIDAY (1st).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. D. Grant: Consultation. (Throat.) 5–7 P.M. Mr. J. Griffith: Class: The Use of the Ophthalmoscope and Refraction.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1900, which was completed with the issue of Dec. 29th, and the Title-page to the Volume were given in THE LANCET of Jan. 5th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1900, bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers, cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Office, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND

During the week marked copies of the following newspapers have been received: *Springburn Gazette, Wiltshire Advertiser, Ilford Guardian, Chronicle (West Bromwich), Birmingham Daily Gazette, Manchester Courier, Bath Advertiser, Hereford Times, Guardian (Preston), Scotsman, Surrey Times, Plymouth News, Ealing Times, Rugby Advertiser, Norfolk News, Times of India, Pioneer Mail, Essex Times, Grimsby Express, Bolton Chronicle, Builder, Citizen, Architect, Elgin Courant, Walsall Advertiser, Yorkshire Post, Market Harborough Mail, York Daily Herald, Keighley News, Liverpool Daily Post, Dundee Advertiser, Leeds Mercury, Kent Messenger, Bristol Mercury, Daily Telegraph, Aberdeen Journal, Rangoon Times, Montreal Gazette, Huddersfield Examiner, Ulster Echo, Hertfordshire Mercury, Local Government Chronicle, Reading Mercury, Mining Journal, City Press, Oban Times, Croydon Advertiser, Orkney Herald, Belper Chronicle, West Australian, Surrey Advertiser, Birmingham Daily Post, Local Government Journal, Outlook, &c., &c.*

Communications, Letters, &c., have been received from—

A.—Association for Vaccine Lymph, Lond.; Anthropological Institute, Lond.; Messrs. Armour and Co., Lond.: A. B. H.; Messrs. Allen and Hanburys, Lond.; Mons. J. Astier, Asnières, France.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded,

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France,—J. ASTIER, 8, Rue Traversière Asnières, Paris.

The Baillie Lectures

ON

CONSIDERATIONS TOUCHING THE PATHOLOGY AND RELATIONS OF DIABETES.

Delivered at St. George's Hospital on Dec. 5th and 12th, 1900,

BY W. HOWSHIP DICKINSON, M.D. CANTAB., F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET; HONORARY FELLOW OF CAIUS COLLEGE, CAMBRIDGE.

LECTURE I.

Delivered on Dec. 5th, 1900.

GENTLEMEN,—In seeking for a topic for the Baillie Lectures it occurred to me that I might find something to say about diabetes mellitus both in retractation and reassertion. It would be difficult to light upon any disease which is more distinct clinically, or of which the pathology is more obscure. Not that we know nothing about it. We can with some confidence associate an infrequent form of diabetes with disease of the pancreas. As to the variety of more ordinary occurrence, though we know enough to indicate with probability that the organic seat of the disorder is in the nervous system, yet we are not able to discern the special centre of the mischief, the *fons et origo mali*, nor can we say to any pathologist *rem acu tetigisti*. The needle of Claude Bernard can make a rabbit glycosuric, and something of the kind has been observed in the human subject; but the way of disease is less simple or more minute, nor can we as yet work out the analogy between experimental and human pathology. Much is left for the future. We are conscious that we do not see everything and are well assured that there is much to be seen that has not yet come within our discernment. Indeed, so recent is minute or microscopic pathology as compared with medicine that the wonder is that we have found out so much rather than that we have not found out more. To call a disease "functional" is generally a confession of ignorance. In medicine we must all be materialists and must seek structural change as at the bottom of every persistent perversion of action that is not accounted for by as persistent a perversion of external influences.

The nineteenth century has witnessed greater progress in the science of disease—in other words, in pathology—than all preceding time, and in no department has the progress been more remarkable than in diseases of the nervous system. We no longer talk of serous apoplexy as a frequent cause of death but of uræmia, embolism, or thrombosis. Many lesions which our forefathers knew not of or recognised only by their symptoms have become definite and tangible. Syphilis as affecting the nervous system has become amenable both to observation and treatment. As to essential paralysis, what is now known to be essential is not the paralysis but the mischief in the anterior horns which has caused it. Tetanus is no longer vaguely attributed to nervous irritation but is definitely traced to special and living organisms introduced from without. It has been shown that chorea is accompanied with substantial changes in the cord which, though they do not reveal the pathological starting-point, suffice to show that the relation of the arteries to their surroundings is largely and roughly abnormal. What may be said about chorea applies equally to other diseases of the nervous system, among which we cannot hesitate to place the ordinary form of diabetes.

In all that relates to the ultimate morbid anatomy and fundamental pathology of the nervous system it must be suspected that what we now know is as nothing compared to what the next century will reveal. But we have already seen enough to be able to infer that there is more to be seen. The knowledge of the minute morbid anatomy of the nerve-centres scarcely dates beyond the introduction of methods of hardening which is within the memory of many who do not think themselves senile. In the examination by new modes of a substance so unstable as the tissue of the brain and cord errors were at first inevitable; nor can I claim exemption from the common lot. Post-mortem changes have been supposed to be of ante-mortem origin. Isolated spots refusive of carmine, the results of faulty preservation, have been supposed to indicate degeneration during life and have received the name of "miliary sclerosis." And too much importance was attached in early days to certain appearances of erosion and degeneration about the perivascular canals, which, however produced, were too common to indicate vital change, or at least change of vital importance.

I propose to review the morbid anatomy of diabetes in the light of our present knowledge, excluding everything to which doubt can attach and all appearances which admit of any interpretation other than as the results of living and morbid processes. It must be acknowledged that no constant change has yet been recognised such as would serve to define the disease in terms of morbid anatomy as pneumonia is defined by hepatisation of the lung. The most frequent morbid appearance found in connexion with diabetes is extravasation of blood in the perivascular canals of the brain, not limited to, or constant to, any one part, but scattered apparently at random around the deeper arteries which, microscopically speaking, are of considerable size and also in connexion with the more minute vessels of the pia mater. These extravasations are not the results of rupture, but of transudation, leakage through healthy vessels, implying, if nothing else, that the internal pressure is too much for the parietal resistance. It may be observed in passing that the extravasations in question have no necessary connexion with the coma of diabetes and the disturbance of cerebral circulation which may be supposed to ensue upon it but are found as often as not without the intervention of this possible cause of intravascular disturbance. An instance of the hæmorrhage in question which is displayed by one of the preparations on the table and also by the drawing which I show[1] was found in connexion with some vessels, apparently arterial, in the median line above the fourth ventricle. The vessels, comparatively small ones, were thickly embedded in blood which retained its corpuscular structure. I reproduce some other illustrations which show the blood outside instead of inside its proper vessels, a state of things which, whether peculiar to diabetes or not, must be regarded as undoubtedly abnormal.

I have before me preparations taken from 22 diabetic brains; eight of them display perivascular hæmorrhages—blood in a recent state outside the vessels. Some of these instances were striking, even conspicuous, like those which have been selected for representation. Such hæmorrhages are not essential to diabetes, but they cannot fail to indicate an abnormal condition of the cerebral circulation which is thus declared in more than a third of the fatal cases. This statement takes no account of blood crystals but only of blood in a recent state and, microscopically speaking, in bulk. Still, to limit myself to the brain, other signs and results of morbid action are found in connexion with the perivascular canals. One of these, which is conspicuous as well in the recent state as after hardening, is enlargement of groups of these channels which gives to certain districts of the white matter a cribriform appearance. This is frequent and obvious in diabetes but not peculiar to it. Whether it is the result of distension of the canals or shrinkage of the intervening substance it is occasionally to be recognised in other conditions. I have seen it conspicuously in chronic disease of the brain attended with mental failure and in a less degree where its pathological association was less evident. Beside this cribriform dilatation the spaces about the more considerable vessels appeared in some instances to be enlarged and presented contents which could not but be regarded as abnormal. I have a drawing which was published in the Transactions of the Royal Medical and Chirurgical Society which shows an artery within the corpus denticulatum encrusted with a thick sheath of disorganised nerve-tissue. In other cases leucocytes and amorphous matter were found in these canals, and often blood-crystals in unusual multitude. We see, therefore, in the brain a widely scattered disturbance of the relation between the arteries and their surroundings, not always in the same place nor to the same extent, but significant of morbid action. Though we have not found out the

[1] This preparation and some others here referred to are represented in my work on "Renal and Urinary Affections, vol. i., pages 35, 36, 37, and 38.

initial source of the disturbance we cannot but suspect the vaso-motor centre as holding the key of the mystery.

Proceeding to the cord I may refer to an appearance which, though only occasional, is not without significance. I allude to dilatation of the central canal, which has received the name of syringomyelia. I have before me preparations of eight diabetic cords, in two of which the condition in question is fully displayed. The dilatation in both was conspicuous to the naked eye and admitted of no doubt as to its pathological origin. In a third instance the evidence of dilatation escaped my notice until my attention was called by Professor Woodhead to a puckered state of the walls of the canal as if contraction had succeeded upon dilatation. The dilatation was probably caused by effusion into the canal connected with hyperæmia. It is worth noting that similar dilatation has been observed in other diseases. I have recognised and described a striking development of this condition in chorea.[2] There is reason to believe that it may be either congenital or acquired; if acquired, as it presumably is when in connexion with disease, it appears to be associated with hyperæmia and exudation.

Certain of the diabetic cords (three out of eight) presented a peculiar hyaline modification of the lateral parts of the grey horns which I have represented elsewhere.[3] Renewed examination has, however, led me at least to entertain the probability that this local change, limited as it was to the deeper parts of the structure, may not have been wholly unconnected with post-mortem change. There were, indeed, some unequivocal evidences of morbid action, particularly in the shape of vascular engorgement, but the translucency of the grey matter, limited as it was to the deeper parts, admitted of doubt. I have referred the sections in question to an eminent pathologist and to an eminent neurologist. One considers the negative change as morbid, the other as post mortem. I incline myself to the latter opinion, and therefore rest no argument on the so-called sclerosis.[4] Since my observations were made Dr. R. T. Williamson has published two cases of diabetes with evidences of degeneration of the posterior columns. These consisted of change of colour, swelling of the nerve-fibres, and proliferation of the connective tissue. These local alterations were supposed by Dr. Williamson to resemble in place and character the degenerations found to follow experimental section of the cord and were hypothetically attributed to the action of the toxic blood. This explanation, however, does not explain the limitation of the change to the posterior columns. Dr. Williamson found what he has described in two out of five cases examined.

In reviewing the morbid anatomy of diabetes we must, in the first place, have regard to the fact that we have to do with a structure which is prone to rapid alteration as soon as the antiseptic influence of life is removed and, in the next place, make due allowance for the effect which saccharine blood has upon certain tissues lest we associate with the origin of the disease changes which are its consequences.

Next to the brain the liver calls for consideration as supplying an early, though probably not the initial, step in the diabetic process. None of the recognised diseases of the liver, such as cirrhosis, cancer, or abscess, are connected with diabetes; nevertheless, the diabetic liver presents certain characteristics which differ from those of health and which suffice to show that this organ is in some way involved in the disturbance. The organ is large, hard, red, and congested. The vessels are full of blood and have been known to present coagulation both in the arteries and veins which is open to question as having formed after death or shortly before it, but which in either case implies an abnormal fulness of the vascular system. I have published as an instance of ante-mortem coagulation in the disease in question a drawing of a section of a diabetic liver in which both the portal vein and the hepatic artery contain clot.[5] I need not say that after death the arteries are usually empty, while for the veins to hold their contents *in situ* after the organ is cut into small pieces very complete coagulation must have taken place before the post-mortem examination. On the other hand, it is clear that if the clotting occurred before death it was not long before, for the clot shows no sign of morbid action. Whenever the coagulation occurred, especially in the arteries, it must be taken as indicating an abnormal fulness of the vessels.

It is not always easy to decide between ante-mortem and post-mortem changes. This remark applies not only to coagulation in the vessels, but also to a condition of capillary dilatation about which I was long in doubt. I thought formerly that the evidence was in favour of this having occurred during life; I now have come to the conclusion that the greater probability is on behalf of its having been created after death by the development of gas in the tissue as the result of decomposition.

I do not propose to dwell upon the pathological changes which are obviously consequent upon diabetes, but only to deal with such as are presumably connected with its cause. Among the consequential changes is a form of "pulmonary consumption" which resembles that due to tubercle and is sometimes, but not always, tuberculous. The kidneys become inflamed, presumably as a result of the passage of the abnormal urine, and the same cause gives rise to irritation and inflammation of the external urinary organs. Cataract is engendered apparently by the physical action of the saccharine blood. But the morbid interest centres in the nervous system and the question whether the changes in the brain and cord are results of the disease or are antecedent to it. It is not impossible that the dilatation of the canal of the cord may be the result of an inflammatory process set up by the morbid blood. The same hypothesis may be hazarded with regard to the changes, be they of the nature of spinal myelitis or peripheral neuritis, which occasion the loss of the patellar reflex. I say these morbid conditions *may* be secondary to the glycosuria; it is not certain that they are so. But when we ascend to the brain we see probably not all there is to be seen, but certain things which are difficult to explain except as the results of morbid processes primary to the brain itself. Such are the evidences of morbid action in the perivascular canals, more especially the frequent hæmorrhages by transudation. Not that these are peculiar to diabetes; all that can be maintained is that they are not results of the saccharine state of blood, but are in some way connected with its cause. They indicate not so much irritating blood as an abnormal attitude of the blood-vessels, as if their walls had become relaxed owing possibly to some change in their innervation. Whence this change of innervation, if this there be, or how engendered, is as yet hidden from our view. There must necessarily be something behind, though we do not know what. If we could find some constant change in an appropriate vaso-motor centre we might discern in this the reason of the scattered arterial disturbances and the essential origin of the disease, but no such fundamental discovery has yet been made. Nevertheless what has been found means something; if we have not yet reached the root perhaps we have got hold of a branch. Disorders proper to the nervous system, chorea in particular, show a similar condition of the cerebro-spinal centres; this may be held to indicate that diabetes like chorea concerns these structures, though in neither case are we able to get deeper than what must be superficial manifestations.

Turning from the dead to the living I may recall the fact that the famous discovery of Claude Bernard that the urine of the rabbit was made saccharine by puncture of the floor of the fourth ventricle was anticipated in the human animal by the elder Larrey, the great surgeon of the First Napoleon. Bernard made the earliest experiments which led him to this conclusion in the year 1849. Baron Larrey[6] records a case which came under his observation in 1820 in which the same result was recognised from a similar cause. A fusilier, 22 years of age, received a thrust from a foil, from which the button had broken, through the inner wall of the right orbit, deep into the interior of the skull. Two and a half months after the accident he was suddenly attacked with diabetes, the urine displaying a large quantity of sugar. This condition lasted for seven days and then disappeared. Three months after the accident the patient died somewhat suddenly. After death it was found that the weapon had penetrated deeply into the brain, its course being indicated by a canal containing coagulum. This involved first the inner and fore part of the right hemisphere and then entered the left, piercing it as far as the lower wall of the left lateral ventricle almost to the medulla oblongata. This detached observation, made as it was 29 years before Bernard's discovery, has

a sort of prophetic interest and may be associated with much that has since come to light with regard to traumatic glycosuria. Many instances might be brought together in which injuries of the head have been followed by glycosuria, generally temporary. I have elsewhere[7] quoted the case of a railway guard who was knocked on the head by a lever in connexion with the brake and who subsequently passed saccharine urine in such abundance that all the vessels in a cottage to which he was taken did not suffice to contain it. I need not multiply cases of this sort, of which several will be found in my book to which I have referred. They are of the highest interest taken in connexion with Bernard's discovery and with the hypothetical origin of diabetes in the brain.

CLINICAL CAUSES OF DIABETES.

With these indications, as provided by morbid anatomy, physiological experiment, and human accident, we may glance at the ordinary clinical aspect of the disease in relation to the nervous system. Grief, anxiety, terror, may all be followed by diabetes so closely that there is no room for doubt as to their having occasioned it. The great Dr. Willis, the describer of the circle which bears his name, the first, so far as I know, to draw attention to the presence of sugar in diabetic urine, refers the condition to "the guzzling of strong drink" and to "sadness or long sorrow," and he held that "the nervous juices" had much to do with its origination. It is well known as a result of commercial disaster, and it may be said truly that every panic on the Stock Exchange produces its result in diabetes. It has recently come to light that engine-drivers are especially subject to this disease, presumably from the anxious nature of their occupation.[8] Dr. A. H. Smith of New York appears to have been the first to draw attention to this connexion which has been confirmed by Dr. Saundby on the authority of Mr. Herbert Page, surgeon to the London and North-Western Railway Company, who finds that the engine-drivers on this railway become diabetic in nearly twice the proportion of the ordinary population.

There are other causes of this disorder, the most prominent of which is heredity. Ancestral association does not bear upon this question of nervous origin; some nervous diseases are hereditary, so are others which have their origin elsewhere than in the nervous system. Diabetes presents itself together with gout with greater frequency than can be explained otherwise than by a pathological connexion between the two disorders. Gout causes, or at least precedes, diabetes as if diabetes were one of the consequences of the gouty state. The diabetes subsequently, when attended with much loss of sugar, is followed by a disappearance, or rather a non-recurrence, of the gout. Thus it would seem that gout causes diabetes and diabetes cures the gout. Of all the circumstances to which the disease can be attributed the two that stand out with the greatest prominence are heredity and mental impressions.

CLINICAL ASSOCIATIONS OF DIABETES WHICH RELATE TO THE NERVOUS SYSTEM.

The loss of the patella reflex has long attracted notice and may be regarded as one of the most constant signs of the disease. I have known this loss to be accidentally discovered when no other sign of diabetes had been recognised and sugar to be subsequently found. I should say that the loss of knee-jerk is an early manifestation of the disease and that it occurs in a larger proportion of cases than is commonly supposed. It is impossible not to connect this with some change either in the cord or in the nerves. I have not myself examined the peripheral nerves in diabetes, but others have without finding any morbid changes. As to the cord I need not repeat what I have already stated. Peripheral neuritis has been regarded as one of the results of the toxæmia of diabetes, and thus may arise the loss of reflex; on the other hand, it is not impossible that this loss may have to do with a primary change in the cord.

EARTHY PHOSPHATES IN DIABETES.

Another point of contact between diabetes and the nervous system is to be found in the occurrence of phosphaturia, an excess of the earthy phosphates, essentially phosphate of lime, in the urine in this disease. In certain conditions of nervous irritation the urinary phosphate of lime is increased sometimes to double its normal amount, or even more.[9] The action of liquor potassæ in its ready and conspicuous precipitation of the earthy phosphates affords a ready guide to states of the nervous system, of which worry and overwork are among the more prominent. Whether the phosphoric acid or the lime be the leading partner in the dance may be taken into question, since the superabundance presents itself in a combination of the two. Considering that brain-tissue contains much phosphorus and little lime, it is to be presumed that much wear or waste of brain may give rise to increased making and discharge of phosphoric acid and that the acid takes the earth out with it by virtue of their mutual affinity. However this may be it is a matter of familiar observation that in certain states of brain expressed by such terms as "worry" and "nervous irritation" the discharge of lime with the urine, virtually as phosphate, is increased. Many a student in expectation of an examination has been alarmed by the appearance of phosphate of lime in his urine, often in a crystalline form, though the shape is immaterial, to disappear when the peril is over-passed. But I need not repeat instances to show that phosphaturia goes with perturbation of brain.

Turning now to diabetes it appears that in severe and advanced conditions the increase of urinary lime (practically all in the form of phosphate) may be termed extraordinary, since it is unexampled in any other disease. I have placed on record a case where the daily excretion of lime exceeded three grammes, another where it exceeded two grammes, and several where it approached one gramme. The average of the urinary lime in health according to Dr. Parkes is 0·26. Call it 0·3 by way of being liberal. The maximum of my cases of diabetes was 3·38, 11 times the average of health. The calcareous increase in these cases does not wholly depend on the amount of urine, for it is out of proportion to the diuresis. To take a single example—a woman passed in one day 4980 cubic centimetres of urine, which was found to contain 3·38 of lime. Supposing that this urine contained only the normal percentage of lime this would amount for the whole quantity of urine to under one gramme. Thus the lime is increased out of proportion to the urine. Having regard to the affinity which exists between lime and sugar it may reasonably be suspected that the superabundance of lime in diabetic urine may depend on the attraction of the sugar for the lime, as a consequence of which the sugar carries out the lime with it. But the facts give no encouragement to this supposition. I found that a patient with severe diabetes under strict diabetic diet passed on an average of two days 3·28 grammes of lime. When the urinary sugar was largely increased by the addition of sugar to the diet the lime amounted to 2·76 grammes.[10] With more sugar there was less lime—as if the one did not directly depend on the other. Much has yet to be learned concerning the connexion of the nervous system with diabetes, but having regard to the undoubted relation of the excessive secretion of the earthy phosphates with certain conditions of cerebral irritation it cannot but be suggested as a provisional hypothesis that the extravagant exit of phosphate of lime in some cases of diabetes has to do with the state of the nervous system in this disease.

Another clinical fact in diabetes which suggests a connexion with the nervous system is the peculiar dusky redness of complexion which is often presented in severe and advanced cases. This is not a bright arterial flush nor is it venous lividity, but something between the two, not unlike what is sometimes connected with chronic alcoholism. Some degree of vaso-motor paralysis would explain the appearance. The peculiar tongue of advanced diabetes may be open to a similar explanation though another may be offered.[11] The dry tongue often becomes red and raw-looking and has been likened to raw beef. Hyperæmia of the mucous surface is obvious. This may be attributed to deficiency of saliva and consequent retention of irritant matters which are not washed off, or to a nervous failure which promotes the congestive process.

INSANITY AND GLYCOSURIA.

As possibly throwing light on the connexion of glycosuria with changes in the nervous centres it occurred to me many years ago to inquire whether this condition showed any bias in favour of lunatics. If both insanity and diabetes are results of changes in the brain it is probable, to say the

[10] Dickinson: Diabetes, p. 172.
[11] Dickinson: The Tongue as an Indication in Disease, p. 76.

least of it, that the lesions of insanity might sometimes be such as to make the urine saccharine.[12] I put this to the test at Bethlem Hospital with the result that among 106 lunatics the urine of 14 gave appreciable reductions of copper, together with some degree of darkening with liquor potassæ. I pass over minute evidences of reduction and such as were not confirmed by the potash test. Copper may be reduced by other things than sugar, and it may have been so in some of the cases in question, but in every one the reduction was decided. In three it was considerable and in all it was corroborated by liquor potassæ. I must add that in no instance did the urine or the symptoms present marked diabetic characters. The conclusion appeared to be indicated that glycosuria in small amount accompanied insanity, not frequently, but often enough to imply a morbid relation between the two. The proportion of glycosuria thus indicated, minute as might be the glycosuria and small the proportion, appeared to be necessarily abnormal, since sugar is no tangible ingredient of healthy urine. Dr. Hale White, who repeated my observations with the legitimate purpose of subjecting them to criticism confirmed them to a certain extent in so far that in the urine of 49 lunatics at Bethlem he found slight cupric reduction in five and undoubted sugar in two. As the testimony of an adversary (an adversary in a scientific sense only) this evidence is of value as presenting the irreducible minimum of concurrence. Here the question rested and remained in oblivion so far as I know for 19 years. My observations were published in the year 1877. In the years 1896 and 1897 Dr. Hubert Bond of the London County Asylum revived the subject with results which I will briefly recapitulate.[13] Putting together Dr. Bond's two papers the sum of his results is this. Among 355 recent cases of insanity Dr. Bond found sugar in the urine in 19, a proportion of 5·35 per cent. In addition to this series where the numerical proportion of saccharine to non-saccharine urine was ascertained Dr. Bond became acquainted with 13 other cases of insanity complicated with glycosuria, making a total of 32 instances in which the mental was associated with the urinary change. Dr. Bond appears to have made repeated examinations in every case and to have employed in each both the copper and the fermentation test. Taking all the evidence together the inference is not to be avoided that glycosuria in a small but tangible proportion of cases is a necessary concomitant of insanity. Insanity is a disease of the brain, though the morbid anatomy like that of diabetes can scarcely be said to have been reached by our crude and infantile attempts. Much remains for the future. But with both we have discovered indications of a pathology though not its essentials. It may be presumed that the cerebral changes which belong to insanity have something in common with those which give rise to glycosuria, though the relationship is evinced only in a minority of instances.

It must be confessed that we have not got to the bottom of the pathology of diabetes. Is it possible, then, that it has none, or rather none which is fundamental? Is it possible that diabetes is a "functional disease"? I say it is not possible. The phrase is useful as a cover for ignorance, but it is mischievous where it substitutes acquiescence for inquiry. If a machine goes wrong there must be something wrong in the works, or in the stuff supplied to it if the machine be of a consuming kind, or in the influences, motive power, and what not which are brought to bear upon it. If the machine goes wrong notwithstanding that it is supplied with proper stuff to work upon and actuated with proper moving powers there must be something wrong in the machinery which we ought to be able to find out. If a mill were to go wrong and to discharge bran where it ought to discharge flour we should scarcely be satisfied with the engineer who assured us that the mischief was functional. If the perverted action which constitutes diabetes persists notwithstanding that the material supplied to the organism and the circumstances by which it is surrounded are such as in other cases are attended with no such perversion we must look into the organism for the cause of the error, for though we may not succeed in finding it it is surely there.

What may be called the superficial morbid anatomy of diabetes has been sufficiently dwelt upon with due allowance for what may be consequent upon the disease rather than antecedent to it. Enough remains to give significance to certain clinical observations: the undoubted origin of the disease in mental causes; its association with a larger excretion of phosphate of lime than can be accounted for by the diuresis and which presumably has to do with the nervous phase of the disease; the loss of the patella reflex, which must be taken *cum grano* as of somewhat uncertain bearing; and, finally, the concurrence of glycosuria with insanity, which is too frequent to be accidental.

ABSTRACT OF

A Clinical Lecture

ON

FEMORAL HERNIA.

Delivered at St. Thomas's Hospital on Oct. 19th, 1900,

BY WILLIAM H. BATTLE, F.R.C.S. ENG.,

ASSISTANT SURGEON AND JOINT LECTURER IN PRACTICAL SURGERY, ST. THOMAS'S HOSPITAL.

GENTLEMEN,—Although in the majority of instances it is possible, especially in hospital practice, to distinguish a femoral from other forms of hernia met with in the groin, there are cases in which it may be not only difficult but almost impossible without operation. Few surgeons of much operative experience are unable to recall examples of such mistakes. It is very easy for you to remember the anatomical landmarks which define the position of a femoral hernia, how its neck is situated below Poupart's ligament, to the outer side of the pubic spine and to the inner side of the femoral vessels. As a guide in ordinary practice, if you wish to find the ring quickly place the tip of the finger on the femoral artery immediately below Poupart's ligament, allow half an inch to the inner side for the femoral vein and then comes the femoral ring. You must make yourselves acquainted with the various points mentioned by examining carefully the patients who come before you in the out-patient department. In the ordinary subject of this hernia [a specimen of which was shown] you may have no difficulty in finding the pubic spine, but when the patient is a woman and stout and makes examination difficult it may be hard to define the adductor tendon which acts as a guide to that point of bone. Most of the mistakes in diagnosis arise in stout women who refuse a proper examination, and there are many such. Even when suffering from strangulation of the bowel in a hernia they may deny the presence of a swelling in the groin and refuse to be examined, although they are told that their life may depend upon it. I have recently heard of a case in point, that of a woman who refused examination for three days and in whom the gut was gangrenous at the operation, which, of course, was performed as soon as the hernia was found. It would be your duty in such circumstances to insist on the examination or to retire from the case, giving your reasons for refusing to take the responsibility of it. In the very stout it may be difficult to find a small hernia, although strangulated, the pain being chiefly referred to the umbilicus and not to the femoral region, whilst examination elicits no complaint of tenderness from the patient. I have twice been called upon to operate for intestinal obstruction when in each case the cause was femoral hernia of small size which had been overlooked. Examine the groins carefully in all cases of intestinal obstruction.

As the sac of a femoral hernia often turns up over Poupart's ligament the hernia may be mistaken for an oblique inguinal, but it is usually possible to feel the neck of the sac extending downwards to the femoral ring, and the direction in which the contents can be reduced indicates the line of the sac. If the patient is intelligent the history of the point of commencement and duration of enlargement of the rupture will probably assist you. Interstitial hernia may (but rarely) simulate a large femoral hernia as shown by an illustration in Macready's treatise on ruptures. Abdominal hernia, the variety which comes through the lower part of the linea semilunaris, may resemble an exceptionally large protrusion through the femoral ring. As regards strangulated femoral hernia I do not intend to say more at present than advise you to insist on early examination of the femoral region. When a

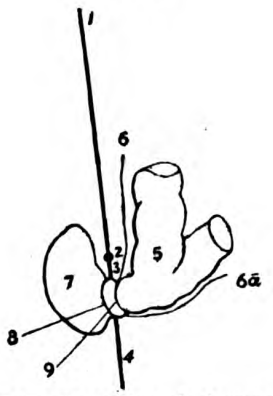
patient has symptoms of intestinal obstruction do not take it for granted that he will know if there is a hernia, for patients are often ignorant of the fact. Remember also in the operation when dividing the edge of Gimbernat's ligament to cut as little as possible, using a blunt knife. Do not make the tendency to hernia worse by enlarging the opening unnecessarily.

We have to consider the diagnosis of this form of hernia from other swellings in the femoral region, and in the first place it is well to ascertain if there is a hernia or not. I have recently had under my care a patient sent to me by Dr. Donelan in whom the sac is so thin that it can hardly be felt when she is lying down, but when she stands and coughs there is no doubt of the presence of a femoral hernia. Some of us could not find it when she was examined lying down. Examine your patient when standing, afterwards when lying down on the back. In most cases it is easy to state whether a hernia is reducible or not; there is a definite swelling which goes back on lying down and it is easy to feel the empty sac where you expect to find it. In some this sac feels lobulated and thickened and there may be difficulty in arriving at the correct opinion as to the presence of a thickened fatty sac or an irreducible omental hernia—the sensation conveyed to the hand may be much the same. If there are no symptoms pointing to the involvement of abdominal contents in the hernia the history of the case may afford a clue; for instance, the patient may state that the hernia had suddenly become larger and remained so; a date on which this occurred may even be mentioned. A sign which may be elicited in cases of irreducible femoral hernia is the dragging on the sac of which the patient complains when pressure is made over the lower abdomen on the affected side, especially if the abdominal walls are lax. I think this sign of more frequent usefulness than that of feeling the band of omentum or mesentery which may be adherent. In the reducible form a condition which is frequently mistaken for a hernia is a varix of the internal saphena vein. Some of you will remember a case sent in for radical cure during the summer, and may remember the difference between the two—the swelling was lower down, the impulse on coughing was accompanied by a thrill, and after lying down when a finger was placed over the femoral ring the resumption of the erect position with the finger still applied did not prevent a return of the swelling; its colour was bluish; there were no other dilated veins in the limb, but such are usually found. Excision of a portion of the vein below it sufficed to cure it. The ordinary psoas abscess does not much resemble a hernia unless the fascia below Poupart's ligament has yielded and permitted the abscess to bulge forwards; in this case it may have a soft elastic feel, very like a hernia of intestine; but it is dull on percussion, is but partly reducible, and fluctuates above and below the ligament. Evidence of spinal disease will usually be found—if looked for.

When the hernia is irreducible there are two conditions which may be mistaken for it—enlarged glands and lipoma. Here, again, the evidence of a pedicle must be sought for passing into the femoral ring. Careful inquiry into history (as mentioned in the reducible form where a fatty sac remains) must be made. There is not much difficulty in most cases of glandular enlargement, for there are usually several glands affected, but if the gland is single and placed over the saphenous opening with an attachment to deeper parts the diagnosis is less easily made, and in the absence of a cause for the enlargement and a doubtful history it may be advisable to explore. A year ago a young man was admitted with a swelling in the left groin over the saphenous opening. He gave a history of sudden onset five days before with vomiting and constipation. The testis was absent from the scrotum on the same side and he had some fever. Exploratory incision showed a gland-like body over the femoral ring with a pedicle passing into the canal; in this was a fair-sized artery. This was removed and he rapidly recovered. The glandular swelling was an enlarged lymphatic gland.

Irreducible inflamed hernia and enlarged glands may be co-existent, the glands being enlarged in consequence of absorption of inflammatory products from the sac contents. In a case of this kind sent to my care by Mr. A. J. Southey of Colnbrook I was able to come to a right conclusion as to the presence of a hernia by the history of the case, and at the operation found an inflamed and adherent appendix vermiformis in the sac, closely surrounding and attached to which were several inflamed glands. Hydrocele of the hernial sac occurs with sufficient frequency to require consideration; in this there is an accumulation of fluid in a sac which is shut off from the general peritoneal cavity. This occlusion may arise from adhesion of the omentum or of the intestine to the sac, or as a result of adhesion of the opposed peritoneal surfaces possibly caused by this pressure. The accompanying diagram (Fig. 1) was used to illustrate the changes

FIG. 1.



Vertical antero-posterior section. 1, Aponeurosis of the external oblique. 2, Poupart's ligament. 3, Falciform process. 4, Fascia lata of thigh. 5, Intestine with lateral projection into the canal. 6, 6a, Peritoneum. 7, Larger sac. 8, Firm fibrous membrane separated from the adherent intestine by the fluid contained in the smaller sac, 9.

found in a case under my care some years ago,[1] at a time when hydrocele of the hernial sac was not so well known as at present. When comparatively small there is not much difficulty in the diagnosis, but when larger—and they may attain large size—psoas abscess, hydatid, and distension of the bursa under the psoas muscle must be considered. A small chronic glandular abscess may resemble a small hydrocele, but careful consideration should prevent a mistake.

An interesting case of hydrocele of the sac was recently sent to me by Dr. Wansbrough Jones of Harrow. The patient, a girl, aged 22 years, had a swelling over the external abdominal ring, which it occupied completely, there was an impulse on coughing, but not reduction on pressure. It was internal to the spine of the pubes. When submitted to operation we found a hernial sac containing free fluid and from this sac a narrow neck was found to pass, not along the inguinal canal but downwards over Poupart's ligament to the femoral ring. The fluid had accumulated in consequence of the sharp bend in the narrow neck of the sac in the unusual course taken by it. Cases of femoral hernia which have been submitted to operation may present curious developments in the sac, but it is rare for them to simulate inguinal hernia, though such are recorded.

When a femoral hernia is irreducible it should be submitted to operation unless there is something in the state of the patient to contra-indicate it. You must then arrange for the proper adjustment of a truss according to the necessity of the case, but my experience of such treatment is that it is not often successful in preventing strangulation in later life.

To consider the radical cure of femoral hernia is to approach a subject of much interest, and many procedures have been recommended at various times and by different surgeons to solve this problem. The chief of these are: 1. Simple ligature of the sac. This method, like that employed formerly in the attempted cure of inguinal hernia, does not diminish the size of the opening through which the protrusion has passed, nor alter to any extent the conditions which predisposed to the hernia. By itself it can seldom succeed, but it is a preliminary part of the operation in the following methods unless the contrary is expressly stated. 2. Isolation of the sac and its displacement upwards into the abdominal wall (Kocher's method). 3. Closure of the saphenous opening by suture of the pubic to the iliac portions of the fascia lata. 4. Suture of Poupart's ligament and

[1] THE LANCET, Feb. 26th, 1887, p. 413.

falciform process to the fascia over the pectineus. 5. Suture of Poupart's ligament to the periosteum of the pubic ramus. 6. Formation of a flap from the fascia over the pectineus and its implantation into the femoral ring. 7. Formation of a flap from the pectineus muscle and its implantation into the femoral ring. 8. Excision of the sac, suture of the peritoneal opening, clearing of the femoral canal. The anterior wall of the canal (with Gimbernat's ligament) is then sutured to the posterior wall, Poupart's ligament is sutured to the fascia over the pectineus, and finally sutures are placed to close the saphenous opening (Stimson).

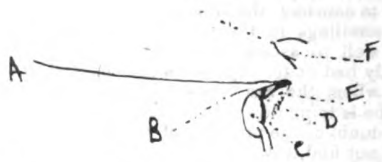
The question which of these methods (if any) will give the desired result is not one that can be decided at once without a consideration of many factors in the case. The most important of these are the age of the patient, the size of the femoral canal, and the general condition. You will do wisely not to pin your faith on any one method as suitable to all cases. It is of importance to consider the age of the patient, because the suturing of tendinous structures to fascia cannot be expected to succeed in a patient who has a fatty degeneration of that tissue, and this is often found in the subjects of femoral hernia who are getting on in life. Again, if the femoral canal is large and rigid as the result of distension by a long-standing hernia, sutures are very likely to yield to the strain and to cut out of the fascia into which they have been passed. The general condition of the patient as at the termination of an operation for strangulation is also important, as the shortest method of treatment likely to assist in making things secure, if only for a few months, may have to be adopted.

In many instances when the ring is small simple suture of Poupart's ligament to the fascia over the pectineus will suffice if the sac has been ligatured and the stump pushed well into the upper part of the canal. I have used the flap of muscular tissue raised from the pectineus and impacted in the canal, but the result was unfortunate. The muscular flap atrophied and the patient appeared later with a hernia much increased in size and a femoral ring which was decidedly larger than before the operation. I have also tried a flap of fascia raised from the pectineus, but do not think that more good resulted than from suture alone. Mr. Carwardine speaks highly of Stimson's method, but there are two things which would make me hesitate to employ this—one is the number of sutures required in such a small area and inserted in structures of low vitality; the other is that the femoral canal is not to my mind satisfactorily blocked at its upper end.

In thinking over the question of radical cure it seemed to me that we required a method which would enable us not only to bring the remains of the sac into the abdomen, but also to place an obstacle to the descent of a hernia between this and the canal. A plan for making a shutter out of the external oblique described below occurred to me and I have successfully performed the operation in three cases, one male and two female. The inguinal canal is strengthened by the operation, its outer wall being doubled and the external ring diminished in size. Not many months have elapsed since the first case was operated on, so it is not possible to speak about the ultimate result, but I am hopeful that it will prove effective (it has answered well so far) and stand the test of time.

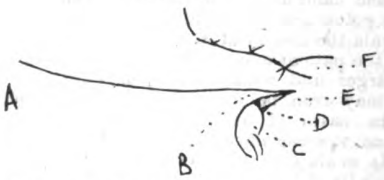
The last case and the operation performed are as follows. A married woman, aged 23 years, was admitted to St. Thomas's Hospital under my care on July 4th, 1900, for an irreducible femoral hernia on the right side. She could not say how long there had been a swelling in the groin, but it had been there for at least two years, and she did not think that there had been any increase in size during the past four months. The hernia could only be partly reduced when the patient was lying on her back. Some omentum remained, the intestine going back easily, and the hernia quickly recurred when she stood up. The opening through which the protrusion came admitted a large forefinger. The general condition was satisfactory. She had never undergone operation or worn a truss. On July 12th the following operation was performed. A vertical incision was made over the sac and portion of abdominal wall adjoining it, directly over the line of the femoral canal. The sac was exposed, opened, and the contents were reduced after ligature and division of adherent omentum. The sac was then dissected out, ligatured at its neck with silk, and cut away. This silk ligature was kept long. The first incision which exposed the sac also exposed the aponeurosis of the external oblique and by the use of a retractor in the upper part of the wound the external inguinal ring was easily defined to the inner side. Incision was made outwards from this and the aponeurosis of the external oblique was divided in a line almost parallel to

FIG. 2.



Poupart's ligament and along the course of its fibres. The external pillar of the ring and aponeurosis of external oblique muscle attached to it were now separated from the contents of the inguinal canal down to the femoral canal. The neck of the sac, freed from its attachments, was lifted out of the

FIG. 3.



latter by its ligature, which was then cut short. Sutures of thin silk were inserted in the upper part of the severed aponeurosis, which easily came down, and carried as indicated in the diagram (Fig. 3). No 1 was secured to Poupart's ligament over the femoral vein; No. 2 passed through the femoral ring and then into the fascia over the pectineus, which formed the posterior boundary of the ring; and No. 3 was sutured to Gimbernat's ligament. By this means a shutter of great strength was secured at the upper end of the femoral canal. Additional sutures were then

FIG. 4.

placed as follows: three to unite the lower half of the external wall of the inguinal canal to the aponeurosis, which was now beneath it, and two to close the femoral ring further by drawing the pectineal fascia and

Poupart's ligament into apposition. The aponeurosis was thus fixed not only by the deep stitches but also by the more superficial ones and could not slip back to its former position. Any dragging on the aponeurosis would thus be at the junction of the two parts of the inguinal canal and not at the line of insertion of sutures. The external wall of the inguinal canal was thus doubled in thickness throughout most of its width and the external ring was diminished in size. The wound was closed in the usual way and healed by first intention. The only thing noticeable now besides the scar is some want of fulness of Scarpa's triangle owing to absorption of fat from pressure of the former hernia. The operation requires strict antiseptic precautions and it is desirable to clear the outer surface of the lower part of the inguinal canal from the overlying fascia. I think this method of operation suitable to cases in which the canal appears too large for the ligature of the neck of the sack and the suturing of Poupart's ligament to the fascia over the pectineus to be done with a prospect of success. There are some cases which may be beyond relief by this method, of which the following is an example.

The patient was a woman aged 56 years. She had suffered from a hernia for 30 years, and it had been irreducible for 27 years. About five years ago she had symptoms of strangulation, which were relieved by operation at another hospital, but as no account of the operation was kept I am unable to say what was done, but probably no radical cure was attempted. She came into St. Thomas's Hospital on Dec. 8th, 1899, with a complaint of pain in the rupture and of vomiting. The hernial swelling was very large, thin-walled, shaped like a big sausage, and when she stood, reached almost to her knee. There was a scar over it remaining from the former operation and the hernia could not be reduced. The contents appeared to be almost entirely intestinal in character. The opening through which they had come was large and it was difficult to imagine how a femoral ring could be dilated sufficiently to permit of the passage of such a large protrusion. Her condition was unsatisfactory, she was feeble and suffered from chronic bronchitis, and was not then in a good condition for operation. Had the symptoms continued, however, it would have been necessary to operate at once, but rest and proper diet relieved her and whilst attempts by means of elastic pressure to reduce the hernia were being made, her bronchitis was satisfactorily treated and her general health improved considerably. On Jan. 8th, 1900, the hernia was subjected to operation and the opening through which it had come was closed. A long incision was made over the upper part of it extending over the lower abdomen, the thin sac was opened, and the contents (all small intestine) were reduced; this was not quickly or easily effected as the intestinal coils were thickened, adherent to each other and to the lining of the sac. The opening into the peritoneal cavity easily admitted four fingers and all around the peritoneum was closely adherent to the fibrous structures, so that the neck of the sac could not be tied; it was sutured like the peritoneum of an abdominal wound after the sac had been separated and excised. Sutures, also of silk, were then inserted between the deep fascia of the thigh and Poupart's ligament, both internal and external to the femoral vessels. The pectineal fascia was very fatty. A large piece of redundant skin was then removed and the superficial wound was stitched with silkworm gut. A drainage-tube was inserted. Some localised suppuration followed in the upper part of the wound, but it was not extensive, and there was some return of the cough, but she was able to leave the hospital and has been seen since. The wound has soundly healed and is without bulging. This hernia is the largest femoral hernia that I have seen, and had the abdominal walls been at all rigid there might have been some trouble in reducing its contents into the abdomen. There was formerly a cast[2] in our museum at St. Thomas's Hospital which showed a femoral hernia of even larger size. It extended to within an inch of the knee-joint and in its lower part was an artificial anus through which the fæces were discharged. The coverings were so thin that the peristaltic movements of the intestines could be seen through them.

BRISTOL NATURALISTS' SOCIETY.—Dr. A. B. Prowse has been elected President of this society for the ensuing year.

THE HÆMORRHAGIC DIATHESIS IN TYPHOID FEVER AND ITS RELATIONSHIP TO PURPURIC CONDITIONS IN GENERAL.[1]

BY ALBERT G. NICHOLLS, M.A., M.D.,
LECTURER IN PATHOLOGY, MCGILL UNIVERSITY, AND ASSISTANT PATHOLOGIST TO THE ROYAL VICTORIA HOSPITAL, MONTREAL;
ASSISTED BY
G. EVERETT LEARMONTH, B.A.,
STUDENT IN MEDICINE, MCGILL UNIVERSITY, MONTREAL.

IT is a matter of common observation that in certain infectious and presumably infectious diseases like typhus fever, scurvy, Werlhoff's disease, and peliosis rheumatica, hæmorrhagic eruptions develop in the skin and mucous membranes. That which is the primary and cardinal train of symptoms in these diseases may be found exceptionally as a complication in certain others, like variola, scarlet fever, measles, enteric fever, cholera, yellow fever, sepsis, and acute atrophy of the liver.

In the course of typhoid fever or enteric fever a number of examples have been recorded during the past two decades where hæmorrhagic complications have supervened. Of course, minor hæmorrhagic manifestations, like epistaxis which so frequently ushers in the attack, or like intestinal hæmorrhage which is present in a considerable proportion of ordinary cases, are common enough, while either of these conditions may, under certain conditions, be part and parcel of a general hæmorrhagic tendency and represent its first symptom. This does not in itself constitute the hæmorrhagic diathesis. This term should be restricted to those cases where multiple hæmorrhages take place and which are evidenced clinically by purpuric eruptions into the skin, oozing of blood from the mucous membranes, epistaxis, hæmoptysis, hæmatemesis, melæna, or metrorrhagia. All of these symptoms, of course, may not be present simultaneously, since very varying grades of the condition exist. Most authorities are agreed that such occurrences are very rare, though their possibility has been recognised for many years.

Some hesitation has arisen in our minds in regard to the proper expression which should be used to designate this interesting form of typhoid fever. The term "hæmorrhagic diathesis" is possibly open to criticism, since to many minds it connotes the idea of some pre-existing constitutional deficiency or dyscrasia of the blood or some congenital weakness of the blood-vessels. With the single exception of certain of Wagner's cases, to be referred to later, such inherited defects can usually be excluded in the type of disease under consideration, and yet it is clear that there is at work some serious disturbance of the blood. Further, the term "purpura hæmorrhagica" is not altogether suitable, since it has not been settled between clinicians and pathologists what conditions are properly to be included under this designation. Litten, for instance, restricts the term to Werlhoff's disease, Schönlein's disease, and some others, and would deny it to the purpuras which occur in variola, typhoid fever, sepsis, and mineral poisoning. We must, however, dissent strongly from Litten's view, for the trend of recent pathological research, as we shall see, is to prove that the prime factor underlying the vast majority of cases is some systemic intoxication, either bacterial, chemical, or animal, and there is no sufficient reason for believing that Werlhoff's disease and the group of so-called "idiopathic purpuras" differ essentially from the others in this respect.

That circulating toxins, bacterial or otherwise, do produce marked alterations in the quality and composition of the blood and lead to degenerations of the blood-vessels may be regarded as proven. Since, then, we have to admit a serious qualitative vitium in the blood, even though it be acquired, and since we are unable entirely to exclude the presence of some inherited defect, it would seem fairly scientific and at the same time less liable to misapprehension if we use the designation "hæmorrhagic diathesis" for these cases in preference to any other.

[1] We desire to express our thanks to Dr. W. F. Hamilton of the Royal Victoria Hospital, Montreal, for the opportunity of recording this case of hæmorrhagic typhoid fever.

We in Montreal have had the unusual experience of meeting with four cases of a more or less hæmorrhagic type in a series of about 200 cases of enteric fever from the clinic of Professor James Stewart at the Royal Victoria Hospital. These were recorded by one of us (Nicholls[2]) in 1896, but at that time little attempt was made to analyse the clinical symptoms or to determine pathological conditions.

In the present communication we are enabled to report an additional most extreme example of enteric fever with the hæmorrhagic diathesis, which has been very carefully worked out and which will, we hope, help to place the subject on a more satisfactory basis.

The hæmorrhagic type of enteric fever has for years been recognised as a clinical entity and was first brought into notice by the earlier French school, notably Trousseau, who referred to it under the name of "*fièvre putride hémorragique*." Liebermeister in Von Ziemssen's Cyclopædia notes the occurrence of hæmorrhages from the nose, gums, stomach, bowels, lungs, kidneys, ecchymoses into the skin, and extravasation of blood into the various organs and serous cavities. He further remarks that hæmorrhages into the skin, true petechial vibices, are most likely to occur in patients of a hæmorrhagic diathesis, but occasionally appear in others. Murchison[3] had occasionally observed hæmorrhages into the muscles. Wilson and Loomis mention hæmorrhages from mucous surfaces and in the skin. Wood and Fitz[4] state that "hæmorrhagic typhoid fever is a very deadly complication of the disease, especially prone to occur in debilitated subjects suffering from scorbutus, alcoholism, &c. There is in it a rapid alteration of the blood with profuse hæmorrhage from the nose, mouth, intestines, and kidneys—indeed, from all the mucous membranes, the formation of abundant ecchymoses, blotches, and suggillations, &c. In these cases the adynamia is extreme from the beginning, the fever is high, the pulse very rapid and small, heart's action greatly enfeebled, tongue and mouth loaded with a brownish deposit, the breath very fœtid and even ammoniacal. Death usually occurs before the tenth day in these cases and has been recorded as early as the third."

Osler[5] says of hæmorrhagic typhoid fever: "This is excessively rare. ..... Hæmorrhages may be marked from the outset, but more commonly they develop during the course of the disease. The condition is not necessarily fatal." Hare[6] in his admirable monograph on "The Medical Complications of Typhoid Fever" states that "hæmorrhagic eruptions may occur in the course of typhoid fever, and, as a rule, they appear in the neighbourhood of the joints, when the exudation may be small or quite large."

It is somewhat singular that the cases of hæmorrhagic enteric fever published during the past four or five years have been regarded chiefly as clinical curiosities and no attempt has been made to study the condition fully or to ascertain its cause. Indeed, in most even the clinical features are very inadequately described, and in a very few where a post-mortem examination has been made the investigation has been, to say the least, very superficial. After a careful study of the recorded cases we have been obliged to conclude that they are of little scientific value and do not materially advance our knowledge of the intimate nature of this process. In the case herewith presented we have endeavoured to make a minute examination of the various organs in the hope of arriving at a more adequate conception of the processes involved. The case was as follows.

A female, unmarried, aged 21 years, a school-teacher, was admitted to the Royal Victoria Hospital under the care of Dr. W. F. Hamilton on June 19th, 1900, with headache, anorexia, and pain in the back. Her history was as follows. She was born in Canada. She had had measles eight or nine years previously, but no other illness; her habits were regular and her food and clothing were satisfactory. Her father was subject to asthma; her mother was weakly and "bothered with her kidneys"; and two sisters were dead (one from diphtheria). Careful questioning failed to elicit any evidence of hæmophilia or rheumatism. The patient first felt ill six days before admission, but kept at work for two days. The illness began with chill, pains in the back, and following this some fever. The condition persisted and gradually got worse until she applied for admission to the hospital. On admission the patient was a well-nourished girl of medium size. Her face was flushed, her eyes were dull, and her lips were dry and sore. The temperature was 100° F., the pulse was 98, and the respirations were 22; the mucous membranes were pale. The pulse was regular and of good volume; tension was slightly *plus*. The apex beat was visible in the fifth intercostal space, two and three-quarter inches from the mid-sternal line. Cardiac dulness was normal. On auscultation the first sound at the apex was rather muffled; at the base the pulmonary second sound was extremely accentuated. With regard to the respiratory system expansion was good; a few fine crackling râles could be heard over the base of the right lung posteriorly; the lungs otherwise were normal. The tongue was dry and caked; it was moist at the edges. The teeth were covered with sordes; anorexia was marked; the bowels were regular. The abdomen was slightly prominent below the level of the umbilicus. There was no rigidity; general tenderness was present. The percussion note was tympanitic throughout. The spleen was doubtfully palpable. The liver was not palpable and dulness was normal in extent. The skin was hot and dry. Numerous rose-spots were present upon the abdomen. The muscles were small and flabby. The lymphatic glands were not palpable. The intelligence and memory were good; there was no headache; the patellar reflexes were increased. Menstruation began at 14 years of age and was normal. On June 7th, 14 days from the onset of the first symptoms, a hæmorrhagic area made its appearance near the umbilicus following the application of an ice-bag. There was distinct ecchymosis of the skin of a dark purple colour which did not disappear on pressure. On the 20th the abdomen was still distended but less tender. On the 29th the patch on the abdomen was fading. During the night the patient had two intestinal hæmorrhages and multiple hæmorrhages were present over the left half of the trunk posteriorly. On the 30th, during the night, there were profuse epistaxis and hæmorrhage from the lips and gums and effusion of blood into the conjunctivæ, and during the day there was hæmaturia. A blood count gave 13,000 leucocytes. Widal's reaction was present. On July 1st subconjunctival hæmorrhages of the right eye had partially disappeared, but now there was hæmorrhage below the right lower eyelid. The urine still contained blood, but there was no vaginal bleeding. There were a few subcutaneous hæmorrhages upon the trunk. During the night there were epistaxis and hæmorrhages from the back of the throat. On the 2nd ten ounces of saline solution were injected below the mammæ. A few subcutaneous hæmorrhages appeared upon the lower limbs. The patient was much weaker. A blood count gave 1,540,000 erythrocytes and hæmoglobin 35 per cent. On the 3rd the patient did not sleep and became gradually weaker and died at 8.40 A.M. The treatment adopted was as follows. Cold baths, 18 in all, were given until the hæmorrhagic tendency developed. Spirit of turpentine and liquor calcis chloridi were given internally; applications of suprarenal powder in glycerine were made to bleeding mucous surfaces.

This case may be described as one of typhoid fever of moderate severity occurring in a young person in previously good condition. The course was typical except that the disease set in with a chill and the spleen was at no time definitely discoverable by palpation. The abdomen was not particularly distended and the bowels were regular, moving generally once daily; during the last three days of life the bowels were constipated. The highest point which the temperature reached was 104·3° on the day of admission. During the following four days the temperature kept about 103° or 102·2°, being reduced about two degrees by the tubs. During the next three days the temperature averaged about 101·2°. On June 29th, when the hæmorrhages from the bowels took place, the temperature in the course of seven hours dropped from 103° to 100·2°, but rapidly returned to 102·3°. On the 30th the incidence of the submucous hæmorrhages led to a more decided fall, the temperature coming down to 98·2°; the return was almost immediate to 101·3°. On July 1st the average was 100°, on the 2nd 99·2°, and at death on the 3rd the thermometer fell to 95·2°. The character of the temperature curve at no time suggested the idea of any septic infection, nor was it affected by the development of the hæmorrhagic diathesis in any other way than is usually seen in enteric fever where there is considerable loss of blood.

Necropsy.—A post-mortem examination was made two

hours after death by Dr. W. W. Ford. The body was found to be that of a well-developed young female presenting the usual signs of death. The skin and mucous surfaces were pale. The breasts were well developed, the genitalia were normal, and the rectum was normal. In the left eye hæmorrhage had taken place into the sclerotic at the internal canthus. There was also slight hæmorrhage into the conjunctiva of the right eye in the neighbourhood of the inner canthus. The skin below both lower eyelids was discoloured. The mucous membrane of the lips showed small ecchymoses; the pharynx was apparently normal. There was subcutaneous discolouration below the right breast at the site of the saline injection. There were a few dark areas of subcutaneous hæmorrhage over the left buttock. Petechial spots were scattered rather plentifully on the skin of the trunk in front together with some irregular ecchymoses; one most striking feature was a large ecchymosis, roughly oblong in shape, about 12 centimetres across, which was situated near the umbilicus and represented the site where the ice-bag had been applied. A few petechial spots and small ecchymoses were present on the left thigh just above the knee and above the left internal malleolus. The cranium was not touched. The diaphragm reached to the height of the fifth rib in the right side and the fourth on the left. The right lung presented a few old adhesions posteriorly and to the diaphragm. The pleural surface of both lungs showed numerous punctate hæmorrhages. The right lung weighed 460 grammes. The bronchi were filled with frothy fluid; the mucous membrane was normal. The tissue on section was congested and œdematous and numerous indefinite patches of hæmorrhage, some of them of the size of small peas, were present throughout the substance. The edges of the lung were emphysematous. The left lung weighed 450 grammes. On section it was found to be congested about the posterior surface; in other respects it was similar to the right. The heart weighed 190 grammes. The right ventricle was filled with red blood-clot; all the valves were normal. The tricuspid orifice admitted the tips of two fingers. The edges of the mitral valves were a trifle thickened; the mitral orifice admitted three fingers. The left ventricle was filled with blood-clot. The heart muscle was pale and contained a few pin-point hæmorrhages. In the abdomen there was a fair amount of subcutaneous fat of a normal deep straw colour except at the umbilicus, where it was discoloured by free extravasation of blood into the tissues. On opening the abdomen the intestines were found to be slightly distended. The great omentum lay coiled up on the left side below the spleen. The peritoneum was smooth and glistening. The appendix lay on the brim of the pelvis pointing upward and inward; no fluid was found in the peritoneal cavity. The retro-peritoneal tissues over almost the whole of the lower part of the abdominal cavity were occupied by a large recent hæmorrhage which spread over the whole surface of the pelvis, over the top of the bladder to the front, and towards both sides. The spleen weighed 90 grammes; the surface was smooth and the capsule was rather wrinkled and showed a few minute subcapsular hæmorrhages. On section it was rather friable but was not congested or juicy. Except for the points noted it was practically normal and was far removed from the appearance of the ordinary typhoid spleen. There was nothing special in the stomach. In the duodenum, one inch below the pylorus, there was a minute pale scar as if from a healed peptic ulcer. The peritoneal surface of the small intestines showed numerous areas of a dark red colour. The serous coat, however, was smooth and showed no signs of exudate. At these points the intestinal walls were thickened and the patches evidently corresponded to hæmorrhages into the inflamed patches in the bowel wall. The mesentery was occupied by a large hæmorrhage which was dark red in colour. On cutting into this the blood was found to be coagulated. The lymphatic glands of the mesentery were enlarged and succulent. In the ileum the Peyer's patches were only slightly swollen, showing marked hyperplasia of the lymphoid elements. One of these patches showed hæmorrhage into its substance. In the lower part a few shallow serpiginous ulcers were present. The peritoneal surface of the rectum and the meso-rectum were occupied by a number of hæmorrhages. Numerous hæmorrhages were also present in the appendices epiploicæ of the sigmoid flexure and the rectum, dark red in colour. The mucous membrane of the large intestine was congested and catarrhal throughout. The solitary follicles were numerous and somewhat swollen. Many shallow and some deep ulcers were present in the cæcum about the ileo-cæcal valve and in the first part of the colon. The bases were somewhat indurated. The ulcerations were fairly characteristic of typhoid fever at the end of the third week, except that they appeared to be more indurated than usual. This was explained by the fact that many of these were infiltrated with dark-red blood which caused the bases and edges to appear to be thickened, somewhat masking the typical appearances. The ulcers in the neighbourhood of the ileo-cæcal valve were large and sinuous. About 30 ulcers all told were present in the intestines. The mucous membrane of the rectum was apparently normal; the rectum was filled with clotted, dark greenish, altered blood. The pancreas weighed 130 grammes. On section it was found to be of pale colour and well lobulated. A few minute hæmorrhages were present upon the surface. The lymphatic glands in the neighbourhood were large and succulent. The liver weighed 1225 grammes. Its serous surface was smooth; on section it was markedly pale with cloudy swelling. No fæcal necroses were seen. No hæmorrhages were present. The gall-bladder was filled with dark-coloured bile. The wall, where the organ was attached to the liver, was infiltrated with blood. The left kidney weighed 140 grammes. Its capsule peeled off with ease. Many small pin-point hæmorrhages of a dark reddish-brown colour were noticed on the cortex. The surface was congested. On section the organ was very much congested, the glomeruli showing as reddish points. Numerous hæmorrhages were seen in the Bowman's capsules and along the course of the interlobular and straight vessels. The cortex measured 18 millimetres in thickness. The kidney was fairly firm and was of a dark greyish-brown colour. The right kidney weighed 120 grammes; in all respects it was similar to the left. The mucous membrane of the bladder was pale and showed above a few submucous hæmorrhages. The bladder was filled with clotted blood and there was a very large submucous extravasation of blood in the lower two-thirds of the organ posteriorly, from which the oozing apparently had taken place. The uterus was small; the external os contained blood-stained mucus. The vagina contained no blood. The ovaries were small; the left contained a few clear cysts of small size; there were no hæmorrhages. The Fallopian tubes were normal.

Microscopical examination. — Stained with Ehrlich's hæmatoxylin the fibres of the heart muscle were somewhat thin and wavy. The staining of the nuclei was faint and the transverse striation was indistinct. The longitudinal fibrillation was well marked. Beyond some cloudiness there was no special change. In sections stained by the carbol-thionin and Gram-Weigert methods no bacteria were seen. Hæmatoxylin preparations of the lung showed small irregular hæmorrhagic patches here and there throughout the tissue. These were somewhat poorly defined at the margins, passing off gradually into the more healthy condition. The alveolar walls throughout were on the whole rather thin and those within the infarcted areas were much compressed. The walls everywhere stained fairly well. The interstitial tissue showed slight anthracosis. Small areas of collapse were noted in many portions. There was distinct catarrh of the lining endothelium of the alveolar processes, many of the alveoli being filled with, in addition to a few red cells, large mononuclear cells containing granules of pigment and débris. The débris in part consisted of broken-down erythrocytes. No emboli were seen.

Portions of the tissue were stained with osmic acid (Fleming's solution) and Sudan III. for fat. The osmic preparations were the less satisfactory since it was hard to distinguish fatty particles from pigment granules. The Sudan preparations, however, showed very well in places moderate fatty degeneration of the endothelium covering the alveolar walls. Sudan III. possesses the property of staining fat-droplets a golden yellow or carmine colour, according to the size of the droplet. In some places the alveolar walls were distinctly picked out by the stain, showing as a pinkish network. With a high power this was seen to be due to minute particles of fatty matter dotted throughout the endothelial plates. Certain of the desquamated mononuclear cells within the alveoli were loaded with fatty matter. Many others, and some also of the lining cells of the walls, contained pigment of a brownish colour, which was not fat but was apparently derived from the broken-down red cells. By the Gram-Weigert stain no bacteria were noted. By carbol-thionin certain of the bronchi were seen to be plugged

with exudate, the lining columnar epithelium being desquamated and in part degenerated. The exudate consisted in large part of oval or spindle-shaped mononuclear cells together with crowds of bacteria consisting of coccus forms and medium-sized bacilli having rounded ends. These bacilli varied much in length, some being very short, some were slightly curved, and others were bulbous at the ends. Most showed bipolar staining. Similar bacilli were present in great numbers in the collapsed areas. One small bronchiole was found to contain blood, an infarct having presumably burst into it.

Spleen: the staining agent used was hæmatoxylin. It was not congested and was without any special abnormality except some hyperplasia of the so-called epitheloid plates. The tissue was not œdematous and there was no perisplenitis. By the Gram-Weigert and carbol-thionin methods no bacteria were seen. Liver: the staining agent used was hæmatoxylin. The tissue stained fairly well and the nuclei were distinct. The cells were swollen and cloudy. No particular fatty change was observed and there were no hæmorrhages. Everywhere could be seen in the intercellular spaces within the lobules little scattered groups of two or three polynuclear cells. In the portal sheaths, by the carbol-thionin method, a small amount of acute interstitial infiltration could be made out chiefly along the course of the portal vein. These aggregations were not at all striking, however. In one or two sections also a few small lymphomatous masses could be observed consisting of small round mononuclear cells, with a few larger mononuclear hyaline cells resembling macrophages. No true focal necroses were noted. No bacteria were observed. By the Gram-Weigert method no bacteria were noted. Pancreas: hæmatoxylin was the staining agent used. Except that the tissue stained rather faintly there was nothing specially worthy of note. Kidney: hæmatoxylin was the staining agent used. Numerous areas of hæmorrhage were present both in the cortical portions and in the medulla. This hæmorrhage was marked in the interstitial substance in various places but was very strikingly shown in those parts where the blood had forced its way into the kidney-tubules, many of which were greatly distended with blood. In the cortical portion the hæmorrhages appeared to be most marked in the neighbourhood of the interlobular vessels running vertically forwards to the cortex. In one section a Bowman's capsule contained much blood and the glomerulus was distinctly compressed. The tubules, mainly the tubuli contorti, which contained the blood, were over-distended and the lining secretory cells were greatly flattened. In the medullary portion the straight and collecting tubules contained blood. Everywhere the extravasation was of recent appearance. Small, more wedge-shaped, masses were common just beneath the capsule. The glomerular tufts were not congested but the lining endothelial cells of the Bowman's capsules were swollen and occasionally desquamated. In a few capsules small masses of albumin could be made out. In the remaining parts the lining cells of the secreting tubules were swollen and granular-looking and the staining was defective. In the medulla and in one specimen surrounding a glomerulus and capsule near the cortex there was fairly extensive round-celled infiltration consisting of inflammatory leucocytes. The surrounding congestion was not great, however. The endothelium of the affected capsule was notably catarrhal. One of these infiltrated areas was large enough to suggest an abscess. A few small areas of round-celled infiltration were seen in some sections consisting of mononuclear elements and no doubt to be regarded as the so-called "lymphomata" of Wagner. The osmic acid and Sudan III. preparations showed practically the same features. There was a moderate degree of fatty degeneration affecting in some instances the basement membranes of the Bowman's capsules and very generally the secreting cells of the contorted tubules and the descending loops. Those tubules which contained blood showed this in a very extreme degree. The capillaries of the tufts were, as a rule, free, though certain of them showed slight fatty change. The sections stained by carbol-thionin showed that in the small inflammatory areas there were to be seen short, fine bacilli with rounded ends and with well-marked bipolar staining. By the Gram-Weigert method no bacteria were observed. The small intestine showed by the hæmatoxylin method marked catarrh of the mucosa, with some mucoid and cellular exudate upon the surface. The lining epithelium was swollen and the cells were active. The mucosa showed a moderate round-celled infiltration. On the submucosa the lymphoid follicles were swollen and proliferated, the epithelioid plates being specially numerous. The acute inflammatory infiltration extended through the muscular wall, round cells in considerable numbers being found between the various layers of muscle. The serosa was free. Small hæmorrhages were present in the submucosa and muscularis. The carbol-thionin method showed a few short bacilli with rounded ends and of moderate size imbedded in the mucus on the surface. None were seen in the deeper layers. By the Gram-Weigert method no bacteria were seen. The blood-vessels were examined very carefully in the lung, liver, and kidney with the view of ascertaining if any clots were present. The most that could be said was that in these different organs the blood in both arteries and veins showed a tendency to break down, the red cells being apparently converted into a fine granular material of pale brownish colour in which a few leucocytes were imbedded. Besides these there were certain large clear mononucleated cells which appeared to be swollen and desquamated endothelial cells. These endothelial cells of the small vessels and capillaries were everywhere more prominent than usual, a condition which has been described by F. B. Mallory[7] as a constant feature in typhoid fever, but found also in diphtheria and some other infectious fevers. Nowhere were definite fibrinous clots of emboli observed. The condition of alteration of the blood is one that we would lay no particular stress upon, for it is one which we have often seen in other cases, particularly in specimens which have been kept for some time in methylated spirit. Nowhere were bacterial emboli, acute arteritis, or phlebitis discovered. The arterioles and the larger vessels showed no histological peculiarities.

Bacteriological examination.—Unfortunately, through an oversight, cultures were not taken from the spleen or mesenteric glands. Agar cultures were made from the heart-blood, peritoneal cavity, and the kidneys. Small round pearly-white growths were developed in the peritoneal fluid. These were elevated and discrete; they proved to be cocci staining by Gram's method. They grew readily on all media, liquefied gelatin, coagulated milk, and produced acid. They were regarded as the staphylococcus pyogenes albus. From the heart-blood two varieties were isolated: the first was a thick, elevated, soft, moist growth of a whitish colour and the second was a thinner, more pearly growth, in the shape of more star-like colonies. These were isolated. The first variety were cocci, positive to Gram's method, giving all the cultural peculiarities of the staphylococcus pyogenes albus, and were identical with those found in the peritoneal fluid. The pure growth of the second variety showed a variety of forms, short fine bacilli with bipolar staining, pairs of oval short bacteria, cocci or single short ovoids. Some bacilli present were thicker than the others and somewhat swollen at the ends, apparently involution forms; when of full size the bacilli had rounded ends and were about four times as long as broad. No spores were seen. All were non-motile. These turned litmus milk red and coagulated it, although it took some time to do this. The coagulum was at first in the form of small flakes. It did not liquefy gelatin and did not produce gas in glucose broth. Inoculated into rabbits it proved to be non-pathogenic. Three forms were isolated from the kidney. The first conformed in morphology and cultural peculiarities to the staphylococcus albus. The second presented a variety of forms, short ovoids or cocci, bacillary forms about three times as long as broad with bipolar staining. They were non-motile and without spores; they did not liquefy gelatin and did not produce gas. Litmus milk was unchanged. They were non-pathogenic for rabbits. The third variety was a rather small delicate bacillus producing a greenish fluorescence. The chloroform test did not show any true pigment production. The bacillus was motile; it liquefied gelatin; it did not produce gas or acid and did not coagulate milk. Its reaction to the Gram method was uncertain. A rabbit inoculated through the auricular vein died six weeks later from purulent peritonitis. The original germ was not recovered, however, and the lesions found did not suggest the presence of the bacillus pyocyaneus. The rabbit probably died from some intercurrent infection, the bacillus coli being found in the various organs. The bacillus was finally regarded as the bacillus fluorescens liquefaciens.

The anatomical diagnosis was typhoid fever; typhoidal

A Hi tological Study of Typhoid Fever: Journal of Experimental edicine' 1898, p. 6111.

ulceration of the small, but principally of the large, intestine; general hæmorrhagic diathesis; mixed infection; multiple hæmorrhages from the mouth and nose, the bowels and into the skin, lungs, heart, spleen, kidney, intestines, bladder, gall-bladder, and connective tissues; small spleen; cloudy organs; acute diffuse nephritis; fatty degeneration of the capillaries of the lungs and kidneys; healed old duodenal ulcer; and right old pleural adhesions.

A careful scrutiny of this case shows that it was enteric fever, atypical in the particulars that the intestinal lesions were most marked in the large bowel, that the spleen was small, that there was a general hæmorrhagic diathesis, and that there was a mixed infection with the staphylococcus albus.

We do not think that the fact that the bacillus typhi was not found in the cultures invalidates the conclusion that the case was one of enteric fever, for the intestinal ulcers were characteristic for the age of the condition and the Widal reaction was positive, both facts together being practically conclusive. Owing to an oversight cultures were not taken from the spleen and mesenteric glands, and even if the bacillus typhi had originally been present in the kidney in such a situation it would be apt to be attenuated and would be the more easily overgrown by other forms of germ life. Further, it is notoriously difficult to obtain the bacillus typhi from the blood, so that a negative result in these particulars would have no special importance. Throughout the various organs there were the marked swelling and proliferation of the endothelial cells to which Mallory has directed attention. Altogether the facts above-mentioned, together with the histological appearances of the various tissues, are to our minds conclusive.

With regard to the cause of the extensive hæmorrhages we must conclude that one main factor was the fatty degeneration of the basement membranes of the capillaries and the various endothelial cells which was so noticeable in the case of the lungs and kidneys. It is, of course, possible to say that these changes in the kidneys were due to the acute diffuse nephritis which was undoubtedly present, but it is to be pointed out that the same condition was observed in the lungs where a true inflammation of the parenchyma certainly did not exist. The fact that in the alveoli of the lung in parts where there was no infarction the endothelial cells were desquamated in large numbers and very fatty goes to show very strongly that the condition was a primary one. No doubt, however, as the specimens of kidney clearly show, the fatty degeneration of the cells was most marked when there were extravasation of blood and pressure upon the cells, so that it is probable a vicious cycle existed as well. The slight alteration found in the blood within certain vessels, if not, indeed, an artefact, was certainly not sufficient to cause any blocking of the lumina. No thrombi, no emboli, bacterial or otherwise, were found nor was there arteritis or phlebitis. Further, there was at no time marked dilatation or insufficiency of the heart as in another of our Montreal cases.

As will be seen shortly, the development of hæmorrhagic manifestations in infectious and other diseases has been, upon histological and experimental grounds, attributed to a variety of factors. Many have sought for the cause in some local disturbance of the blood current, such as would be produced by acute arteritis and phlebitis, thrombosis, or bacterial emboli. In our case we have been unable to discover any conditions of this nature and can only conclude that in so far as any local cause was operative it is to be found in the fatty degeneration of the various endothelia and basement membranes. In what way this fatty degeneration leads to the condition of blood extravasation we do not feel able to say. There would certainly be weakening of the capillary walls, but our studies do not settle whether the hæmorrhages were per rhexin or per diapedesin. Great numbers of sections were examined, but in none could we find actual rupture of the capillaries.

With regard to the ultimate cause of the fatty degeneration, since we are able to exclude any inherited defect, such as hæmophilia or hypoplasia of the vascular system, and can further exclude any pre-existing state of malnutrition, scurvy, rheumatism, alcoholism, and cachexia, we can only refer it, not to any local action of bacteria, but to a condition of systemic intoxication and septicæmia. What particular germs were concerned in this it is difficult to say. The pathological investigation shows clearly that we were dealing with a case of mixed, or at least secondary, infection with the staphylococcus albus, and the history excludes the possibility of primary typhoidal purpura. No doubt all the micro-organisms present played a part in bringing about the degenerative changes, so that we are safe in referring these to the intensity and to the quality of the intoxication, which practically means to qualitative changes in the blood.

With regard to the frequency of the general hæmorrhagic diathesis in typhoid fever, all are agreed that it is very rare, although a petechial eruption, which is probably merely a mild type of the complication, is not so infrequently met with. Below we have tabulated all the large series of enteric fever cases which we have been able to find recorded.

Authors.	Clinic.	Total cases of typhoid fever.	General hæmorrhagic diathesis.	Purpuric eruptions.	Hæmaturia alone.

Of course, fairly numerous cases are met with in the literature in addition to the above, but they could not be included in the table since they did not form part of any extended series of observations. Examples, for instance, have been recorded by Trousseau,[16] Barlow,[17] Gerhardt,[18] Wagner,[19] Hawkins,[20] Hughes and Lévy,[21] Adami,[22] Nicholls,[23] Gilman Thompson,[24] and Hamburger.[25] It is possible that some of the cases are not examples of the condition under discussion, as many either occurred before the day of the Widal test or were not controlled by post-mortem examination. The following remarks are based upon a careful study of the recorded cases, any doubtful ones being neglected.

Etiology of the hæmorrhagic tendency.—Comparatively little is known as yet as to the causative factors in the condition. The few authors who have dealt with the subject confine themselves to general statements, nor do the various opinions expressed altogether coincide. A study of the cases recorded, however, goes to show that some of the etiological factors, so-called, have really little weight. A pre-existing scorbutic, hæmophilic, or rheumatic taint does not seem to have been noted. Alcoholism, on which Fereol and Roger[26] and Curschmann[27] laid stress, cannot be of

much importance. It was not present in any of Wagner's or our cases, though present in Gilman Thompson's and two of Curschmann's cases.

Others, like Gerhardt[28] and Griesinger,[29] regard defective nutrition due to scurvy, overcrowding, and scanty food as powerful contributory causes. The state of the previous nutrition, however, which on *a priori* grounds would seem to be an important consideration, does not appear to be a factor in all cases. Most of the cases recorded were in a previously healthy condition and some were of unusually good physique.

One of Wagner's cases was scrofulous in childhood and one of the Royal Victoria Hospital patients was puny as a child. A case under the care of Gerhardt had gone through an attack of measles three weeks before and the patient in Adami's case had had pneumonia and empyema. How far these factors were concerned in the subsequent development of the hæmorrhagic tendency is very problematical.

In this connexion the views of Gerhardt are of some interest. He thinks that the hæmorrhagic tendency has been more frequently observed since the introduction of the cold-bath treatment, and thinks further that a too rigid restriction of the patient to an animal diet is an important cause as tending to induce a scorbutic condition.

Leudet[30] in an epidemic which occurred at Rouen in 1869–70 lays stress upon a certain "epidemic influence," whatever that may mean.

Wagner has recorded a curious instance where a family idiosyncrasy seemed to play a part. Of five children in one family suffering at the same time from typhoid fever three developed a more or less pronounced hæmorrhagic tendency. That this was not due to poverty and malnutrition was shown by the fact that one of the sisters so affected was not living at home and was well nourished.

Wagner, Gerhardt, and Curschmann agree that the condition is commonest in childhood and early adult life. Of the cases recorded one patient was eight years and another was 16 years old. The vast majority were considerably under 25 years of age; the oldest was 32 years of age. The age average was 21·4 years. With regard to sex there seems to be an equal liability of males and females to the complication.

The type of the original typhoidal disease seems to be of some importance. The vast majority of cases are found in those suffering from typhoid fever of a severe form. The patients are much prostrated, the temperature is high, the heart's action is weak and rapid, and there may be coma or delirium. The mouth is usually very foul and the excretions may have an ammoniacal odour. In certain rare cases, as Curschmann points out, the hæmorrhagic diathesis may be one form of the "foudroyante" typhoid fever. One of our Montreal cases was, on the contrary, comparatively mild.

The character of the onset of the original typhoidal attack does not give any clue to the development of the hæmorrhagic complication. More than half the cases occurred in the ordinary gastro-intestinal type of the disease. In certain cases severe pains in the legs, rhachialgia, and cutaneous paræsthesiæ have been noted.

PATHOLOGY.

With the exception of the changes due to the special complication the necropsies show that the anatomical lesions differ very little from the ordinary typhoid. The anæmia is usually marked, as would be expected. Of 11 necropsies of which we have notes the typhoid ulcers were in two cases mainly confined to the large intestine, the ileum showing only very moderate involvement of the Peyer's patches. In Trousseau's case, where death occurred on the eleventh day, the Peyer's patches were softened but not ulcerated. In one of Wagner's, where death occurred on the thirty-ninth day, the ulcers showed signs of healing. In our own case the only feature of note about the ulcers was the extensive hæmorrhages into their bases and margins, giving them a much more red and swollen appearance than usual.

The spleen is, as a rule, found enlarged. The hæmorrhagic patches in the skin may be infected and break down, forming gangrenous ulcers.

Coming to the hæmorrhagic manifestations there is considerable diversity in their character and distribution. Hæmorrhage into a muscle, perhaps one of the slightest forms of the complication, is not very uncommon even in ordinary typhoid fever, but may be part of the general hæmorrhagic tendency. It is supposed to be due to a vitreous degeneration (von Zenker) of the muscle. The hæmorrhages may be minute, petechial, ecchymotic, or may form tremendous extravasations into all the loose tissues. Petechiæ may be present on the skin and all the mucous and serous surfaces. Parenchymatous hæmorrhages occur in the various organs. In fact, no organ or tissue of the body is necessarily exempt. Nor are the external manifestations of the condition a true index to the extent of the internal lesions, for, as Hamburger[31] points out, the most extensive involvement of the internal parts may be present when but little suspected.

The recorded necropsies show that the skin, subcutaneous tissues, and the various mucous membranes are by far the most frequently involved; next to them the lungs, spleen, and urinary organs. Infarcts have been found in the lungs, spleen, and kidneys, and thrombi in the renal and femoral veins, the chambers of the heart, the pulmonary artery, and the cerebral arteries. Curschmann says that embolism of arteries is very rare, but when found is usually in the kidneys and spleen. In certain cases the clotting of the blood has been undoubtedly ante-mortem.

With regard to the ultimate cause of the hæmorrhagic tendency but little is known; no cases have up to the present been studied with sufficient detail finally to settle the question, but, as already hinted, various theories have been propounded. Curschmann says: "We are uncertain what is the exact nature and mode of origin of hæmorrhagic typhoid, whether it is to be looked for in a certain peculiarity or activity of the typhoid germ or in some complication or state of the body."

The older writers supposed that there was some special change in the blood, a *dissolutio sanguinis;* but while this view has been ridiculed in certain quarters very little better has been proposed for it. Trousseau noted that the blood in "putrid hæmorrhagic fever," as in yellow fever, was of a dark colour and was deficient in coagulating power. This theory is interesting in connexion with Osler's case where the coagulation time of the blood was 10 minutes, sinking to four minutes during convalescence. No doubt this change in the blood is due to the character of the bacterial toxins present, for we know that in diseases like croupous pneumonia and acute rheumatism the coagulating power of the blood is increased. This seems to depend in part upon the number of the leucocytes present in the blood, for they are very abundant in pneumonia and rheumatism. Leucopenia, on the contrary, is the rule in ordinary uncomplicated typhoid fever. We would expect *a priori* that in typhoid fever during the acme the coagulating power of the blood would be diminished. The thrombosis of the crural vein which not infrequently is met with in typhoid fever is never seen during the height of the disease but invariably in the stage of profound asthenia and anæmia, when arterial relaxation and weak driving power of the heart are the rule. An interesting confirmation of this view is seen in a recent case of hæmorrhagic typhoid fever recorded by T. V. Openchowski[32] where the bleeding from the mucous membranes was very obstinate, not yielding to the usual remedies. Suddenly the blood began to clot and the hæmorrhage ceased. The next day signs of croupous pneumonia became manifest. On the contrary, in a case examined by Curschmann, no special external or histological peculiarity of the blood was observed. Further, neither hæmoglobinuria nor hæmoglobinæmia have been noted in these cases.

Any vitiated state of the blood must necessarily react upon the vessels and, arguing from what has been found in symptomatic purpura of other types, would afford a probable clue to the mystery.

Uskow[33] demonstrated swelling of the lining epithelia of the vessels in the gums and periosteum in cases of scurvy, and von Kögerer[34] has observed thrombosis of the vessels in the neighbourhood of the subcutaneous hæmorrhages in both scurvy and morbus maculosus Werlhofii.

Letzerich[35] in a case of purpura isolated a bacillus which when injected into rabbits produced widening of the capillaries with hæmorrhagic injection of the gums. Bacilli were present in the capillaries. The hæmorrhages were said to be due to hyaline plugs which were present at the bifurcation of the vessels. It should be remarked, however, that the presence of thrombi in the various vessels must be interpreted with caution. It is very possible that these

[35] Ueber Purpura Hæmorrhagica, Leipsic, 1889 (Vogel).

thrombi are due to the weak circulation and the relaxed and degenerated condition of the vessels which are present at the time of impending death. They are to be regarded as associated conditions rather than the true cause of the hæmorrhagic tendency.

In one case of purpura occurring in the course of acute endocarditis which we examined recently the subcutaneous tissues were found to contain large numbers of a rather slender bacillus in pure culture and both arteries and veins showed considerable acute inflammation of their walls with some surrounding leucocytic inflammation.

In sepsis and variola hæmorrhagica bacterial emboli have been found in the capillaries and give rise occasionally to ring-like hæmorrhages, particularly about the hair follicles.

According to Litten [36] these are not present in hæmorrhagic typhoid fever and this observation is confirmed by von Recklinghausen [37] and Meyer and by our own studies. It is probable that a variety of factors enter into the causation, a deficiency in the fibrinogen of the blood, together with relaxation and fatty degeneration of the vessel-walls. No doubt a feeble circulation may be an important element as in our first Montreal case, where the heart was much dilated and its action very rapid, together with cyanosis and coldness of the extremities. These conditions would certainly promote clotting of the blood and since old decolourised thrombi have been found post mortem the possibility of such an occurrence during life cannot be denied.

Numerous attempts have been made to connect purpura hæmorrhagica with bacterial activity. Klebs, Ceci, Jones, Tizzoni, Petrone, Babes and Letzerich, Hanot and Luzet, Widal and Therèse found streptococci; Lebreton and Litten found staphylococci in their cases. Hamilton and Yates [38] in a well-marked case isolated the staphylococcus aureus, the bacillus aerogenes capsulatus, and an unknown bacillus. Kenneth Cameron [39] has also noted a hæmorrhagic tendency in general infection in children with the bacillus pyocyaneus. It seems to us that this attempt to connect the hæmorrhage with the action of those micro-organisms found post mortem is open to fallacy.

Patients who are bleeding into the skin and mucous membranes are in the best of all conditions for bacterial invasion, and, in fact, we see this in those cases which develop abscesses or gangrene in various parts, as they often do. These cases no doubt die, not merely from the exhaustion of anæmia, but from septicæmia. When germs are found in the various organs post mortem under such conditions it is impossible to deny that they may be a result rather than the cause of the hæmorrhagic condition. Still, we know that in some cases bacterial emboli have been found in the vessels strongly suggesting a causal relationship, and to a certain extent the condition can be reproduced in experimental animals. Further, the absence of hæmophilia or other blood dyscrasia points strongly to the action of a bacterial cause. While, then, the bacterial origin of the hæmorrhagic condition is extremely probable the final proof is still wanting.

ONSET AND CHARACTER OF SYMPTOMS.

Analysis of the cases recorded shows that the hæmorrhagic tendency may occur at any time during the course of the primary attack. During the first week the condition is rare. In two cases recorded by Roger the hæmorrhage began on the third and fourth days and in one by Ferreol on the fifth. Such are undoubtedly cases of primary typhoidal purpura and strictly comparable to purpura variolosa and scarlatinosa. Griesinger remarks: "In all forms of typhoid, exactly as in small-pox, cases occur where very early, in the first week or later, abundant petechiæ and suggillations into the skin, sometimes into the muscles, set in; intractable nose-bleeding, ecchymoses, and bloody extravasations into the serous sacs, infarct of the lungs, bloody urine, intestinal hæmorrhages, meningeal and brain apoplexy, hæmorrhage into the connective tissue of the iliac fossa and formation of tumours." Cases are slightly more frequent in the second week and most common in the third week. The condition may occur during a relapse, as in Osler's case, or later in a protracted course, as in one of ours where it developed on the fortieth day.

[36] Die Hämorrhagischen Diathesen. Nothnagel's Specielle Pathologie und Therapie, Band viii., Thiel iii., 1898.
[37] Handbuch der allgemeinen Pathologie der Kreislauf und der Ernährung, S. 87, 1883.
[38] Montreal Medical Journal, August, 1897.
[39] Ibid., March, 1896.

The fact that most cases occur during the third week when the sloughs are separating from the ulcers is an argument in favour of the view that some at least of the cases are due to secondary infection. The recorded cases fall naturally into three groups: (1) primary typhoidal purpura; (2) purpura due to secondary bacterial invasion; and (3) cachectic purpura, occurring later in the disease or during convalescence. It is questionable, however, whether the third class is to be properly separated from the infective category.

The onset of the symptoms varies considerably. Sometimes, though rarely, epistaxis, melæna, or hæmaturia is the first symptom; generally, however, the first signs are in the buccal mucous membrane or in the skin. The hæmorrhages are generally multiple in distribution, petechiæ, bleeding from the mucosæ, hæmaturia, and epistaxis frequently going together. Hæmoptysis is met with and is due to oozing from the bronchi or to infarction.

The skin lesions consist of petechiæ or ecchymoses, the latter being sometimes of large size. If rose spots are present the eruption may take place into or between them. The petechiæ do not disappear on pressure. Sometimes hæmorrhagic pustules are present. Small bluish, elevated subcutaneous nodules are occasionally met with. In some cases a sort of diffuse subcuticular purplish mottling has been observed. The skin hæmorrhages have been known to occur into a bed-sore or on the application of cold. Gangrene may supervene and œdema.

No special symptoms seem to usher in the hæmorrhagic condition. Neither chills, sweating, nor a septic temperature seem to have been noted. Marked distension of the abdomen is not uncommon and diarrhœa is fairly frequent at the onset. The effect on the temperature is usually very slight, though in severe cases a gradual fall to subnormal has been noted, as in other cases of hæmorrhage. Profound anæmia usually develops. The hæmorrhage is not sudden, but rather a gentle oozing from all the surfaces of the body, and is apt to be precipitated by any slight injury.

PROGNOSIS.

The condition is generally very grave. About two-thirds of the cases recorded ended fatally. The previous history of the patient has some weight. As a rule the earlier the condition sets in and the more extensive it is the more serious is the prognosis.

TREATMENT.

Treatment is purely symptomatic. Gerhardt, in accordance with his views as to the etiology, discontinues the cold-bath treatment and substitutes a daily warm bath at a temperature of from 33° to 34° C. He includes potato, spinach, and vegetable juices in the diet. To control the hæmorrhage many plans have been tried. On the assumption that the cause is a secondary infection small doses of calomel or other mercurial have been given. One of our Montreal cases recovered under this treatment, as did one which was left alone. Turpentine and ergot were used by Gilman Thompson in his case which recovered.

Attempts have been made to increase the coagulability of the blood by means of calcium chloride as suggested by Wright.[40] In severe cases 15 grains should be given twice daily. This treatment has to be carefully controlled by repeated blood examinations, as if it is too vigorously pressed it may have the contrary effect to that intended. The same writer also advocates inhalation of carbonic dioxide. The effect of this was *nil* in Osler's case. Local applications of gelatin solution, tannic acid, or suprarenal extract may be tried. It is, however, very uncertain how far any of these remedies are efficacious.

From a study of hæmorrhagic typhoid fever and its relationships to purpuric conditions in general some suggestive ideas may be derived. On the whole it seems best to regard "purpura hæmorrhagica" not as a distinct disease entity but as merely a train of symptoms. Litten would restrict the term to the so-called "idiopathic purpuras," Werlhoff's disease, Schönlein's disease, purpura simplex, &c., and would deny it to that form met with in variola, typhoid fever, pernicious anæmia, leukæmia, sepsis, snake-bite, and some others. This, however, seems to be too narrow a view. The trend of modern pathological research, far from accentuating the divisions of the earlier clinicians, tends to show that the processes at work in all these different

[40] Brit. Med. Jour., Dec. 19th, 1891; vol. ii., 1893, p. 223; and vol. i., p. 237, and vol. ii., 1894, p. 57.

conditions are capable of unification. Most cases come under the head of "infections."

In the light of our present knowledge it would be better to speak (1) of an "essential" purpura hæmorrhagica, including under this term morbus maculosus, morbus Werlhofii, purpura simplex, peliosis rheumatica, and purpura urticans. Whether scurvy (purpura scorbutica) should be included in this class is perhaps doubtful, since "essential" purpura is a sporadic disease, while scurvy is apt to be epidemic and endemic. Some observers, however, would place scurvy with the others in the "infective" category. Babes particularly has described a bacillus which he thinks is the cause, but other observers have obtained negative results. Hæmophilia certainly should not be included in the first group, since it is characterised by family and hereditary peculiarities. It might be termed a "normal" condition for certain individuals and is not to be regarded as a true pathological state, since it is a permanent and not an incidental or transient condition. The second group might be termed (2) "symptomatic purpura" and would include all those cases which are met with in the course of the infective fevers, such as typhoid fever, variola, measles, scarlet fever, pest, yellow fever, sepsis, acute yellow atrophy, icterus gravis, &c. A third group might be termed (3) "cachectic," including forms found in pernicious anæmia, leukæmia, carcinoma, Bright's disease, &c. A fourth group is (4) the toxic purpuras, such as are met with in certain forms of poisoning, snake-bite, phosphorus, copaiba, antipyrin, &c. A fifth form is that found in (5) disseminated sarcomatosis, to which attention has been called by Martin and Hamilton,[41] where in one case which they studied there was actual sarcomatous invasion of the internal coat of the vessels and in another emboli of sarcoma cells. Whether these were the only factors or not seemed to be doubtful. The first two groups, and possibly the third, would fall under the head of "infectious" purpura.

THE TREATMENT OF TYPHOID FEVER.[1]

BY FREDERICK J. SMITH, M.D. OXON., F.R.C.P. LOND.,
PHYSICIAN AND SENIOR PATHOLOGIST TO THE LONDON HOSPITAL.

TYPHOID fever is a disease the ultimate etiology and pathology of which seem to be now pretty well worked out and understood, and the life-history of the bacillus typhosus, outside the human body, is rapidly becoming a commonplace of medical science; but I venture to think there is still plenty of room for discussion upon the best clinical treatment of the disease. I have for many years held an opinion that the lines laid down for our guidance in the matter have been laid down too strictly on the assumption that the intestinal lesion is the point to which our therapeutical measures must be mainly directed. That the intestine, or mouth at least, is probably in all cases the portal of entrance of the bacillus and that the intestinal lesions have very serious dangers of their own it would be idle for me to deny; but this paper is an offer to break an argumentative lance with those who hold that these dangers are entirely, or even in the main, due to departures from the routine milk treatment of our text-books of medicine. My statements are based upon my own experience of the disease both in hospital and in private practice and they are intended to have a practical value and bearing as well as to serve as a peg whereon to hang a discussion. I shall therefore consider the subject from the commencement of the illness and will strike at once the keynote of my ideas and contention, which is to object to the customary orthodox proverb that runs thus: "If the disease were only diagnosed early enough and appropriate treatment adopted many lives would be saved and much suffering avoided." The statement has a certain amount of truth in it, but it contains a great exaggeration and covertly throws on the profession as a body an undeserved amount of blame and obloquy, for the unspoken accusation is that any medical man ought to be able to diagnose typhoid fever at a glance and having recognised it that he ought at once to treat it on routine lines. With the first of these propositions I have, of course, nothing to do, though its absurdity is known to us all; it is with the second that my whole paper will deal.

An attack on the human frame by the bacillus typhosus goes through the usual stage of incubation followed by that of invasion, and most cases come under observation when the former is merging into the latter. The symptoms present are commonly headache of more or less severity, a general feeling of seediness and lassitude, a dirty tongue, and an upset of appetite and of bowel action, all probably coupled with some degree of pyrexia. Now such symptoms, and especially their ingravescent persistence, are in themselves absolutely pathognomonic of the necessary treatment—viz., bed. This is the only place where a patient presenting these symptoms ought to be, and provided we have insisted with sufficient authority on this one item of advice we have for the moment done all in our power to mitigate the severity of the attack which may be coming on. Whether the patient follows our advice and goes to bed or not, we usually consider that he will be the better for having the primæ viæ cleared out, and accordingly few of us resist the temptation to treat such a patient, probably with a blue pill, and certainly with a saline aperient. Now I hold very strongly that such a treatment cannot possibly have any ill effect if too violent a purgative, such as croton oil or elaterium, be avoided, even should the case ultimately prove to be one of typhoid fever. Again, if, on the one hand, the patient feels so ill that he follows our advice and goes to bed he will as a matter of routine be put upon bed diet—viz., milk or bread-and-milk, beef-tea, soup, or cups of tea with bread-and-butter or dry toast; if, on the other hand, the symptoms be so mild that he neglects our advice and does not go to bed his appetite will still be so poor that he is not likely to take food enough to incommode the intestines. In either case I cannot conceive that the food, either by quantity or quality, can be in a position to inflict any mechanical injury on the intestine, for it is inevitably reduced to a pulpy condition before it leaves the stomach, and the intestines are not yet in that dangerously ulcerated condition which they may later assume; hence, neither by drugs nor by food is the patient in this early and possibly doubtful stage likely to be harmed. If harm does really accrue from neglect in this stage it is, I believe, entirely, or at any rate mainly, due to the attempt of the patient to get about and do his work while the microbes are multiplying in him, and his organs, the heart especially, are being wasted by pyrexial oxidation and poisoned by foreign toxins of a most deleterious character. It is this which makes bed such an imperative point in treatment.

I will now pass on to the cases where the diagnosis is certain and the disease is fully developed. I may incidentally mention that statistics will take no part in my argument. Statistics have their uses, but when we are considering the why and wherefore of a given patient's death our minds turn to the question, Could I have averted this catastrophe by any alteration in my plan of treatment? The patient, or his body, is before us as an individual case with its own secrets and interests, and not as a unit in a row of figures with some subtle paper relationship to percentages. I shall mention one or two cases that I have watched with the deepest interest. Now, in the treatment of such cases there are, in my opinion, two general principles of such overwhelming importance that I must deal with them first in general terms and later come to individual points: they are (1) the examination of the stools; and (2) the appetite of the patient.

EXAMINATION OF THE STOOLS.

I lay it down as a golden rule from which no exception should be made that one stool at least must be carefully examined in every 24 hours during the active course of the disease. In my hospital cases, where special facilities exist, I wash a stool through with running water in a large glass vessel. In private houses this is rarely practicable, but the stool even here should be carefully stirred about with something (that can be burnt) so that its composition may be investigated. In the stools may be found (1) obviously undigested milk or other food; (2) blood; (3) sloughs; and (4) mere feculent débris.

1. *The presence of undigested milk or other food.*—This I take to be at once conclusive proof that more milk or other food is being given than can be digested and is an absolute indication that the quantity must be considerably diminished. My own plan is to stop *all* food absolutely for 24 hours and then begin with very small quantities indeed, and if it be

[41] Journal of Experimental Medicine, vol. i., No. 4, 1896.

[1] A paper read before the Medical Society of London on Jan. 28th, 1901

milk curds that are found I prohibit that article altogether in its natural raw state.

2. *Blood.*—If this be visible to the naked eye and yet is present only in small quantity it is an indication that the intestinal lesions are of considerable severity, and it serves more to cross the *t* and dot the *i* of caution than to give any special line to treatment; but if it be present in large quantity it gives the strongest indication for the free exhibition of opium, say 10 minims every two hours for eight or 10 doses, or until the patient is drowsy, and for the stopping of all food absolutely for 24 or 48 hours so as to give as complete rest as possible both to the mind and to the intestine.

3. *Sloughs.*—These by themselves and without blood in quantity merely indicate a natural state of affairs in a case of considerable severity about the third or fourth week. They make us anxious lest hæmorrhage should supervene and suggest starvation or caution in feeding for a day or two, and their total bulk is a matter of some importance as indicating the extent of the ulceration.

4. *Feculent débris.*—This is the desirable constituent of the stools, and the more they consist of this and the less we are able to discern of the other named elements the stronger the indication to persist in the line of treatment which we have adopted.

THE APPETITE OF THE PATIENT.

I am sufficiently teleological in my opinions to hold very firmly that in the economy of nature appetite means the readiness of the stomach for food as well as capability of that organ for dealing with appropriate articles put into it. (I am not here dealing with the pathology of dyspepsia, which undoubtedly seems to offer many apparent exceptions to the above rule.) I have, therefore, in typhoid fever long made it a cardinal rule to allow the appetite of the patient to be, within very wide limits indeed, the sole arbiter of his diet, provided that vomiting, hæmorrhage, or distension of the abdomen are all absent. The temperature I entirely ignore in the matter, feeling absolutely certain that if the wish for the food exists the stomach is clean enough and strong enough to deal with the articles enumerated below, so that what gets into the intestines will do no mechanical damage to the walls of that viscus. While thus stating so emphatically my belief in a liberal dietary when appetite asks for it and other circumstances allow it I must equally emphatically present the other extreme—viz., that in which appetite is completely in abeyance. I am quite confident that during the active ingravescent stage and the height of the fever the digestive function of the stomach is absolutely stopped, and probably that of the intestine too. Experience in the post-mortem room of full stomachs has convinced me very strongly of the truth of this dictum. I am sure that the only food that can during this time be dealt with, as it is the only food craved for by the patient, is plain cold water. We are very much afraid of thus starving our patients—too much so, I am sure; for though we may lead a horse to water we cannot make him drink, and so we may pour food into the alimentary canal, but we cannot make it digest or absorb; nature starves the patient if we do not, witness the universal wasting in all severe cases of enteric fever; and the food we put in only travels slowly on, decomposing as it goes, and causing discomfort if not threatening actual danger, and the idea of feeding the patient in the so-called typhoid stage—dry brown tongue, semi-delirium, &c.—on anything but water is to me repugnant in the extreme. It may naturally be asked how long would I keep on this water treatment. I cannot speak definitely as to limits, but I can say that I have kept it on for as long as four or five days with the happiest results and have never regretted doing it for too long a period, though once or twice I have wished that I had persisted in it for a day or two more. The wish of the patient for food—in other words, his appetite—has hitherto been my sole reason for stopping it of my own will, though I have reluctantly yielded to the solicitations of friends who feared that the patient would die from exhaustion.

DIET.

Having now discussed the influence of appetite in general we may proceed to particular articles of diet in brief detail. Milk I must place first, because as a basis for diet it must remain my sheet-anchor. I strongly object to its being given in any bulk in its natural raw state. It forms a tough ball of curd in the stomach very likely to start vomiting. It should always be given in a form in which this balling and curdling are avoided—e.g., as liquid custard (the yelk of five eggs beaten up with a pint of milk, sugar and flavouring added, and the whole thickened by scalding short of the boiling point); or as baked custard pudding broken up fine with a fork; or as junket; or as the basis of cocoa, of coffee, or tea, or of bread-and-milk; or with rusks soaked in it and beaten up with a little baked fruit pulp, according to the wish and appetite of the patient; or as milk puddings with ground rice, sago, tapioca, &c., well cooked. Eggs lightly boiled or poached I would allow in any stage, at least the yelk spread on bread or a rusk. Jelly and soups flavoured to taste are often very grateful to the palate. All the genus of commercial foods are, I think, of very doubtful nutritive value. The processes incidental to their manufacture on a commercial scale and to their preservation in bulk are what I suspect and I much prefer beef-tea made as follows. Take half a pound of lean beef cut very small, better if passed through a sausage-machine; place this in a small pie-dish, add half a pint of cold water, a pinch of salt, and a few drops of vinegar. Allow the whole to stand cold for two or three hours, then warm it slightly and strain through muslin or even squeeze with a lemon squeezer. Or we may give the beef-juice obtained by quickly cooking a steak over a very hot fire, splitting it open, and scraping it with a sharpish spoon so as to obtain tiny fragments of muscle with the juice. Meat and fish must be either put through a sausage-machine or minced as fine as possible and pounded in a mortar. Bread (very stale, at least three days old), rusks, and plain biscuits of all sorts may be given, either soaked in milk or, if the patient prefers it, he may nibble at such to give his jaws a little exercise. The dryness of the article prevents it being swallowed before it is well softened by saliva. Beer or stout as a stimulating food I should never deny to a patient who asked for it, but other forms of alcohol, given purely as stimulants, come, I think, under the heading of drugs to be used for emergencies. In the typhoid state of a patient who is accustomed to beer and likes it I believe in substituting bottled beer for water as the sole food to be given. The only articles to be avoided are those which may leave small hard particles after leaving the stomach, such as raw fruit, especially apples (their pips), orange-pips and pulp, and grapes (whole)—the juice I have no objection to.

These are examples of the usual available foods; we must now consider the quantities in which, and the times at which, they may be given. In the days when the disease is definitely present and yet the patient is quite conscious and willing to take food I would give him, say at 8 A.M., a cup of milky tea, coffee, or cocoa, or of bread-and-milk, according to his predilection; at noon two tablespoonfuls of crushed meat or fish; at 4 P.M. two ounces of custard or custard pudding; at 8 P.M. the food of his breakfast could be repeated; and at midnight or 4 A.M. the bread-and-milk or any of the other items, if the patient is awake. The patient, however, should never be awakened for the purpose of administering food. Sleep is, I am sure, of more value to him than food in the stomach. Between the hours I have named nothing should be given but plain cold water, or hot water if the patient prefers it. This is an ample supply for any patient during the ingravescence and height of the disease, and during this time even if there be some wish for more food I think we should do better to hold our hands. If the patient becomes unconscious or semi-delirious and the tongue dries and becomes dirty I think the quantity should be diminished and water substituted for two or three of the meals; but, *per contra*, as soon as the height of the disease has passed we should be ready to allow more latitude, according to the patient's feelings, provided that there be no indications to the contrary. These will appear either in the stools, the indications of which I have already mentioned, or in the shape of some complication of the disease, the treatment of which I will now proceed briefly to discuss.

COMPLICATIONS.

1. *Vomiting.*—This is a very exhausting act and is to be avoided in typhoid fever by all possible means. I believe it to be invariably due to putting food into a stomach which has no desire for alimentation, and hence it usually arises from routine feeding against the feelings of the patient. On the first indications of nausea after food resort should be at once had to the plain water diet for 12 hours, and longer if necessary; if it still persist I think a little hydrocyanic

acid and bicarbonate of soda with solution of bismuth the best, as they are the usual and simplest remedies.

2. *Tympanites.*—This, whether as a natural result of perforation and peritonitis or as a complication by itself, I consider to be the complication of typhoid fever which is of most ominous significance and the most difficult to treat. In the former case there is, of course, little to be said or done; surgery, I believe, offers the one sole chance of recovery, and that but a poor one indeed. In the latter case—i.e., standing by itself—there is a good deal to be said about it. As regards its causation, I believe that in some severe cases it will make its appearance despite our most careful attention, and then it requires to be treated as below. But I have a strong suspicion, however, that in the majority of cases it is a complication that arises from improper dieting. Hence I never feed a patient by routine, contrary to his feelings. When the fever gets higher and his feelings give us less guidance I think that a few grains of pepsin or other gastric digestive powder may be given with each meal, but I strongly disapprove of peptonising the food beforehand, as we cannot tell whether our processes are those which the stomach would like its food to undergo. Thus far prophylaxis in general; but we can carry this a stage further: at every visit the hand should be placed gently on the abdomen and careful palpation should be performed. It is thus possible to detect the very earliest warning of the onset of tympanites. The slightest tendency to rigidity of the abdominal muscles or the slightest convexity of the abdomen over its natural condition sounds at once a note of suspicion, and on the discovery of either we should immediately stop all food except water. My own plan is to administer at once two drachms of sulphate of soda in warm water every two hours till the bowels are acting freely. The complication, I believe, most commonly arises when there is constipation, but even if there be diarrhœa investigation will show that the stools have but little feculent débris, and I believe the saline aperient is still the best treatment. I usually, too, order an ice-bag to be placed on the abdomen and resort more persistently to chlorine water or salol as antiseptics. I cannot call to mind having a case of tympanites where the patient has been under my own care from the commencement.

3. *Constipation.*—This is a condition of the bowels which I never allow to persist and the only question is what purgative to employ. All my patients are on admission, as a matter of routine, put upon one grain of calomel at least once a day, and sometimes twice. This has a slight antiseptic action and is a very safe laxative. If, however, in spite of this the bowels are not open at least once in every 12 hours my house physician has instructions to administer sulphate of soda in two-drachm doses every two hours till the bowels act, a simple enema being also administered to attempt to clear the colon and to prevent a *vis in fronte*. I have seen several cases improve remarkably upon this line of treatment. I have never had cause to regret adopting it, but I have regretted a want of courage to adopt it in some of my earlier cases when I was feeling my way to such unorthodoxy.

4. *Excessive diarrhœa.*—I have seen so little of this that I hardly feel competent to say much about it. From six to eight motions a day come quite within the natural history of most cases which ultimately recover. If the stools become more frequent than this they should be personally inspected with the greatest care and suspicion, and I believe that they will almost always supply the clue to the cause of the excess—either milk or food grossly and obviously undigested or much sloughy material from the bowel and large quantities of mucus. In the former case the line of treatment is obvious—viz., to stop all food but water; in the latter case my experience in the post-mortem room suggests that the cause is extensive ulceration of the colon, for this is what I have found in nearly all the cases upon which I have performed a necropsy—apart from perforation and peritonitis. I have therefore been led to regard excessive diarrhœa not due to feeding as a very fatal complication. I tried in one case, with a satisfactory result, an enema containing two drachms of tincture of opium, one ounce of subnitrate of bismuth, two drachms of powder of ipecacuanha, one ounce of starch, and hot water to one pint, so that I should be inclined to try a similar injection in future.

5. *Pyrexia.*—In ordinary cases this is best treated, I think, by tepid sponging. I confess that I do not like the idea of cold baths, but in one case at least where the temperature was very rebellious and threatening I distinctly believe that I saved the patient's life by continuous immersion for nearly three weeks in a bath maintained at 100°F. or a degree or so lower—at any rate, I considered her *in extremis;* I kept her in the bath and she ultimately made a good recovery, and the impression of all who saw her was that it was the bath that saved her.

6. *Hæmorrhage.*—This I have already considered in speaking of the stools; I mention it again to emphasise my opinion that if starvation and opium are found to be useless I believe that nothing else is of the slightest use. Lead and tannic acid I am sure never reach the bleeding spot, and ergot is worse than useless unless it be administered in doses which I should be frightened to try.

DRUGS.

No disease offers less chance to continuous routine drug treatment than does typhoid fever, and yet for all that I must admit that I have a preliminary routine treatment for all cases. It consists of two grains of calomel immediately and then one grain every night, and a mixture containing carbolic acid or chlorine water; or else I give 10 grains of salol in powder three times a day. I have a good deal of faith in these measures. The calomel acts slightly against any tendency to constipation and also as a mild antiseptic, and the other drug is probably useful from its antiseptic properties; such, at least, is my belief, though it is very difficult to account for their good effects upon scientific grounds, for they certainly do not render the stools completely aseptic. I can only assume that in some way the antiseptic derivatives of tar do antagonise some of the particular products of the bacillus typhosus which are most troublesome. Of other drugs I practically use none as a matter of course, reserving them for emergencies in the manner which I have mentioned under each heading.

I cannot leave the question of drugs without mentioning alcohol. This I believe to be unnecessary for the treatment of typhoid fever; but for the treatment of the patient I think that a little may be allowed to those who are in the habit of taking it, and, generally speaking, in that particular form to which they are accustomed. I am particularly fond of allowing a glass of beer, for to the lay mind a glass of beer has no associations with the dietary of the sick, and hence the permission to have one at once rouses them to the impression that they have a good chance of recovery, and this impression is a most valuable one to elicit and to keep up.

Of the details of nursing it is not my province to speak at length, but I would mention the importance of the medical man himself inspecting the buttocks, &c., to see that they are kept scrupulously clean. I am constantly in the habit of ordering a specially long flannel night-gown split all the way down the front and back and tied with tapes. This is the most comfortable form of clothing that I know of for all patients who are in bed and likely to be there for some time. It is at the same time the easiest for the nurse to manage so that free access can be gained to all parts of the body, and it is the easiest to replace and renew. It is such a contrast to the tight-fitting vest, sodden with sweat and probably with dirt, that I so frequently find clothing the person of patients in bed.

The mention of the treatment of typhoid fever would obviously be incomplete without reference to the method of anti-inoculation. This is, I believe, destined in the future to become the universal method (? for prophylaxis also). At present I am personally obliged to leave it with simple mention, but I am in hopes that in the discussion which may follow someone may take it up more fully—someone who has tried the method and has some results to show. The obvious analogy with diphtheria almost compels us to feel certain that it is only improvements in methods of technique that are required.

In conclusion, I would beg to repeat that the less of routine feeding there is in treating typhoid fever the better; each case must be taken on its own merits and indications. I cannot claim infallibility for my methods, but I believe that their results as regards mortality are at least as good as those of any other plan and I feel sure that strength is better maintained and that convalescence is more endurable and rapid. Relapses do occur with my plan as with others, but I feel very little anxiety with regard to them, for the patient has as much strength as his primary attack can possibly allow him to have.

Harley-street, W.

FILATOW'S SPOTS IN MORBILLI.

BY L. FALKENER, M.A., M.D. CANTAB., D.P.H.,
LATE ASSISTANT MEDICAL OFFICER, METROPOLITAN ASYLUMS BOARD.

IT seems now to be generally recognised that the special spots first discovered by Filatow in the mouths of patients suffering from morbilli are pathognomonic of the disease. Filatow described them in the third edition of his work, "Acute Infections-Krankheiten," in 1895. Previous to this Flindt in *Sundhedskollegiets Aarsberetning* for 1880 had described certain spots on the palate and on the buccal mucosa, but he does not seem to have correctly distinguished these particular spots After Filatow Koplik described the spots in *Archives of Pediatrics*, December, 1896, and since that time they have usually borne his name.

Filatow's spots appear as very fine white specks. Koplik, however, describes them as bluish-white, but most observers will probably agree with Filatow in considering them to be white. In size these spots are often quite minute and require a strong illumination for their recognition; at other times they are three, or possibly five, times as large and are then very readily distinguished even with the reflected light of an oil lamp. On rubbing the spots with the handle of a teaspoon it will be found that the white substance of which they are composed is not at all easily removed. Around each spot is a red areola. On the first day of their appearance the red areola may, however, occasionally be absent, and it will then be very difficult, if not impossible, to make a confi dent diagnosis. Fortunately, however, the appearance of the white speck is very shortly followed by that of the red areola, the spots thereby becoming distinctive. At first the spots may be very few in number, perhaps only one or two, this being especially the case on the first day and the last day of their appearance. In some cases even throughout the whole course of the attack only a small number may present themselves; thus, in one of my cases four was the greatest number which were ever visible at any one time throughout the disease, but in others they become so numerous that the whole of the areas affected may be covered with them. These little spots consist of fine papillæ, the epithelium of whose summits has become pulpy and whitened, whilst the papilla itself and the area of mucosa immediately surrounding it have become hyperæmic and slightly swollen, so that one gets the appearance of the white speck surrounded by the red areola. Filatow clearly took this view of their nature. Certain observers have, however, erroneously described them as vesicles. In cases in which this exanthem is very abundant the individual specks may lie in such close apposition that the white substance of contiguous specks may coalesce, thereby forming spots of a size unusual for Filatow's spots and raising in one's mind a suspicion that they may be due to some form of stomatitis other than the kind in question. This suspicion is, moreover, often strengthened by the observation that the white substance is in these conditions often much more easily erased, thereby increasing the resemblance to some of those forms of stomatitis which are met with in the early stages of scarlet fever and other febrile conditions. Fortunately, however, even in the most abundant eruptions of Filatow's spots a very large number remain discrete and facilitate the diagnosis. The hyperæmia and swelling of the mucosa which, as above described, appear around each speck, rapidly extend, so that the general surface of the mucosa becomes increasingly reddened. At one stage this often presents a macular arrangement, constituting an appearance that has often been noticed in morbilli and which was at one time held to be pathognomonic of the disease. In many cases the reddening extends over the whole mucosal surface, rendering it uniformly injected; upon this injected mucosa Filatow's spots may still be visible. Filatow's spots when they disappear generally do so with great rapidity. They are often present in moderate abundance on the one day and entirely absent on the next, for when the substance constituting the white speck is cast off all trace of the original existence of a Filatow's spot disappears, the site of a spot then presenting no optical character which distinguishes it from the rest of the mucosa.

The commonest site for Filatow's spots is the buccal mucous membrane and on this they have a partiality for certain localities. If the spots are few in number the most likely place to find them is opposite to, and on a level with, the bases of the lower milk molars on either side; in this place they often form a small cluster. Another very favourite locality is the corresponding situation with regard to the upper molars; here also a cluster may be seen. Another position is opposite to the line of junction of the upper and lower molars when the jaws are closed; here they are frequently distributed as a somewhat straggling line. At other times they are more or less evenly disposed over the mucosa in greater or less profusion. After the buccal mucosa the inner surface of the lower lip is the part most commonly affected. In this locality, however, less white substance is usually present at the summit of each spot, so that the recognition of the spots is more difficult. The spots are best seen close to the fornix of the lip and the jaw. The third commonest site is the inner surface of the upper lip, this site being far less frequently affected than the preceding. Certain other localities also are occasionally affected. Amongst the 76 cases which I have observed there were three in which Filatow's spots were distinctly seen to be invading the gum of the lower jaw. In two of these cases they were in great profusion and in one of them they were noticed to extend up to the very margin of the teeth. Filatow's spots may also be seen on the buccal mucosa as far back as its posterior limits, and in some of my cases they were noticed to be present on the bridge of mucosa which passes on each side between the upper and lower jaw at the back of the posterior molars and which connects the cheek with the soft palate. In this situation they were present in ten cases. The spots may also occasionally be found on the soft palate itself; thus, in two cases they were readily visible on the soft palate for the distance of from a third to a half of an inch within the inner margin of the teeth, and in a third case they extended still further. In this particular case—that of a child aged nine years—Filatow's spots were far more numerous than in any other case that I have seen. They were in the greatest profusion on the buccal mucous membrane and the inferior and superior labial mucosæ; they were in great profusion on the mucosa of the gums and the "bridges" above described, and they extended in profusion over almost the whole of the soft palate and the uvula. On the palate they were most numerous in the neighbourhood of the fauces. In this case they were also present on the under surface of the tongue; here the spots were only three or four in number but they presented so typical an appearance that their identity was beyond dispute. Sobel is the only writer, so far as I am aware, who also describes them in this position.

The age of the patient seems to have no controlling influence; they have been seen in the mouths of adults as distinctly as in those of children.

With regard to the time at which the spots first appear, Filatow isolated a case six days before he saw the exanthem. Knöspel, in describing his 41 cases, says that he found Filatow's spots in one case five days, in six cases four days, and in three cases three days before the exanthem. Maroney amongst 140 cases of morbilli observed the spots in two cases four days, in four cases three days, and in 20 cases two days before the exanthem. Maroney amongst 140 cases of morbilli observed the spots in two cases four days, in four cases three days, and in 20 cases two days before the exanthem. Koplik cites 16 cases and amongst these the earliest appearance of these specific spots of Filatow was three days previous to the rash on the skin. Amongst my own 76 cases they occurred in nine cases three days before the exanthem. I have never seen them earlier than this.

My list of 76 cases comprises those consecutive cases of morbilli dating from May, 1898, to the present time that came under observation at a period in the disease at which one could reasonably expect the specific spots to be present. These spots have their own definite periods of appearance and disappearance with relation to the general course of the disease, just as is the case with the exanthem, and it is therefore interesting to look over this list and study the dates of these occurrences. Thus amongst my 76 cases I find that on the fourth day preceding the exanthem five cases were examined and that in none of them were the spots seen; that on the third day 19 cases were examined with a positive result in nine; that on the second day the respective numbers were 26 and 19; and that on the day immediately preceding the exanthem they were 33 and 33. On the first day of the exanthem they were 57 and 57; on the second day they were

59 and 54; on the third day they were 60 and 30; on the fourth day they were 58 and 10; on the fifth day they were 57 and four; and on the sixth day they were 57 and 0. It will thus be seen that whenever my cases were examined on the day of the first appearance of the definite onset of the exanthem (as apart from premonitory rashes) and the day preceding it these specific spots of Filatow were invariably present. It will also be noticed that the incidence for cases examined on either the second day of the exanthem or the second day preceding the exanthem was 75 per cent.; whilst for those on the third day of the exanthem or the third day preceding it the incidence was 50 per cent. Amongst my cases whenever Filatow's spots have persisted up to the third day of the exanthem they have nearly always by that time become very much diminished in numbers, and frequently in definition; whilst on the fourth and fifth days they were often barely distinguishable, and were in several cases far from typical in appearance. I have never seen them later than the fifth day. In most cases they disappeared earlier than the exanthem, but in one or two cases both spots and exanthem disappeared simultaneously.

I may mention that every one of my cases exhibited Filatow's spots. My figures, therefore, are 76 cases with Filatow's spots present in 76; Koplik's, 16 and 16 respectively; Sobel's, 35 and 35; Slawyk's, 52 and 45, but seven, he states, were not sufficiently carefully examined for the spots; Rolly, 78 and 67, or 74 and 67 if four are excluded where the patients had the exanthem when first examined; Finkelstein, five and five; Libman, 50 and 50; and Maroney, 140 and 132. Knöspel saw the spots in 41 cases, but he does not state if these cases were all consecutive.

Certain writers have said that the differential diagnosis of Filatow's spots from others which are found in the mouth is always an easy matter, but with this I cannot agree. In the first place, as above described, the spots during the first few hours of their existence may lack the red areola, and without this important characteristic no diagnosis of Filatow's spots can be secure; and in the second place, in the formation of the diagnosis the following conditions must always be borne in mind. 1. Certain spots of a permanent nature are often present on the buccal mucosa. These, when present, are papules of about the size of a medium-sized Filatow's spot; they are, however, quite inerasable and in colour are always yellowish instead of white, and consequently when once distinguished should no longer give rise to trouble. 2. One writer (Rolly) says that small curds of milk form the only real difficulty; this should not be so, in that curds of milk would not be fixed to the mucosa at all, whilst Filatow's spots are firmly adherent. 3. In thrush the spots are so large and the distribution so anomalous for Filatow's spots that there is no difficulty in distinguishing the two conditions; thrush occurring so often over the soft palate, on the tonsils, and on the dorsum of the tongue—situations for the most part unaffected by Filatow's spots. 4. Aphthous stomatitis to my mind is the only great difficulty in differential diagnosis. Of course, a large plaque of stomatitis is easily excluded, as, for instance, the plaque so often seen on the buccal mucosa level with the first molar teeth; but smaller spots of stomatitis, and especially the small fugitive ones so often encountered at the commencement of febrile disorders—e.g., scarlet fever—and which vanish within a few days, sometimes offer great difficulties in diagnosis from Filatow's spots, especially on the first day of their appearance. The principal differences, however, are these. Small aphthous spots are usually much more readily erased with the handle of a teaspoon; they often lack the red areola; some of them are often too big, thereby casting doubt on the others; they are usually too opaquely white for Filatow's spots; and, besides these points, ulceration is often present at their bases.

With regard to the absence of Filatow's spots in diseases other than morbilli Sobel states that for two months in 1898 he took special pains to examine the buccal mucosa of children affected with various skin eruptions, and that amongst the 1000 cases he examined during that period he in no case found any spots of a similar nature. To this I can likewise bear witness, for during the last two and a half years' practice at a fever hospital I have paid special attention to this point, and excluding the presence of morbilli I have never seen them in any of the 3000 or 4000 cases which I have examined during that period.

As a definite means of diagnosis I would especially lay stress on the utility of these spots in the following conditions where the diagnosis is often notoriously difficult. 1. Rötheln is perhaps the disease or condition *par excellence* that simulates morbilli, and it is therefore the one in which the greatest difficulty in differential diagnosis occurs. Filatow's spots are invariably absent in rötheln, and with this statement all writers on the subject are agreed, so that by means of these spots one can accurately separate the two diseases if seen on the appropriate days, and one can await the evidence of subsequent events with composure. Of rötheln I have seen 31 cases since May, 1898, and in none of them were Filatow's spots present. I may add that I saw all of them from the beginning of the exanthem. 2. When laryngitis occurs in morbilli before the exanthem and is of a very decided character, with much croup and recession of the chest walls, the case is liable to be certified and sent to a fever hospital as one of laryngeal diphtheria; but if on examination these spots are seen one can at all events be quite sure of one thing, and that is, that whatever else the child may have it most certainly has morbilli, and it was by means of Filatow's spots that the six cases of this nature admitted into the hospital with which I was associated since May, 1898, were all correctly diagnosed on admission as having morbilli, much as the other symptoms seemed to point against it. In one of these cases the exanthem did not occur till two days after admission, in another case until two and a half days, and in the other four till three entire days had elapsed. I may add that in not one of these six cases was diphtheria present. 3. Of the condition of morbilli sine eruptione one of my cases was a very striking and undoubted example. The patient was the last unprotected case in a ward ravaged by morbilli who had not contracted the disease. On Nov. 21st, 1899, he presented typical early symptoms of morbilli. His face became slightly puffy, he was irritable and drowsy and resented any disturbance, and he had a distinctly morbilloid cough, thin rhinorrhœa, increased salivation, and a very noticeable morbilloid odour of the breath. There was no lacrymation, no rise of temperature, no exanthem, and no Filatow's spots. On Nov. 22nd there was one very small and ill-defined Filatow's spot on the left buccal mucosa; also a nondescript white spot further back. On Nov. 23rd the child was very much better; he looked lively again and the cough had disappeared. Four very definite Filatow's spots were present on the right buccal mucosa, clustered about one site. On Nov. 24th no Filatow's spots were visible, and on Nov. 28th no exanthem had appeared at all, although very carefully searched for, and the boy was quite well again. Such a case as this, without the pathognomonic sign, would generally leave one in a very doubtful state of mind as to the correct diagnosis; but when one has well-marked morbilloid symptoms, associated with the presence of these spots of Filatow, I think one can rest quite assured that the case is most certainly one of morbilli, in spite of the complete absence of any exanthem. Maroney cites two cases of a similar nature, except that instead of being mild they were fatal attacks. Further observation of the spots may settle the question as to the existence of measles without catarrh, which is at present in dispute. 4. It is well known how very closely some antitoxin rashes and erythema multiforme from other causes simulate morbilli. It is true that catarrh may be more or less completely absent, but still the rash itself may be so very suggestive that if one did not have these spots to fall back on, one would frequently on first seeing the patient be left in some little doubt about the case. Filatow's spots are invariably absent in these cases.

I need hardly point out the great importance of Filatow's and Koplik's discovery from a practical point of view. It is important in that it enables one to accurately distinguish morbilli from certain conditions in which the diagnosis would otherwise be very difficult or beyond our powers. It is also important in that it enables one to check outbreaks of morbilli in households, hospitals, schools, or other institutions by the early isolation of those affected. In the case of schools it has been attempted to stamp out epidemics by notification on the part of schoolmasters and others; but this plan, unfortunately, has hitherto met with little or no success, in that the cases have for the most part been distinguished too late. The method of diagnosis hitherto most commonly in vogue has been by means of the exanthem, but by the time of the appearance of the exanthem catarrhal symptoms are in most cases fully developed. Now, it is becoming generally recognised that the contagium of morbilli is conveyed principally by means of the mucous discharges rather than by the air; hence the importance of isolating a

case of morbilli at a period when catarrh is quite incipient; and the only reliable means of doing this which we at present possess is by means of these spots of Filatow's. Of the value of this method of eradicating morbilli from wards I can speak from personal experience, and in the case of schools I would suggest that when at any time it is found necessary to stamp out an epidemic, a daily examination for these spots in the mouths of all the scholars should be carried out in a good window-light, since it is an examination that can be very readily performed, and is the only method at our command which offers any decided hopes of proving effectual.

LAPAROTOMY AND CLEANSING OF THE PERITONEUM IN A CASE OF TUBERCULOUS PERITONITIS.

BY GEORGE WILLIAM DAVIS, M.D., B.S. DURH., L.R.C.P. LOND., M.R.C.S. ENG.

ON Feb. 27th, 1900, I was called to visit a girl, aged seven years, who was too ill to continue her visits to the physician in town to whom she had previously been taken. I was told that she was suffering from "catarrh of the stomach."

The condition of the patient was as follows:—The abdomen was very tympanitic and resonant throughout. No fluid could be discovered. Apparently continuous with the edge of the liver was a mass which appeared to be a solid tumour within the abdomen; it extended in the line of the gall-bladder from the liver edge downwards to one and a half inches below the umbilicus, and then was continued across the abdomen to the opposite ribs at the same level, its margin being marked with four large sinuosities. The mass was smooth, resistant to the touch, and it could be grasped at the lower margin by the fingers, giving an impression of a solid tumourous mass. The skin over it was free and no movement in a vertical direction occurred in respiration. Percussion gave resonance over the whole area which was occupied by the mass. Two enlarged glands could be felt in the left iliac fossa. No signs of disease could be discovered in any other organ. There was occasional vomiting which would occur every third day or so. There was a good deal of flatulence and constipation and the stools were greenish and flocculent; they contained much mucus and were very offensive.

With regard to treatment, as the child's temperature registered nightly from 101° to 102° F. she was kept in bed and her bedroom was kept warmed and freely ventilated; she was given such light foods as bread jelly, yelk of egg, rusks, bread-and-milk, meat broths, meat juice, &c.; passive movements of the limbs with massage were performed daily; and castor oil in frequently repeated small doses was given for the constipation, with an occasional enema. The child improved to a certain extent. Many of her symptoms appeared to mend; she became less irritable and slept rather better, the sickness ceased, and the stools improved in appearance. It was, however, difficult to measure improvement in these matters and the measurable symptom, the temperature, showed a gradual average rise by the end of April. The outline of the tumour showed an advance in size to the extent of half an inch in two months. I therefore advised an exploratory laparotomy. The following was the average temperature for the five months:—March, morning, 97·6°; evening, 100·3°. April, morning, 99·5°; evening, 101·5°. May (operation on the 2nd), morning (?); evening, 99·3°. June, morning, 98·8°; evening, 99·6°. July, morning, 98 8°; evening, 98·9°.

On May 2nd chloroform was administered by Dr. James Crombie, and, assisted by Dr. R. R. Law and by Mr. E. C. Stabb, whose kind offer to be present was gladly accepted, the abdomen was opened in the middle line for three inches immediately below the edge of the hard mass referred to above. Some sero-puriform fluid escaped. Digital exploration through the wound discovered extensive but weak adhesions, which were firmest towards the rim of the pelvis but were easily broken down. The tumour-like mass in the upper abdomen appeared to the fingers as a shield of tissue of an even thickness of three-quarters of an inch; it was smooth and resistant and was closely incorporated with the abdominal wall. The impression conveyed to the touch was that of a fibrous structure and it was doubtless a fibrous areola which had originated in the peritonitic inflammation excited in the neighbourhood of tuberculous nodules which would thus be included by the meshes of the inflammatory tissue. The peritoneum was everywhere studded with nodules and one of these was removed for examination from the serous covering of the ileum. The adhesions having been broken down the peritoneal cavity was thoroughly douched out with two gallons of normal saline solution by means of a Spencer Wells large-bore douching cannula, which was carried down with the finger as a guide into the pelvis and into every part of the abdominal cavity. A careful toilet with sponges on holders terminated the operation, and the wound was brought together in its deeper parts by buried sutures of fine silkworm gut and by ordinary silkworm gut for the skin.

The after progress of the case was quite uneventful. On the evening of the operation the temperature rose to 102·6° and from that time it was slightly subnormal for 10 days, after which it rose to 98·8° or 99·4°, at which it has remained since. The following is the report of the Clinical Research Association on the nodule removed: "This nodule shows groups of grey and caseous tubercles embedded in much young inflammatory tissue on the peritoneum. The giant cells are large and numerous."

Eight months have now elapsed since the operation, during which time every endeavour has been made to improve the condition of the child. Exercises after the manner of Mr. Bernard Roth have been employed daily; during the whole summer the child has lived an open-air existence and other rational measures have been employed, while good nourishing solid food has been given, with as much scalded cream as the child could take. The condition of the patient is such as to make the prognosis very hopeful concerning her ultimate recovery, providing one is given a free hand to interfere surgically as often as indication arises. The physical condition of the abdomen has in these five months become modified. The mass which formerly occupied a continuous area as described is now represented by a margin of the original mass next against the liver edge and by scattered masses mapped over the area previously occupied by the shield-like neoplasm. There are yet glands to be felt in both iliac fossæ, but their much greater size leads me to think, in the absence of temperature, that they are probably ensheathed in fibrous tissue. There is a small tuberculous nodule in the fold of the right buttock which has been present since April and which involves the skin. The general appearance of the child has quite altered. From being somewhat wizened and prematurely wise in face, action, and manner, she has plumped up and has become naturally mischievous and romping as a child should be.

In these cases delays have a dangerous end. There is unquestionably a more pronounced progression in gravity between serous and suppurative peritonitis than between serous pleuritis and empyema. Once the effused fluid has become puriform the prognosis as to recovery from operation must be quite a different matter from that of the same case in the serous stage, for the suppurative peritonitis includes a long history—firm adhesions, encysted pus, limited by anatomical boundaries whose resistance is lessened by the continued inflammatory processes, make up together a posse of difficulties not to be encountered with a light heart. To all surgeons accustomed to perform abdominal sections there can surely be no more disheartening condition than these lacunæ with washleather-like sloughy walls containing stinking acrid pus which in many cases are so numerous and so hidden by more superficial adhesions that the main difficulty lies in being sure that all such encystments have been exposed and cleansed. It appears to me that, given the presence of tuberculous-like masses in the abdomen and a nightly rise of temperature not mitigated by treatment and continuing for an entire month, the time has arrived for an

exploratory laparotomy; and there appears to be no reason why such an operation should not be repeated as often as similar indications arise providing that the general condition of the patient is such as would encourage a good prognosis.

Sidcup.

SELENIUM COMPOUNDS AS FACTORS IN THE RECENT BEER-POISONING EPIDEMIC.

BY F. W. TUNNICLIFFE, M.D., M.R.C.P. LOND.,
PROFESSOR OF MATERIA MEDICA AND PHARMACOLOGY IN KING'S COLLEGE, LONDON;
AND
OTTO ROSENHEIM, PH.D., F.C.S.

ALTHOUGH no doubt we may in the immediate future be in possession of a more copious literature on the most interesting recent beer-poisoning epidemic it cannot be denied that at the present time, thanks to the energy of the various workers in this field, we have at our command a very adequate material upon which to base conclusions and criticisms. Upon reviewing especially Kelynack's and Kirkby's book and Reynolds's paper on this subject we were struck, as probably many others have been, with the apparent incongruity between the doses of arsenic taken and the effects produced. Although in some cases the amount of arsenic found in the beer and actually consumed by the patient is unquestionably sufficient to explain the poisoning, in other instances this is by no means clear.

In trying to explain this anomaly four principal alternatives suggest themselves. The first one obviously is to assume a want of accuracy in the results of the quantitative analyses. We must regard all the methods at present employed for the estimation of those very small quantities of arsenic in complex liquids like beer as only capable of giving approximately accurate results. On the whole, however, the results obtained in this connexion err probably in the direction of the maximum rather than in that of the minimum, and we are inclined, therefore, to disregard error in quantitative analysis as an explanation.

It has been further suggested that the arsenic may be present in some organic (biological) combination formed by the action of certain micro-organisms during fermentation; in support of this the work of Gosio and others has been adduced with regard to the power of certain organisms (especially penicillium brevicaule) to form organic gaseous substances from minute traces of solid arsenic compounds. Apart from the fact that these micro-organisms have never been found to exist in the presence of active yeast, it is very unlikely that their products would remain unnoticed in the finished beer, as it is precisely their characteristic smell which serves for their detection in the more minute quantities.

A third series of explanations are characterised by one common feature—viz., their absolute vagueness. They all assume the presence of poisonous by-products of unknown nature formed by the action of pure or arsenicated sulphuric acid during the manufacture of the brewing sugars or during the fermentation of these sugars. No poisonous substance of this class has, however, been isolated and their existence must be regarded as purely hypothetical.

The fourth explanation, and the one adopted by us, is that some tangible poisonous substance which has up to the present escaped detection and estimation has found its way into the beer along with the arsenic. In searching for such a substance we directed our attention to the possible impurities of sulphuric acid other than, but exerting a physiological action similar to, arsenic. Selenium and thallium at once suggested themselves to us.

It is a known fact that selenium occurs together with arsenic in nearly all pyrites and the sulphuric acids prepared from them.[1] It has also lately been pointed out that the present technical operations for the removal of arsenic do not render the acid selenium free.[2] We were able to convince ourselves that even colourless commercially purified English sulphuric acid still contained selenium and that the dark brown commercial "double rectified oil of vitriol" (D.O.V. or R.O.V.) as sent out by the chemical manufacturer implicated in the recent poisonous cases, and therefore probably identical with that alleged to have been ordered by the sugar manufacturers, gave a very strong selenium (and arsenic) reaction. Upon quantitative estimation this latter acid yielded 0·2 per cent. of selenium or 0·3 per cent. selenious acid. We have up to the present been unable to obtain the ordinary "brown oil of vitriol" (B.O.V.) which was actually used in the manufacture of the sugar and which, according to the published analysis, contained about 1·4 per cent. of arsenious acid. It is obviously to be inferred that the percentage of selenium in this latter acid is raised accordingly.

The chemical properties of selenium and selenious acid render it practically certain that they would pass over together with the arsenic into the sugar manufactured by means of the impure sulphuric acid and thus be present in the corresponding beer.

If we now consider selenium compounds from a pharmacological standpoint we find that they are highly poisonous, and although chemically allied to sulphur compounds are in their physiological behaviour practically identical with arsenic. So similar are the effects produced by these two poisons that according to Kobert[3] the one may be easily mistaken for the other. According to C. Obabrié[4] 0 003 grammes per kilo body weight is lethal for dogs. No cases of selenium poisoning have so far been recorded in man, but the general symptoms in animals are identical with those produced by arsenic.[5]

With regard to the detection of selenium we would draw attention to the following points. It is precipitated along with arsenic in Reinsch's test and may be mistaken for arsenic before sublimation. When not specially looked for it may escape detection in the presence of arsenic even after sublimation.[6] By Gutzeit's or Marsh's test for arsenic it is not shown, being precipitated by the zinc and sulphuric acid. A very sensitive reagent for it in colourless sulphuric acid is codeine, with which it gives, in the cold, a green colour, changing to steel blue at warm bath temperature.

From the above considerations we regard the conclusion justified that selenium compounds have played a definite rôle in the recent beer-poisoning epidemic. Their part, however, is subsidiary to that of arsenic. The presence of selenium in the beer would explain many anomalous cases, amongst which may be numbered those in which the dose of arsenic taken was very small, those in which arsenic could not be found in the excretion, and those also (notably two cases of infants at the breast) in which no arsenic could be found in the milk. In the absence of extensive pharmacological investigation upon the higher animals it is impossible to say to what extent the presence of selenium with the arsenic might modify the symptom complex produced by this latter poison.

The most important conclusion, however, which we would draw from our investigations relates not to the past but to the future. In view of the poisonous action of selenium it is absolutely essential that all sulphuric acids used in the manufacture of food products should not only be arsenic but also selenium free.

[6] If selenium and arsenium are precipitated together upon copper foil as in Reinsch's test and carefully sublimated, in addition to the well-characterised crystals of arsenic, fern- or feather-shaped crystals of selenious acid can be distinguished microscopically and may be identified by various methods.

AN INTRA-PERITONEAL METHOD FOR RADICAL CURE OF INGUINAL HERNIA.

BY T. H. WELLS, M.D. LOND., M.R.C.S. ENG.,
LATE ACTING HOUSE SURGEON TO RADCLIFFE INFIRMARY, OXFORD.

HAVING seen the following operation performed by Mr. Symonds with great ease and celerity and with marked ultimate success, it seemed that a short description of the operation as carried out by him might be interesting and instructive. The danger of opening the peritoneal cavity

has of late years been so reduced that it adds little or nothing to the mortality of an operation, and again, in all the methods of radical cure now practised the sac, having been isolated, is opened to insure its being empty; consequently the abdominal cavity is opened in one case as much as in the other.

Description of operation.—The patient having been prepared and anæsthetised in the usual manner, an incision is made two and a half inches long commencing in the semilunar line and ending over the external abdominal ring. This incision extends in its whole length through skin, superficial fat, fascia, &c., and exposes the external abdominal ring in its lower part. The upper one and a half inches of this incision are now prolonged down through the abdominal muscles, &c., the peritoneum is exposed, and all hæmorrhage having been stopped the peritoneum is opened. A finger is next introduced through the opening into the peritoneal cavity and passed downwards through the internal ring into the hernial sac, which is then thoroughly and carefully explored. There being no adhesions between the sac and the abdominal contents these are steadily and carefully reduced by means of the hand outside and finger inside. Having emptied the sac, the first finger being still inside and used as a director, a pair of volsellum forceps are passed along its palmar surface and the apex of the sac is seized and brought up inverted into the upper part of the wound. Having thus got the inverted sac into the upper wound it is twisted once or twice on itself to obliterate its cavity and stitched carefully to the cut surface of the peritoneum with fine silk or stout catgut and the abdominal cavity thus closed. The pillars of the ring are then brought together with fine silk sutures, taking care not to injure the structures of the cord. The abdominal muscles are next brought together in layers over the upper part of the incision and the edges of the skin are brought together with continuous or interrupted sutures of silkworm gut.

To recapitulate, the operation may be divided into seven stages: (1) an incision two and a half inches long in the linea semilunaris, ending over the external abdominal ring and passing through skin, fat, and superficial and deep fascia; (2) deepen the upper one and a half inches through the abdominal muscles, transversalis fascia, and subperitoneal fat, and having arrested all hæmorrhage open the peritoneal cavity; (3) explore the sac with the finger and remove any gut; (4) insert forceps along the palmar surface of the finger, seize the apex of the sac and invert it, bringing it out into the upper wound; (5) stitch the sac, after giving it a couple of twists on itself to obliterate its cavity, to the peritoneum; (6) stitch up the external abdominal ring; and (7) close the wound by bringing the structures layer by layer into accurate apposition.

The advantages claimed for this operation by Mr. Symonds are as follows. Firstly, it is expeditious. The most tedious part of a radical cure is often the finding of the sac, its subsequent separation from the structure of the cord, resulting in many cases in considerable manipulation and frequently laceration of the walls and contents of the inguinal canal and scrotum—by this method the sac is found immediately. It might be argued that there would be considerable difficulty in seizing and inverting the sac, but such is found not to be the case, and if it should occur one still has the advantage of immediately defining and exploring the sac before proceeding further. The following case is an illustration of this point. A well-built labourer, aged 36 years, was admitted to the Radcliffe Infirmary for right inguinal hernia. 12 months previously he had been operated upon for the same thing, but three days after the operation he developed pneumonia and was very ill for three weeks with continuous cough. Owing to cough and straining the wound had given way and he had since been obliged to wear a truss. In this case Mr. Symonds decided to operate by the intraperitoneal method, though owing to previous operation and having worn a truss he anticipated some difficulty in inverting the sac. On exploration omentum was adherent to the sac, but it inverted readily and the omentum was stripped off in the upper wound where any bleeding could be easily seen and arrested. Secondly, the neck of the sac is obliterated high up. Thirdly, the inverted sac aids in forming a firm scar. Fourthly, the sac and contents can be explored and if necessary the sac opened below quickly and safely. Fifthly, the incision allows any methods of closing the inguinal canal and external ring to be carried out which the operator may desire.

Banbury, Oxon.

A CASE OF PRIMARY CARCINOMA OF THE VERMIFORM APPENDIX.

WITH REMARKS.

BY T. R. C. WHIPHAM, M.B. OXON., M.R.C.P. LOND.,
MEDICAL REGISTRAR TO ST. GEORGE'S HOSPITAL.

THE patient, a female, aged 45 years, was admitted into St. George's Hospital on Sept. 11th, 1900, under the care of Mr. G. R. Turner, with great swelling of the abdomen and a tumour in the left iliac region which was diagnosed as carcinoma. Surgical interference being deemed impracticable she was transferred to the care of Dr. F. G. Penrose, to whom I am much indebted for permission to publish the case. There was nothing noteworthy in the patient's history and she had always enjoyed good health until five or six weeks previously to her admission. From that time, however, she had been rapidly losing flesh and strength, and for the last fortnight had noticed that "the stomach was swelling" and that she had passed very small quantities of urine. Defecation was normal and regular. Her condition on admission to the hospital was one of marked emaciation and her complexion had a malignant sallow tinge. The abdomen was much distended and tender, the skin being white and shiny, with œdema present over the lower part. The superficial veins on the abdomen and lateral aspects of the chest were enlarged. In the left iliac fossa and the adjoining part of the hypogastrium was a large, hard, irregular mass of about the size of two fists and arising apparently in the pelvis. There were dulness in the flanks, though unaltered by position, and a marked thrill as of free fluid in the peritoneal cavity. The liver was not apparently enlarged. The legs were slightly œdematous. Per rectum a large mass was felt in Douglas's pouch, but a vaginal examination by Dr. A. F. Stabb failed to throw any further light on the case. No enlarged glands were felt. The urine was normal and the temperature was not raised. The course of the case was one of steady decline accompanied by occasional attacks of vomiting. The patient was kept under morphia for the relief of the pain and she died on Oct. 3rd.

At the necropsy the abdomen was found to be greatly distended by a large quantity of serous effusion. The peritoneum over both the parietes and viscera was densely studded with innumerable nodules of growth, a large number being on the abdominal surface of the diaphragm. The intestines were matted together, the omentum was thickened and infiltrated, and the mesenteric glands were enlarged.

FIG. 1.

Vermiform appendix in transverse section, actual size, showing great thickening of the intima. M, Mesentery.

Throughout its entire length the mucous membrane of the alimentary canal was intact, with the exception of a small portion at the origin of the vermiform appendix which was occupied by new growth. One or two secondary deposits of the size of peas were found in the liver, and the left ovary was transformed into a mass of growth measuring about six by four inches, the surface of which was irregular and presented some minute cysts. In the right ovary was a unilocular cyst of the size of a cricket-ball. The other viscera showed no signs of new growth. The lymphatic glands in the neck, in the anterior mediastinum, and in the groins were hard and enlarged.

The above case, in which I performed the necropsy, is

interesting on account of the rarity of cases recorded in which the appendix has been the seat of a primary carcinomatous invasion. That this was the case in the present instance there is apparently but little doubt. To the naked eye cross section of the appendix showed a notable increase in the thickness of the inner coats with but comparatively slight involvement of the muscular layers, and none of the peritoneal, points which are well brought out in the accompanying drawings of a transverse section (Fig. 1 and Fig. 2.). The mucous membrane is seen to be extensively involved by spheroidal-celled carcinoma, some of the gland tubes showing early proliferation of their cells, while the muscular coats are invaded to a much less degree. That this was the only part of the intestinal tract involved points strongly to its being the original focus of the disease, and the cancerous condition of the left ovary may be considered as due to dissemination, that organ being liable to infection in cases of abdominal carcinoma. To Dr. H. D. Rolleston my thanks are due for the expression of his opinion on the microscopical evidence which is in accord with this view. It is further remarkable that Dr. Rolleston himself recorded a case of primary carcinoma of the appendix [1] which occurred at St. George's Hospital as recently as in March last, though from a clinical point of view these two cases afford a marked contrast. In neither, it is true, was cancer of the appendix suspected. Dr. Rolleston's case was apparently one of ordinary relapsing appendicitis, whereas the present case ran a course which is usually associated with malignant disease and presented no symptoms of the appendix being involved.

It has been stated that primary carcinoma of the vermiform appendix is perhaps not quite so rare an affection as has been commonly supposed, and certainly the occurrence of these two cases at St. George's Hospital within a period of seven months would favour that view. The reasons why cancer of the appendix is overlooked are: (1) that appendices after removal are not submitted to microscopical examination as a routine practice; and (2) that in dissemination of the disease the appendix may be involved in a large mass of growth implicating the cæcum or other parts which may be thought to have been the origin of the affection. In Dr. Rolleston's case it may be noted that the appendix was examined more or less by chance, and in the present case it was fortunately lying comparatively free.

The literature of the subject up to the date of his case is fully set forth by Dr. Rolleston in the article above referred to, but he has kindly drawn my attention to the fact that since then Elizabeth Hurdon [2] has recorded a case of primary spheroidal-celled carcinoma of the appendix in a woman, aged 24 years, who was thought to have a floating kidney. The appendix after removal was found to have a small oval swelling projecting into its lumen so as practically to obliterate it. On further examination it proved to be carcinoma. Kelly [3] has collected from literature 18 cases of primary cancer of the appendix, and to this number he adds two of his own which were both of the spheroidal-celled variety. He also describes an endothelioma and refers to the previously published cases of an endothelial sarcoma by Glazebrook and of a psammoma by Kanthack and Lockwood. Innocent tumours of the vermiform appendix, according to the same observer, appear to be even rarer than are those of primary malignant disease, and he has only met with two cases of fibro-myoma of the appendix, both of which were associated with similar growths in the uterus. As evidence of the large amount of work that has been done in this direction it may be noted that during the years 1897–1899 Kelly examined 706 appendices removed by Deaver at the German Hospital, Philadelphia, while Maydl and Nothnagel have analysed altogether 41,838 necropsies performed in

FIG. 2.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF DIPHTHERITIC PARALYSIS.

BY A. J. RICE OXLEY, M.B. DUB.

THE following notes of a case of diphtheritic paralysis after very slight sore-throat are so interesting and emphasise so clearly some of the points referred to by Dr. E. F. Trevelyan in his able paper[1] that I venture to think they may be worth recording.

A boy, aged 10½ years, was brought to me some little time ago by his father who stated that the boy could not swallow properly, fluids returning through his nose, and that there was something in the throat or nose causing this state of things. He wished to know if an operation was necessary for the removal of the obstruction. Two medical men had seen the boy and one of these said he had found the growth and was very anxious to have the boy anæsthetised and operated on without delay. I elicited the fact that the boy's sight was also so much interfered with that he was frequently reprimanded at school for inattention when in reality he was unable properly to distinguish figures and writing on the blackboard. The character of his voice and the history that he had been at home for two days with slight sore-throat made me suspicious and on examination the palate was found to be practically motionless. Except for this and the affection of vision there were no other very marked symptoms of any kind. The boy, as I have stated, had returned to school and but for the regurgitation of fluids through his nose would probably have continued at school. Some of the home circle were inclined to look upon the nasal regurgitation as a bad habit or trick, the boy's general condition was so good and the sore-throat had attracted so little attention. Removal from school and a course of the usual tonics cured the paralysis and the impaired vision.

Streatham.

A FOREIGN BODY IN THE ARM FOR 10½ YEARS.

BY A. R. HENCHLEY, L.R.C.P., L.R.C.S. EDIN., L.F.P.S. GLASG.

ACCOUNTS are so often given in the columns of the medical press of cases where foreign bodies have migrated from the position of entrance to some more or less remote part of the body that the present case seems worth mentioning. In this case the foreign body remained practically in the same position as it entered notwithstanding the great lapse of time and its being situated in the arm.

On Dec. 26th last a young man, working as a labourer, came to me saying that he thought he had a piece of glass in his arm that he wished removed. He said that 10½ years ago while "playing at horses" with some boys he stumbled and fell on some broken glass. His left arm bled freely, but healed up all right in due time and gave no further trouble till a few days before, when a friend happened to pinch him just over the place and he felt a sharp pricking pain. On examination of the arm I found a stellate-shaped scar about three inches above, and slightly external to, the internal condyle of the humerus, and one and a half inches internal to and on the same level as the scar was to be felt a fairly moveable oblong body about two inches in length. After having made the skin aseptic I sprayed it with ether and made a vertical incision three-quarters of an inch long, and eventually got out a piece of glass a quarter of an inch thick and about one and a half inches long and the shape of an old-fashioned *f*. It was imbedded in a considerable amount of tissue.

Blagdon, Bristol.

A PECULIAR COMPLICATION IN MIDWIFERY.

BY JAMES MORE, M.D. EDIN.

SOME little time since I was called in by a midwife to see a patient of hers who had been in strong labour all day without any appearance of its coming to a satisfactory termination. The midwife informed me that there was something unusual in the case as she could not make out the presentation. On examination I was myself quite at a loss as to its nature. I found the lower outlet of the passages completely blocked up by some part of the child but what that part was I could not make out. It seemed like a spongy mass with one opening in the centre, into which the finger could be easily introduced. It was not the mouth as the jaw was absent, nor the anus as the pelvic bones were not within reach. I determined to introduce my hand and explore, and on doing so I was surprised to find that the mass was indeed the breech with the fœtal vagina much swollen and congested. On delivering I found this part of the child very much swollen and almost black, evidently caused by the nurse poking her finger into the opening under the idea that it was the os uteri—a mistake I could quite understand under the circumstances and which I was on the verge of committing myself.

ST. MARY'S HOSPITAL.

TIGHT BANDAGING; ISCHÆMIC PARALYSIS IN AN ADULT.[1]

(Under the care of Mr. EDMUND OWEN.)

THE paralysis following the application of a splint has been termed "ischæmic paralysis," on the supposition that the pressure on the vessels of the limb has impaired the blood-supply of the part so that the muscles have suffered and perhaps a chronic inflammation with sclerosis of the muscles has followed. Mr. H. Littlewood attributes it[2] merely to contraction of the muscle in healing after being torn. It is, however, not improbable that another factor is concerned in the production of this variety of paralysis, and this other factor is a neuritis of the motor nerves of the part resulting from the excessive pressure of the splint. In some cases one of these factors, in other cases the other, may be the chief or only cause of the palsy, but it is not improbable that in most instances both causes act.

A man, 30 years of age, a carpenter, was admitted into St. Mary's Hospital on March 31st, 1900. 17 months previously, when working on a wall at Krugersdorp, in the Transvaal, he fell about 15 feet, and stretching out his left hand to save himself, he "broke the outer bone" of his forearm a few inches from the wrist. (The fracture duly consolidated.) He was treated by a Scotch practitioner and a Boer practitioner in consultation, who fixed the arm between an anterior and a posterior splint which reached from the bend of the elbow to the wrist. The patient said that the splints were bound on very tightly by three pieces of bandage which were put on through looped ends—"bowlines"—and hauled taut. He said that he complained at the time that the splints were too firmly bound on, but that no notice was taken of his complaint; so he thought that such harsh treatment

[1] Reported at a meeting of the Medical Society of London on Jan. 28th, 1901, and the case exhibited.

[2] THE LANCET, Feb. 3rd, 1900.

was probably in accordance with the needs of the injury. In four days' time—during which he had suffered intense distress—the splints were taken off, the hand being much swollen; they were afterwards re-applied. The splints were removed from time to time and gentle massage was done during 30 days, after which the splints were entirely left off. The hand, however, remained swollen for at least two months, and during this time he lost the nails of his first and second fingers. The thumb-nail also blackened, but it did not come off. When the swelling went down there was very little feeling in his hand, and his fingers and thumb were stiff and useless. About a fortnight after the accident two sloughs appeared—an extensive one over the outer side of the forearm near the elbow and a deep one over the tuberosity of the scaphoid bone. The resulting sores took respectively three and four months to heal.

The forearm was found to be fixed midway between pronation and supination; the thumb was strongly adducted with the terminal phalanx rigidly flexed, and the fingers were stiffly bent into the palm. On firmly flexing the wrist the fingers could be partly straightened, but the thumb was immoveable and the hypothenar muscles were much wasted. Faradaism gave no reaction, but galvanism set up sluggish contractions. There was considerable anæsthesia in the hand and fingers. The outlook was most unpromising, but the man readily accepted the suggestion that an attempt should be made to put slack into the pronator radii teres and most of the flexors by taking an inch out of the upper part of the radius and ulna. After this it was found that he could get his fingers straighter and had much more power of rotation of the forearm; but the improvement was not marked, so most of the tendons at the front of the wrist were exposed by operation, split, cut, lengthened, and sutured.

In October the man was re-admitted because non-union had followed the operation on the bones, and as the tendons seemed to need more slack being put into them, another inch was removed from the bones by the electric saw, and the fresh ends were adjusted by wire sutures. An operation was done for lengthening the long flexor tendon of the thumb. The limb was adjusted in a plaster-of-Paris apparatus as before, the wound healed perfectly well, but, as before, there was no solid union and the question is, "Can anything more be tried for him?"

Remarks by Mr. OWEN.—The pathology of the case is probably this, that the tight and long-continued compression of the forearm kept the muscles completely starved of blood, and so injured them that a myositis supervened, which, in its turn, was followed by an intractable fibroid degeneration of the tissue with permanent contracture. It was Volkmann who first described the disease and found the name for it, *ischæmic* (ἰσχω, restrain; αἷμα, blood) *paralysis*.

I have seen a good many cases of ischæmic paralysis in children, but I have never previously met with an instance in an adult; and I should not be surprised to learn that no other case in an adult has been recorded, for an adult, as a rule, would absolutely decline to submit to the agony of the tight compression. In children the myositis has sometimes been determined by a few hours' compression, and, of course, the tighter the compression the shorter need be the period. My own experience of operation in these cases has been most unfavourable, but my colleague, Mr. Herbert Page, was enabled to speak more hopefully in a case which he recorded in a valuable clinical lecture in THE LANCET of Jan. 13th, 1900, p. 83.

PARK HOSPITAL, HITHER GREEN, S.E.

A CASE OF ENTERIC FEVER; LARYNGEAL PERICHONDRITIS, TRACHEOTOMY; RELAPSE, PERFORATION, LAPAROTOMY; NECROPSY.

(Under the care of Dr. A. KNYVETT GORDON, Senior Assistant Medical Officer.)

THE value of absence of liver-dulness as an indication of free gas in the peritoneal cavity is not so great as was at one time thought, but the sudden appearance of this sign during the course of typhoid fever is necessarily of great importance and is very suggestive of perforation. The mortality after laparotomy for perforation in typhoid fever must always be high, for the patient's general condition before the perforation occurs is usually very bad, and the added shock of the perforation and of the operation is sufficient frequently to prove fatal even if no marked peritonitis should have followed. Mr. J. E. Platt has collected 103 cases, and in 21 of these the patients recovered.[1] This is a mortality of nearly 80 per cent.

A well-nourished boy, aged 15 years, was admitted to the Park Hospital on Sept. 20th, 1900, suffering from an attack of enteric fever which was stated to have begun on the 16th. On admission he was found to be moderately ill: there were slight abdominal distension and enlargement of the splenic dulness, nocturnal delirium, headache, and slight diarrhœa. The temperature was 39·8° C., the respirations were 25, and the pulse was 110. The mouth was very dirty, the tongue and gums being covered with dried muco-purulent secretion; there was one carious molar tooth discharging pus which was extracted on admission. He became worse and his attack ran a severe course which, however, with the exception of hæmorrhage from the bowel on Sept. 28th, 29th, and 30th, did not present any special features until the morning of Oct. 15th. On that day the respiration became stridulous and he rapidly developed symptoms of laryngeal obstruction; there were great distress and rapidly increasing cyanosis with very slight epigastric recession. In the afternoon, about 10 hours after the onset of the stridor, a high tracheotomy was performed after injection of eucaine subcutaneously, no general anæsthetic being required. A No. 5 Parker's tube was inserted, with complete relief of the symptoms. On the next day it was possible to see the larynx with difficulty and a large swelling was found over the right arytenoid cartilage and ary-epiglottic fold; it was bright red in colour and was causing almost complete glottic obstruction. On Nov. 2nd he was able to breathe without the tube for a short time, and the metal tube was replaced by a rubber one which he wore for gradually decreasing periods until his death, but his voice did not return at all. As seen with the laryngoscope the swelling appeared to be lessening gradually; there was no sudden discharge of pus but the sputum was muco-purulent throughout. The temperature, which had been raised at first daily to 40° C. but had been controlled easily by tepid sponging, began to fall on Oct. 10th and reached normal on the 15th, the pyrexia having thus lasted 28 days. On Oct. 28th the temperature rose again and a relapse occurred, the second attack being considerably milder than the first and presenting no features of interest until the afternoon of Nov. 10th, when he vomited slightly, but was not otherwise worse. On the 11th, at 10 A.M., he became suddenly worse, the chief symptom being rapidity of breathing; there was no abdominal pain at all and the temperature, which ranged from 38° to 39° C., did not fall; there was no marked collapse, vomiting, or hiccough. On examining the abdomen there was greatly increased distension, and the liver dulness, which had been normal at noon on the preceding day, had completely disappeared; the abdomen moved very slightly, and the diaphragm was acting; a long tube was passed per rectum as far as the sigmoid flexure, but no gas escaped.

It was thought that perforation had occurred, and as the boy, though much emaciated by his long illness, was not moribund it was decided to open the abdomen. This was done at 3.30 P.M.—probably six hours after perforation—through an incision in the right linea semilunaris, chloroform being administered through the tracheotomy tube. In the incision, which was four and a half inches long, the deep epigastric artery was cut and was ligatured, bleeding being completely arrested. On opening the peritoneum fœtid gas escaped and a quantity of clear serous fluid welled up, but there was no sign of pus; a coil of small intestine presented which was brightly injected on its surface. The appendix was felt, and on tracing the ileum back a perforation was found, from which fæces were escaping, four and a half inches from the ileo-cæcal valve and about three inches from the presenting coil. This perforation was of the size of a crowquill and was situated in an ulcer one and a half inches long and three-quarters of an inch wide. Lembert's sutures of fine silk were now passed so as to invaginate the entire ulcer and the intestine a quarter of an inch on each side, the stitches reaching to half an inch from each end of the visibly ulcerated surface. As the boy's condition did not admit of a prolonged peritoneal toilette the fluid was sponged out as gently as possible and the abdomen was sewn up with silk-worm gut, a gauze drain being left at the lower angle of the wound. The whole operation lasted an hour and 20 minutes

[1] THE LANCET, Feb. 25th, 1899, p. 505.

and the boy at its conclusion, though very feeble, was warm, and there was a fair radial pulse. He rallied from the anæsthetic and was doing well until four hours after the operation, when he vomited some bilious fluid; this was followed by sudden collapse and some blood was noticed in the dressings. He died almost immediately.

Necropsy.—At the post-mortem examination, which was made 24 hours after death, about two ounces of blood-clot were found in the right side of the abdomen and there was a clot of the size of a hen's egg in the abdominal wall at the lower angle of the wound. On dissection the end of the deep epigastric artery was found from which the ligature had slipped. The perforation which had been sewn up was found to be watertight; there were several ulcers from which the sloughs had separated in the lower end of the ileum, and three higher up with the sloughs *in situ*. There was no other perforation and there was no other ulcer which appeared to be likely to have perforated subsequently. The tracheotomy wound was through the first two rings of the trachea in the middle line; the right arytenoid cartilage was represented by a few fragments in an abscess cavity which involved the right ary-epiglottic fold and also extended across the middle line posteriorly to the left arytenoid region for a space of a quarter of an inch. The whole cavity would have held about two drachms of pus, though it was quite empty at the necropsy. There was no sign of ulceration in the rest of the larynx.

Remarks by Dr. GORDON.—The points of interest in this case are many. Perichondritis laryngis is rare if attention is paid to the condition of the mouth; this, which I regard as a most important point in the treatment of enteric fever, consists in extracting all carious teeth on admission and in subsequently having the mouth swabbed and the teeth brushed with a solution of peroxide of hydrogen and bicarbonate of soda. When perichondritis does occur it almost always suppurates. In this case the suddenness of the onset is remarkable; to open the abscess intra-laryngeally would have been impossible without a preliminary tracheotomy, the distress was too great; afterwards the abscess burst of its own accord.

With regard to the abdominal condition the diagnosis of perforation was able to be made early—certainly in the first 12 hours—owing to the very marked disappearance of the liver dulness; and it is interesting that the perhaps too classical signs—collapse, abdominal pain, and sudden fall of temperature—were all absent. It was fortunate that the perforated ulcer presented itself almost immediately, so that no prolonged exploration, with its attendant risk of causing additional perforation, was necessary.

It is, I take it, uncertain whether cases of perforation ever recover without operation, though I believe that such recoveries are more probably cases of peritonitis, apart from perforation of sudden onset. If a diagnosis can be made in the first 24 hours, and the patient is not obviously moribund, I believe that it is best to open the abdomen in the right linea semilunaris at once; if, on opening the peritoneum, there is no escape of gas or evidence of peritonitis the incision can be at once closed, but if a perforation can be found without prolonged exploration, and sewn up, the chances of recovery are better with the operation than with rest and opium alone.

The immediate cause of death in this case was, I believe, the slipping of the ligature in the motion of the abdominal wall caused by the vomiting. It is impossible to say whether, after six weeks' acute illness, the patient would have otherwise recovered, but at all events one more case is added to those in which the condition on opening the abdomen was found to be a surgically hopeful one.

For permission to publish this case I am indebted to the courtesy of Dr. R. A. Birdwood, medical superintendent of the hospital.

NORTH LONSDALE HOSPITAL, BARROW-IN-FURNESS.

A CASE OF FRACTURE OF THE PELVIS WITH INJURY TO THE BLADDER AND PELVIC VESSELS.

(Under the care of Mr. P. L. BOOTH.)

THE close apposition of the urethra and bladder to the pubic bones, and the frequency with which the rami of these bones suffer in fracture of the pelvis by a compressing force, serve to explain the injury of one or both of these organs so commonly met with. The hydrostatic test of the soundness of the bladder is usually considered to be fairly trustworthy, but it can certainly not be relied on for minute or valvular punctures as in the case recorded below. The injection of a few cubic inches of air seems to be more useful, for the free gas in the peritoneum is readily recognisable, but Mr. Walsham has recorded one case[1] in which profound collapse occurred immediately after the injection. In all cases extra-peritoneal rupture of the bladder is more difficult to recognise than the intra-peritoneal form. For the notes of the case we are indebted to Dr. H. H. Broome, house surgeon.

A man, aged 36 years, was assisting to unload a cart full of clay when suddenly a large mass, weighing several hundredweights, fell and struck him in the back. He was stooping at the time and the force of the blow knocked him forwards on to his abdomen, where he remained for several minutes buried, with the exception of his head and legs, beneath the mass. He was dug out and taken to the North Lonsdale Hospital, Barrow-in-Furness, where he was admitted as an in-patient at 5 P.M. on Dec. 10th, 1900.

On admission the patient was in a condition of extreme collapse with a feeble running pulse. He complained of pain in the right and left loins, and shortly after being placed in bed he voluntarily passed seven ounces of almost pure blood. He stated that he urinated about one hour before the accident.

On examination it was found that there was great tenderness in the right and left loins and also in the right groin. There was pain on pressing on the anterior superior iliac spines and also on pressing on the pubic symphysis, but no crepitus was elicited and no irregularity in the outline of the ischio-pubic arch or horizontal ramus could be made out. There was no injury to the spinal column or cord. A catheter passed easily into the bladder and two ounces of blood mixed with urine were drawn off. No irregularity could be felt in the wall of the bladder and the point of the instrument could not be made out through the anterior abdominal wall. The bladder was then distended with 14 ounces of boric solution and rose above the symphysis, giving rise on percussion to a corresponding dull area in the hypogastrium. On withdrawing the fluid exactly the same amount as was injected (14 ounces) was obtained and the dull area disappeared. There was no evidence of free fluid in the abdominal cavity. It was thought probable that one or both kidneys were injured, but as the collapse was so great it was decided not to explore. Ice-bags were applied to the loins and ergot was administered hypodermically every four hours.

On the morning of Dec. 11th the patient was still collapsed, with cold extremities and profuse clammy perspiration. The temperature was 100·1° F., the pulse was 140, and the respirations were 25 to the minute. There was tenderness to pressure in the hypogastrium and swelling and fulness were present in both loins. The patient was much troubled with retching but there was no actual vomiting. On catheterisation one ounce of bloody urine was withdrawn. In the afternoon at 3 o'clock he voluntarily passed one ounce of bloody urine and at night another ounce was withdrawn by the catheter. During the whole course of the day only three ounces of urine mixed with blood were obtained from the bladder. On the morning of the 12th the patient was profoundly collapsed; the pulse was 172, the temperature was 101·6°, and the respirations were 40. The extremities were cold, numb, and cyanosed. Death occurred at 10 50 A.M.

Necropsy.—At the post-mortem examination both horizontal rami of the pubic bones were found to be fractured at a distance of three-quarters of an inch from their junction with the body on either side. There was no displacement of the broken ends, as the ischio-pubic arch was intact, but several fragments were detached from the pelvic surface of the ramus, and on the right side two of these had penetrated the extra-peritoneal surface of the bladder, passing through the walls in an oblique direction. The space between the inferior surface of the bladder and the posterior surface of the symphysis was filled with a mass of blood-clot which passed backwards around the neck of the bladder to the posterior wall of the pelvis and thence extended upwards, behind the peritoneum on the posterior abdominal wall, as high as the posterior surface of the liver. This large clot passed up along the sides of the rectum, extended for

[1] The Transactions of the Royal Medical and Chirurgical Society, 1895.

some distance between the layers of the sigmoid mesocolon, completely surrounded both kidneys, and separated the layers of the mesentery of the small intestine for one or two inches. The bladder was small, firm, and contracted, and on passing the finger into it two spicules of bone could be felt projecting through the inferior wall. Both kidneys were absolutely uninjured though buried in clot which completely filled up the hilum extending even between the calices of the pelvis. The spleen and the rest of the abdominal viscera were free from injury, as also were the abdominal aorta and its main branches. It was impossible to make out the vessels from which this large amount of blood had escaped, but it seems probable that the fracture of the horizontal rami had caused rupture of the obturator vessels, the blood first filling the pelvis and then ascending beneath the peritoneum on the posterior abdominal wall.

Remarks by Dr. BROOME.—The above case may prove of interest from the difficulty of diagnosing the injury to the bladder. This was due to the nature of the injury, the inferior extra-peritoneal surface being obliquely perforated by two spicules of bone in such a manner as to render the apertures valvular so that they became tightly closed when the viscus was distended.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

Ischæmic Contracture.—Typhoid Fever.

A MEETING of this society was held on Jan. 28th, Mr. J. H. MORGAN, the President, being in the chair.

The CHAIRMAN referred to the irreparable loss that the nation had sustained since the last meeting of the society and proposed that the humble expression of the profound grief of the Council and Fellows and their extreme admiration of the many virtues of Her late Majesty should be forwarded through the proper channels and joined with an expression of their deepest sympathy to His Gracious Majesty King Edward VII.

Mr. EDMUND OWEN showed a man who, when living in the Transvaal, had sustained a Fracture of One of the Bones of the Left Forearm. He had been treated by splints and bandages. The latter were bound tightly and caused sloughing of the skin and loss of the nails. This was followed by the condition described by Volkmann as ischæmic myositis. In order to remedy the fixed flexion of the fingers and thumb Mr. Owen elongated the tendons and excised one inch of both bones of the forearm. The bones failed to reunite. Later he removed an additional portion of each bone and wired the ends together. In spite of every care non-union again resulted and the patient still had an almost useless hand. An account of the case is given in our "Mirror of Hospital Practice" this week.—Mr. F. C. WALLIS had experience of a similar case where the condition was attributable to an Esmarch's band having been used for one and a half hours during an operation.—Dr. WILLIAM HUNTER thought that the trophic disturbance probably began in the nerves rather than in the muscles.—The PRESIDENT referred to a case in which the ulnar nerve had been divided by a bullet in the present war. The patient, invalided home, was treated by freshening the ends and grafting in a portion of the sciatic nerve of a freshly-killed sheep. A return of nearly normal sensation had resulted and muscular power was beginning to return.—Mr. OWEN, in reply, said that in cases like the one which he had brought forward there was no localised nerve-lesion, so that from a practical point of view after milder measures had failed the only hope was in treating the effects of the fibrosis and shrinking of muscles.

Dr. F. J. SMITH then read a paper on the Treatment of Typhoid Fever which is printed *in extenso* on p. 312 of this issue.—Dr. SIDNEY PHILLIPS agreed that no routine treatment applied to all cases of typhoid fever. He was the first in this country to bring forward fatal cases of typhoid fever in which necropsies had shown that there had been no appreciable intestinal lesion. The stress of the disease might fall chiefly on the central nervous organs, the lungs, or the kidneys. Marked tremor, as Jenner had taught, was frequently associated with deep intestinal lesions, but it might also result independently from toxæmia or pyrexia. As to the dietary he would be guided rather by the patient's power of digestion than by the appetite. He had not found it necessary to cut down the amount of milk to two or three pints; if the condition of the digestion allowed, as much as five or six pints could be given. He doubted the propriety of giving solid food. For hæmorrhage he had in some cases given tincture of hamamelis with advantage; for this complication opium remained the chief resource, but its effects should be watched so that it did not produce tympanites. He had noticed that dilatation of the stomach was sometimes mistaken for tympanites. The latter was of grave augury and he attributed it to severe toxæmia. He agreed with Dr. Smith that the ambulant cases were the worst.—Dr. G. WASHINGTON ISAAC had been disappointed with the results of tepid sponging as a means of keeping down pyrexia.—Dr. CAMPBELL POPE suggested a trial of suprarenal extract in case of hæmorrhage.—Dr. WILLIAM HUNTER thought it impossible to gauge the extent of the intestinal ulceration, and it was therefore impossible to make this a criterion for choice of diet. The dangerous ulcers were due, he thought, to ordinary septic as distinguished from typhoid inflammation. Hence he agreed with Dr. Smith in valuing antiseptic treatment, and to this end he preferred calomel or perchloride to salol and other artificial antiseptics.—Dr. W. J. HADLEY thought that pulmonary lesions caused a fatal issue more frequently than intestinal complications. Heart failure was usually the result of toxæmia and pyrexia.—Dr. SMITH, in reply, said that he doubted whether solid food caused perforation. For pyrexia he had employed a bath at 100° F. with good results. The patient might remain in it as long as he liked. Constipation often kept up pyrexia and sulphate of soda he found to be the most generally useful remedy for this.

CLINICAL SOCIETY OF LONDON.

Exhibition of Patients and Apparatus.

A MEETING of this society was held on Jan. 25th, Mr. A. PEARCE GOULD, Vice-President, being in the chair.

The CHAIRMAN explained that the President, Sir R. Douglas Powell, who had discharged such important duties during the last illness of their late Sovereign, did not feel able to be present at the meeting. As this meeting was of a purely scientific character it had been decided to hold it. He felt, however, that the society could not meet without some expression of the personal loss which the members shared with the whole empire. The greatest monarch of modern times had been taken from them. During her reign great advances had been made in scientific medicine. The late Queen had always placed implicit confidence in her medical advisers. She was the first member of our Royal Family to be vaccinated. When prejudice was against the boon of anæsthesia being afforded to women in the hour of their greatest need she had availed herself of it and so removed the prejudice. To antiseptic surgery she had set her seal by granting to Lister the highest honour ever given to a medical man in this country. When the country was threatened with an epidemic of cholera Her late Majesty had taken the greatest interest in the measures successfully adopted against it under the guidance of the late Sir R. Thorne Thorne. He was sure that to these reflections all would add with devout feeling, "God save the King."

Mr. STANLEY BOYD showed a female patient, aged 31 years, on whom he had performed Oöphorectomy for Recurrent Mammary Cancer. In 1898 the left breast was removed for cancer. In 1900 operation for recurrence was contemplated and abandoned. In August, 1900, the patient was emaciated; there were recurrence in the scar, two outlying subcutaneous nodules, considerable enlargement of the left supra-clavicular and substerno-mastoid glands, the latter rather fixed. many large hard glands in the right axilla and a few in the right neck. The left vocal cord was paralysed and the patient had great difficulty in swallowing fluids. On August 8th Mr. Boyd performed double oöphorectomy. Improvement was rapid from the day of operation. On Sept. 8th the nodules and glands except one beneath the sterno-mastoid had disappeared. On Dec. 4th the voice and swallowing were normal. The patient had gained one and a half stones in weight.—Mr. CHARTERS SYMONDS remembered

the patient being under his care. Her condition then appeared to be hopeless and he fully confirmed Mr. Boyd's account of her improvement.—Mr. GEORGE EASTES asked whether Mr. Boyd would recommend the operation after the climacteric.—Mr. MCADAM ECCLES asked whether the ovaries were examined microscopically.—Mr. A. E. BARKER asked how much of the broad ligaments were removed with the ovaries.—Mr. BOYD, in reply, said that though after the climacteric the chances of success were less, still in otherwise hopeless cases the operation was justifiable. The ovaries were not examined histologically, but save for some simple cysts in one they had all appeared to be normal macroscopically. He had removed some of the tube with each ovary but had not made a point of getting close up to the uterus.

Mr. BRUCE CLARKE showed a case of Intractable Ulcer of the Forearm. The patient was a female, aged 20 years, who had had a lump on the back of the right forearm since she was 10 years old. In July, 1898, she fell and an ulcer formed. Since Oct. 6th, 1898, all kinds of local and general treatment had been tried, but the ulcer had gradually extended. In August, 1900, parts of the ulcer assumed a fungating character as of an epithelioma starting. Later glands in the axilla enlarged and were removed. The microscope gave negative results.—Mr. CHARTERS SYMONDS remembered a similar instance in the foot of a young woman in which recurrence took place after amputation of the foot. Amputation was done in the upper part of the leg and after that the patient remained well.—Mr. BRUCE CLARKE replied that before adopting extreme measures he would give a little longer time to see what could be done by good nursing.

Dr. H. D. ROLLESTON and Mr. S. VERE PEARSON showed a case of Generalised Scleroderma with Raynaud's Disease. The patient was a single woman, aged 22 years, who began to suffer from a combination of scleroderma and Raynaud's disease, which appeared to have come on simultaneously six and a half years ago. The left ear had recently become slightly affected. There was a family history of phthisis but no evidence of hereditary or acquired syphilis. There was scleroderma of the whole of the face. The skin was shiny and so stiff that the eyes could not be completely closed or the jaws sufficiently opened to allow the extraction of decayed teeth. The forearms to the lower parts of the arms were affected by scleroderma, which was advancing, and supination and pronation of the arms were interfered with. There was slight scleroderma on both infra-mammary regions and on the right back and flank. Changes caused by Raynaud's disease were present in both fingers and toes.

Dr. RISIEN RUSSELL showed a case of Myasthenia Gravis. The patient was a male, aged 57 years, who had good health until 11 months ago, when "blood-poisoning" from a septic condition of the right index finger took place. The finger was amputated. He had not been strong since and his legs and right hand used to swell during the first six weeks after he left the hospital. The weakness had been progressive for the past five months, at the beginning of which time his legs became rather suddenly weak one day when walking and he fell. After walking a short distance the legs began to feel numb and the knees gave way so that he fell, but on being assisted to rise he could resume walking. His eyelids dropped at times, he saw double on looking to the left, speech became more and more difficult and indistinct during a conversation, he experienced difficulty in chewing and in swallowing, and liquids had occasionally regurgitated through the nose; he was also liable to attacks of dyspnœa and faintness, sometimes quite apart from any exertion.

Mr. RUSHTON PARKER showed a man, aged 30 years, whose Left Elbow he had Excised three years ago for Ankylosis following injury. The result was an unusually strong joint with all the movements perfect. The internal condyle had not been removed.

Dr. F. E. BATTEN showed a case of Myositis. The patient was a man, aged 51 years. In 1889 he had an attack of right hemiplegia from which he gradually recovered under anti-syphilitic treatment. About the beginning of 1900 he woke up one morning and found his left shoulder swollen and painful and at the same time he lost power in the left leg (slight left hemiplegia). In a few days the left leg was well again, but since that time the left arm had gradually become rigid. Dr. Batten saw the patient first in September, 1900, and his condition was as follows. The left shoulder-joint was firmly fixed and all movement took place by rotation of the scapula. The arm was abducted and flexed at the elbow to a right angle. This, however, could be extended another 45 degrees. This extension seemed to give rise to very little pain. The hand could be moved freely. The muscles chiefly affected were the deltoid, supra- and infra-spinatus, triceps, pectoralis major, and biceps. The muscles were extremely hard and rigid but not tender. Voluntary power in the muscles was still good and passive movement gave rise to no pain.—Dr. J. A. MASTERS asked what evidence there was that the paralysis was of central origin.—Dr. H. A. CALEY asked if any bone was present in the hardened muscle.—Dr. BATTEN replied that a radiograph had been taken and it showed no osseous change. The central origin had been inferred from the patient's own account and from altered great-toe reflex.

Dr. LAURISTON SHAW showed a man, a ship's cook, aged 21 years, suffering from Aortic Regurgitation due to rupture of a healthy valve. In December, 1899, while at sea, he was lifting a heavy saucepan full of soup when the ship gave a sudden lurch and in trying to prevent the saucepan from upsetting the patient put forth all his strength and immediately felt a severe pain in his chest and became faint and collapsed. He remained in his berth for two days till the steamer reached Hamburg, where he was admitted to hospital and continued as a patient for seven months. On his return to England he presented himself for treatment at Guy's Hospital on account of dyspnœa, palpitation, and occasional cardiac pain, and was found to be suffering from aortic regurgitation.

Dr. A. M. GOSSAGE showed a case of Dextrocardia, probably Congenital. The patient was a woman, aged 46 years, a tailoress, who complained of weakness and palpitation on exertion. Ten years ago she had rheumatic fever. On examination the heart was found to be in the right thorax. The apex-beat was apparently in the fifth space internal to the right nipple. The superficial cardiac dulness extended up to the fourth costal cartilage and towards the left to the mid-line of the sternum. The liver dulness was in its normal position on the right side of the body, and the stomach seemed to be in the normal position on the left. The two sides of the thorax moved equally and neither side was contracted. No abnormality was found in the lungs by physical examination.

Dr. J. PORTER PARKINSON showed a case of Unusually Great Dilatation of the Heart. The patient was a man, aged 22 years, who had always been delicate, who had rheumatic fever when 12 years old, and had had two subsequent attacks. There were slight pulsation in the right jugular vein and pulsation to the right of the sternum and in the epigastrium. There was præcordial bulging; there were a rough presystolic and a blowing systolic murmur at the heart's apex which was in the fifth space in the mid-axillary line.—Dr. A. MORRISON thought that the apparent amount of cardiac dilatation might be increased by a rachitic kyphotic deformity of the chest.—Dr. WILLIAM EWART observed that the left auricle might be so greatly dilated that it projected on the right side of the heart.

Dr. NEWTON PITT showed a man, aged 32 years, suffering from Combined Sclerosis of the Spinal Cord. There was a history of syphilis. He was now completely anæsthetic and analgesic up to the knees and elbows and had complete loss of muscle sense. He was extremely ataxic in the hands and legs without wasting. There were headaches and internal strabismus of the right eye.—Dr. WILLIAM HUNTER suggested that the sclerosis might result from the transverse myelitis, the outcome of syphilis, and that alcoholism might account for some of the symptoms.

Dr. F. C. EVE showed a Simple Form of Electric Light and Bath. The apparatus consisted of three ordinary electric lamps of 32-candle power fixed on a wooden base and protected by a wire cage. It could be connected by a flexible wire with any domestic lampholder without risk of injuring wires or blowing fuses. The limb, apparatus, and a thermometer were all placed together inside a chamber formed of blankets thrown over an ordinary cradle. The temperature of the chamber rose in from 15 to 30 minutes to from 200° to 250° F., and the bath could be continued for from 30 to 60 minutes.

Dr. C. E. BEEVOR showed a case of Multiple Fibro-Neuromata or Recklinghausen's Disease. The patient was a girl, aged nine years, who had numerous small tumours scattered over the body. They were in the main subcutaneous and the skin could be moved freely over them. They were small and in chains like beads on a string. For the most part they lay in the course of nerve-trunks and

were tender when handled.—Dr. ROLLESTON said that a curious atrophy and pitting of the skin over the tumours in these cases had been observed. In the fully-developed form of Recklinghausen's disease pigmentation and molluscum fibrosum were present.—Dr. BEEVOR, in reply, said he had observed the symptoms referred to by Dr. Rolleston in this case, which he regarded as being in an early stage of the affection.

Dr. J. S. RICHARDS showed a man, aged 30 years, suffering from Chronic Symmetrical Swelling on the Upper Part of both Tendines Achillis. He had served for 12 years in the army and had lived much abroad. He had had ague and syphilis with gonorrhœa. Iodide had not reduced the swellings, which first appeared six years ago.

EPIDEMIOLOGICAL SOCIETY OF LONDON.

The Prevention of Water-borne Enteric Fever amongst Armies.

A MEETING of this society was held on Jan. 18th, Dr. PATRICK MANSON, C.M.G., F.R.S., the President, being in the chair, when Dr. LOUIS C. PARKES and Dr. S. RIDEAL, D Sc., communicated a paper upon a Suggested Method of Preventing Water-borne Enteric Fever amongst Armies in the Field, which was published in full in THE LANCET of Jan. 26th, p. 234.

In the discussion which followed Major W. G. MACPHERSON, R.A.M.C., said that the incidence of enteric fever amongst the troops in South Africa was not so great as amongst the United States troops encamped in the Southern States in 1898 or amongst the Prussians investing Metz. The five worst months in South Africa were from March to July, and during that time 5·8 per cent. of the average strength were admitted to hospital with enteric fever. During the five months the American troops were encamped 10·4 per cent. were admitted with "certain" enteric fever, 19·2 per cent. with certain and probable enteric fever. The worst two months in any place in South Africa were April and May at Bloemfontein. During these months 3·5 per cent. of the troops there were admitted with enteric fever. During the two months in which the Prussian army invested Metz 5·2 per cent. of the investing army were admitted according to his calculations. As regards the probability of lessening enteric fever in armies by sterilising drinking water, he pointed out that drinking water was not the paramount factor in the production and spread of the disease in campaigns. Troops constantly on the move seldom got seriously affected with enteric fever. The disease was essentially a disease of standing camps and the report of the board of medical officers appointed to investigate the origin of enteric fever in the American camps emphasised the fact that specific infection of latrines was the paramount factor, and that it was from the latrines by other agencies than water that the disease was spread. Although, therefore, he did not for a moment wish to minimise the necessity of providing a pure and disinfected water-supply, he doubted whether action in that direction would very greatly decrease the incidence of enteric fever in the field. As regards purifying water-supplies, chemical methods, as suggested by Dr. Parkes and Dr. Rideal, were well known, and he thought at one time these would prove the real solution of the difficulties met with in sterilising water during a campaign. He had already investigated at least five different methods—namely: (1) the German, or bromine method; (2) the Austrian, hypochlorite of lime; (3) the French, Lepeyrire's method, which consisted in carrying in a case fixed in the water-bottle a powder containing permanganate of potash, carbonate of sodium, carbonated lime, and alum; (4) the Belgian, Professor Bergé's method of evolving peroxide of chlorine by adding one or two drops of sulphuric acid to some crystals of chlorate of potash in a flask, and, by means of two tubes inserted through the cork, the one connected with the bucket of water and the other with a bicycle pump, pumping the gas into the water; and (5) the Indian, or permanganate of potash method. The first method was tried in the Soudan expedition of 1898 and did not prove suitable for use with the troops. Soldiers could not be expected individually to break a capsule of bromine into the water, wait five minutes, then add a soloid of hyposulphite of sodium and carbonate of sodium to remove the taste and colour of the bromine, and wait till that was effected before drinking. The hypochlorite of lime method was abandoned because the quantity required to sterilise would affect the taste of the water and because the reagent would not make up in convenient tabloid form. Permanganate of potash had been tried very extensively in India and also in South Africa and had been abandoned because it, too, did not destroy the bacillus typhosus. Professor Bergé's method was obviously not well adapted for individual use with troops in the field. Having had all these difficulties to face in connexion with chemical methods of disinfection the army was provided for the South African campaign with an excellent single-candle pump filter manufactured by the Berkefeld Filter Company. The filter was supplied to each unit of 100 men and filtered 34 pints in 10 minutes. It was known that difficulties would arise in using this filter when there was muddy water, but instructions were issued with each filter explaining these difficulties and stating how it should be used. He had reason to believe that where these instructions were carefully carried out or could be rigidly adhered to there was a very great measure of success. He welcomed, however, the suggestions and experiments of Dr. Parkes and Dr. Rideal as their chemical reagent might help the Army Medical Service to overcome the difficulties already experienced with regard to chemical methods of disinfection. He feared, however, that if it were made up in tabloid form, with a small quantity of adhesive material so that it might dissolve more rapidly, the tin of tabloids in the soldier's haversack would be converted into a tin of powder after the first day's march. The Berkefeld filter weighed 50 lb., and this would be a single issue for every 100 men; the tins of sodium bisulphite tabloids would mean an issue every fortnight or so of quantities weighing 25 lb. for every 100 men and would involve an enormous continuous supply of tabloids in the case of a large army in the field.

Major FIRTH, R.A.M.C., said that the bromine process had been found very successful and he doubted much whether it had been fairly tried on the Nile.

Major W. BABTIE, V.C., R.A.M.C., from long experience in India and South Africa was convinced that all methods were alike impracticable in the field. Men should be taught to control thirst as long as possible; but water was not the only cause, dust, flies, &c., being important factors.

Mr. WALTER PAKES insisted on the difference between experiments in the laboratory and the conditions of service in the field, and remarked that if men would not wait for filtration they would not for the action of chemicals.

Dr. HARFORD-BATTERSBY had been told by a friend in the Hospital Corps of the Imperial Yeomanry that though not mounted they carried with them on the march of sometimes 25 miles in a day 250 quarts, or over a quart per man, of Berkefeld filtered water, practising self-restraint, and drinking morning and evening only. Among 150 men, though in contact with the sick, they had but six cases, and these were very mild. The City Imperial Volunteers, so far as he knew, neither boiled nor filtered their water and suffered severely.

Captain BRAILEY, a medical man, though a combatant officer in the City Imperial Volunteers, believed that the soldier could be taught to use precautions, if made really to understand the danger of neglecting them, but it was useless to exercise restraint for hours and then drink polluted water. They had boiled their water when they had fuel, but often there was none to be had. He himself had fever. A company could carry a Berkefeld filter, but men scattered over the country could not, though they might each have a box of tabloids. The Imperial Yeomanry, even when obtaining their water by means of Abyssinian pumps, had suffered from enteric fever; the Boers had no latrines and infected dust was doubtless an active cause. He had no experience of acid sulphate of sodium as a steriliser, but with a little sulphuric acid it had been found useful in the treatment of dysentery.

The PRESIDENT had had no experience of military matters but much of human nature and doubted if men devoid of bacteriological and chemical knowledge would persevere in any practice requiring educated intelligence. He should like to know the relative incidence of enteric fever on the rank and file, the combatant, and the medical officers.

Dr. S. RIDEAL had great hopes of the British soldier of the future. The War Office admitted the failure in the field of filters and boiling so far as to try chemicals, but quicklime for the disinfection of excreta was obsolete and useless, whereas sodium bisulphate would be as efficacious for these

as for water. Sulphuric acid should be applied to enteric fæces and urine in the proportion of three-quarters of an ounce to five gallons of the polluted liquid. He thought that 0·06 gramme of bromine recommended by Major Macpherson for a litre of water was not quite enough, but a larger quantity not exceeding two grains of sodium or ammonium bromide, of which from 20 to 30 grains per diem was an ordinary medicinal dose, was not desirable for habitual use. Sodium bisulphate had the advantage of being a "thirst quencher," but if preferred the taste could be neutralised by sodium bicarbonate.

Dr. LOUIS PARKES believed that, however important dust, flies, and soil pollution might be in the spread of the disease when introduced, the first cases mostly arose from water, and thought sterilising by filtering or boiling, though more certain than the method he proposed, was not available for scattered bodies of men. The tabloids would render the soldier independent, and though he might not understand the bacteriology of the disease he would certainly prefer drinking lemonade in place of more or less dirty water. It was not many years since civil medical men were equally hopeless as regards the prevention of enteric fever at home, though it was now looked on as one of the most preventable of diseases.

HUNTERIAN SOCIETY.

Exhibition of Cases.

A CLINICAL evening of this society was held on Jan. 9th, Dr. DUNDAS GRANT, the President, being in the chair.

Dr. SEQUEIRA showed three patients, a man and two women, who had suffered from Rodent Ulcer of the Face for 13, eight, and seven years respectively. These patients had been treated for 10 minutes a day with the x rays. The current employed was of from three to four ampères and the coil was one producing a 10 inch spark. The lamp was placed at a distance of six inches from the part affected. Care was taken to protect the normal skin from the action of the rays by means of lead foil. The results were very good. The ulcers healed up entirely, and finally the raised growing edge disappeared also. Dr. Sequeira strongly recommended the adoption of this method of treatment in all cases of rodent ulcer in which it was impossible completely to remove the growth with the knife. He had had 12 patients under treatment, of whom four were quite well, and in no case had the result been disappointing. It was too early to say anything about recurrence after this method of treatment, but even if it had to be resorted to again the patients were infinitely better off than with a progressive ulceration. In some of his cases Dr. Sequeira had carried on the treatment for several months without any danger to the patient. He believed that so short an exposure as he gave, limited to the growth itself, was not likely to cause the serious sloughing which had occasionally been met with in prolonged exposures.

Dr. JOHN W. OLIVER showed a case of Molluscum Fibrosum. The patient stated that he knew of no member of his family who had similar tumours—his age was 56 years, and at 17 years of age he first noticed their appearance; he thought that they had not increased in number but that they had increased in size. His general health had been good as a rule; as a boy he engaged in outdoor games such as cricket, but his intelligence was not good at present.

Dr. FREDERICK J. SMITH showed a man, 36 years of age, who felt a sudden pain in the right testicle three and a half years ago while at work. The testicle rapidly swelled, but subsided in a few days with rest in bed; the swelling returned on two or three subsequent occasions, but each time the pain soon subsided, only leaving the testicle enlarged. There was no urethral discharge at any time and no history of syphilis. He thought the testis had increased somewhat in size during the last few months, but he had had no further attacks of pain in it. The right testicle and epididymis were enlarged to about the size of a goose's egg; in front there was a little fluctuation as though a small hydrocele were present, but at the back the organ was very hard and knobby as though there were several independent lumps of some neoplasm; the uppermost lump was quite isolated upwards and the spermatic cord itself seemed quite unaffected; testicular sensation was quite absent. Dr. Smith had no doubt that the case was one of tuberculous invasion. The testicle, he thought, was not malignant from the length of time the trouble had existed; it was not syphilitic because there was no history of syphilis and because the nodules were too isolated. He thought the testis ought to be removed.

Dr. SMITH also showed a man, 48 years of age, whose urine was loaded with sugar, notwithstanding which there was a complete absence of unusual thirst or polyuria. There were extensive consolidation and excavation of the upper half of the right lung, and the sugar was only discovered accidentally. The specific gravity of the urine was only 1022, and the quantity was never over two pints.

Dr. SMITH also showed a man, 42 years of age, who 14 months previously began to lose his voice and become hoarse, but had no pain. He had a slight cough at the time which had during the last year grown worse rather than better; he had also lost a little flesh and become somewhat short of breath but had not experienced any other symptoms. On admission examination of his lungs gave absolutely negative results, but the laryngoscope showed extensive ulceration of the left cord with warty nodules on it which were undoubtedly tuberculous in origin. Bacteriological examination of the sputum revealed large numbers of tubercle bacilli, so that the diagnosis was rendered a certainty. The chief point of interest lay in the advanced condition of the laryngeal mischief, while that in the lungs still showed little or no evidence of its presence. The larynx was being treated with lactic acid with considerable benefit to the patient.

Dr. ARTHUR DAVIES, Mr. J. H. TARGETT, and the PRESIDENT discussed the cases.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

Exhibition of Cases.—Chronic Interstitial Nephritis.—Irregularity of the Teeth in Children.

AN ordinary meeting of this society was held on Jan. 18th at the East London Hospital for Children, Shadwell, E., Dr. DAWSON WILLIAMS being in the chair.

Dr. H. MORLEY FLETCHER showed a case of Myosotis Ossificans in a boy, aged nine years, who had suffered for two years from increasing stiffness of the arms and shoulders. There was no history of injury. The muscles of the neck, the shoulders, the upper arms, and one rectus abdominalis contained extensive bony masses. Both great toes were small (microdactyly) and in each the terminal joint was ankylosed. There were exostoses on the bones of the head, on the hand, and on the tibiæ.—Mr. F. C. ABBOTT, Dr. PERCY LEWIS, Dr. EDMUND CAUTLEY, Mr. R. CLEMENT LUCAS, and the CHAIRMAN discussed the case, and Dr. FLETCHER replied.

Dr. FLETCHER also showed a boy, aged 11 years, who exhibited some Anomalous Nervous Symptoms, such as listlessness, urinary incontinence, unsteady gait, dragging of the right leg, obesity, halting speech, nystagmus, post-neuritic optic atrophy, intension tremor of the arms, increased knee-jerks, and distinct incoördination of the lower extremities. Dr. Fletcher considered that the diagnosis lay between disseminate sclerosis and cerebral tumour and was inclined to think that the former was the more probable explanation of the condition.—Dr. G. A. SUTHERLAND inquired as to the condition of the thyroid and the state of the temperature.—Mr. SYDNEY STEPHENSON asked whether the visual fields had been examined and if so whether any alteration had been noted.—Dr. FLETCHER BEACH suggested that thyroid extract should be administered.—Dr. LEONARD G. GUTHRIE thought that the case might be an instance of Little's disease or of Friedreich's disease.—Dr. FLETCHER, in reply, said that the child's obesity precluded any very careful examination of the thyroid. The temperature was normal. The fields of vision had not been taken. The patient had been treated for two months with iodide of potassium, but he would now try thyroid extract.

Mr. H. BETHAM ROBINSON showed a boy, aged four years, suffering from Multiple Arthritis of two years' duration. The evidence, he thought, pointed to the case belonging to the rheumatic group; it especially resembled the form produced by gonorrhœa.—Dr. C. W. CHAPMAN suggested that an injudicious diet combined with stimulants might be the cause.—Dr. A. ERNEST SANSOM said that the case looked to him like osteo-arthritis, possibly connected with syphilis.—

Dr. CAUTLEY inclined to the view that it was an instance of gonorrhœal arthritis and not one of osteo-arthritis.

Mr. ROBINSON also exhibited a patient, aged four years, with Congenital Lymphangiectasis of the Tongue. The mucous membrane of the tongue was much thickened and exhibited clear vesicles. There was no macroglossia. The lower lip showed a "port-wine" discolouration.

Mr. ROBINSON also showed an infant with Curious Congenital Cicatrices over the Left Femur and Both Tibiæ and Fibulæ with Thickening of the Underlying Bone. He thought the cause might be connected with some abnormal intra-uterine pressure or bands.—Mr. ABBOTT thought that the child had had fracture of the femur in utero, probably compound, and that the other scars were due to pressure.—Mr. LUCAS thought that one condition, perhaps compound fracture, might account for all the changes. It looked, in the present case, as if at an early period there had been a compound fracture of the tibia, the fibula, and the femur.—Mr. ROBINSON, in reply, pointed out that the symmetry of the lesions was dead against the fracture theory.

Dr. E. G. GRAHAM LITTLE showed a case of Congenital Imbecility in a child associated with abnormal development of subcutaneous fat. The patient had greatly improved under the administration of thyroid extract and the case probably belonged to the cretinoid class, though some of the characteristic features were lacking.—Dr. BEACH asked particulars as to family history and suggested that the child should be sent to be educated to one of the special schools established by the London School Board.—Dr. CHAPMAN urged that in such children, when allowed to walk about, the bones often yielded under the weight of the body.

Dr. LITTLE also showed a case of Pityriasis Rubra Pilaris of Devergie of 18 months' duration. A water-colour drawing illustrating the condition of the child when first seen and a microscopical preparation demonstrating the histology of the affection were also exhibited.

Mr. ABBOTT showed a boy, aged five years, from whom, seven months ago, he had Removed the Whole Lower Jaw for Total Necrosis (of unknown cause), leaving the periosteum. A complete ring of bone had now been thrown out, including a new condyle. The movements were perfect, the shape was good, and the appearance of the feature was excellent. A set of teeth were to be fitted to the new jaw.—The CHAIRMAN, Dr. CHAPMAN, and Mr. P. SIDNEY SPOKES discussed the case, and Mr. ABBOTT replied.

Dr. GUTHRIE related a case of Chronic Interstitial Nephritis in a girl, aged seven years. The patient, a thin, stunted child, with marked bronzing of the skin, was admitted to hospital on Jan. 6th, 1893, on account of severe headaches, accompanied by vomiting, amaurosis, and vertigo, which had occurred every few days for two months. She had never had scarlet fever or dropsy. The left ventricle of the heart was hypertrophied, the pulse was of extremely high tension, and the radial and brachial arteries were thickened. The urine was copious (from two to three pints a day); its specific gravity was from 1006 to 1010, and it contained from one-twelfth to one-half albumin, and a few granular and hyaline casts. After admission the headaches and other symptoms continued, she wasted rapidly, and the heart increased in size. On the 17th she had two fits with loss of consciousness, rigidity, and convulsions almost entirely confined to the right side. On the 30th she had three more fits of similar character. During the eclamptic period the urine was normal in quantity, from 14 to 18 ounces only, but in the intervals the amount rose to as much as 106 ounces per diem. She became strange in manner on Feb. 4th. She had slight left-sided hemiplegia which had almost disappeared on the next day. She gradually became comatose and died on the 7th. She was never dropsical. On post-mortem examination the heart was found to be hypertrophied and dilated. There were two large hæmorrhages in the right central hemisphere. The arteries generally were thickened and the kidneys showed marked interstitial nephritis. Dr. Guthrie drew attention to the rarity of this disease in children. He had found records of eight similar cases in children between the ages of five and 14 years. The symptoms, course, and termination were precisely similar to those of granular kidney in adults. He supposed that the condition might date from an attack of acute interstitial nephritis in infancy and that syphilis, congenital or acquired, might be a frequent cause of granular kidney.—Dr. SUTHERLAND was not prepared to admit that all cases were due to syphilis.—Dr. SANSOM remarked upon the rarity of interstitial nephritis in children and said that in all reported cases there had been intracranial hæmorrhage. He laid stress upon the value of the cardio-vascular symptoms and deprecated diagnosis based exclusively upon the character of the urine.—Dr. GUTHRIE, in reply, said that syphilis, both congenital and acquired, might be a more frequent cause of so-called "granular kidney" than was generally supposed.

Mr. SPOKES made a communication upon the Irregularity of the Teeth in Children, which was, he said, a matter of more importance than was usually recognised. With respect to that particular irregularity which consisted in one or more of the upper front teeth being "bitten over" by the lower teeth he recommended that the misplaced tooth should be forcibly advanced in one operation with a suitable instrument and considered this a much better plan than the one usually adopted of making the child wear a vulcanite plate for some time. He showed models illustrating cases before and after treatment and also the instrument used.—The CHAIRMAN expressed the thanks of the society to Mr. Spokes for his interesting demonstration and the meeting then terminated.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

Microscopical Demonstrations and Exhibition of Cases.—The Medico-Legal Aspect of Skiagraphy.—Gastric Ulcer Surgically Treated.—Gastric Fistula.

A MEETING of this society was held on Jan. 15th, Mr. F. FARROW, the President, being in the chair.

Dr. F. W. EURICH gave a Microscopical Demonstration.

Dr. JAMES KERR showed two cases of Operation for Disease of the Mastoid Antrum.

Dr. R. H. CROWLEY showed a child with Subcutaneous Rheumatic Nodules.

Dr. C. F. M. ALTHORP showed a child, aged seven years, with a large Cystic Tumour in the region of the Right Breast.

Dr. A. H. BAMPTON showed Crystals of Arsenious Acid obtained from Invert Sugar.

Dr. J. B. HALL read a paper on the Medico-legal Aspect of Skiagraphy. He pointed out that an expert, especially one with good anatomical knowledge, could produce in a skiagram almost any degree of deformity he chose. Whilst skiagraphy was certainly useful in some conditions the process was at the present time so bristling with fallacies that it could only be regarded as a scientific toy. It was most unfortunate that some medical writers had not restrained their enthusiasm and preserved a more judicial attitude towards skiagraphy. The public had come to believe that a skiagram was a representation analogous to a photograph, showing only what existed and nothing more. Skiagrams were being accepted in the law courts as indisputable evidence and without their accuracy being called into question. Mr. Hall urged that a skiagram should not be accepted as evidence without expert testimony to prove that the picture had been taken under such conditions as to exclude the possibility of fallacy. Under present conditions the skiagram was a dangerous weapon in the hands of unscrupulous persons and the profession should take steps to protect itself.

Dr. W. H. HORROCKS read notes of a case of Gastric Ulcer with Perforation. The patient was a woman, aged 25 years, who had been seized with severe abdominal pain while at her work in a factory. She was conveyed to her home in a car, a distance of two miles, and subsequently to the Bradford Royal Infirmary. She had suffered from time to time from dyspeptic symptoms, but had never had hæmatemesis. On admission five hours after the onset of the pain the pulse was 88, small and irregular, and the temperature was 96° F. The abdomen was not distended, but was immobile and tender on pressure. The hepatic dulness was not diminished. A median incision was made above the umbilicus and an ulcer was found on the anterior aspect of the stomach near the cardia and smaller curvature. There was extensive extravasation of gastric contents (particles of food and milky fluid). The perforation was closed by three rows of sutures and the peritoneal cavity was flushed out with sterilised water. A drain was inserted into the pelvis through a suprapubic incision and a gauze plug was carried from the wound down to the ulcer. The operation lasted

one hour and ten minutes. The patient made a good recovery.

Dr. H. J. CAMPBELL and Dr. T. JASON WOOD read notes of a case of Perforated Gastric Ulcer followed by the formation of a subphrenic abscess and associated with serous pleuritic effusion. The patient was a woman, aged 25 years, a weaver, who had suffered for two months from pain after food and loss of appetite. Three weeks before admission to hospital she had just sat down to a meal when she was seized with severe pain in the left hypochondrium and had to be carried to bed. She saw a medical man three days later who found her to be suffering from pleural effusion and removed a quantity of fluid on two occasions. On admission the patient was found to be very ill. She was restless and flushed and had a temperature of 103·8° F. There were signs of fluid at the left base. The heart's apex was in the third left space internal to the nipple line. The heart sounds were normal. The lower part of the abdomen was not distended and it moved with respiration. In the epigastric region there was a rounded swelling, rather prominent, which was indistinctly fluctuant, and over it the percussion note was hyper-resonant. At the lower border of this was a hard rounded edge which was tender and which extended from a little above the umbilicus to the left flank. There was a well-marked anvil note obtained over the resonant swelling. The operation was undertaken by Dr. Wood. After ether followed by chloroform had been given an exploring syringe was introduced into the seventh space in the posterior axillary line and some sanguineous serum was obtained. It was not thought advisable to remove the remainder of the fluid at this time. A two-inch incision was made a little below the xiphi-sternum. The peritoneum was found to be thickened and on opening it a quantity of gas escaped, followed by a pint or more of foul pus. The abscess cavity was well shut off by adhesions. The heart was felt beating in the roof of the cavity, the liver formed the floor and the costal parietes were felt to the left. The cavity was washed out with hot water and a large rubber drain was inserted. The temperature fell at once after the operation and the patient made an uninterrupted recovery and left the hospital at the end of a month. Four days after the abscess was incised 10 ounces of serum were withdrawn from the left pleural cavity.

Dr. ALTHORP read notes of a case of Gastric Fistula. The patient was a woman, aged 50 years, who for 15 months before admission had suffered from abdominal pain and vomiting. On examination she was pale and emaciated. The abdomen was flat. Just below and to the left of the umbilicus was a tender swelling, about three inches by two inches, in the abdominal wall, the further connexion of which could not be determined. In the course of a week an abscess pointed at this spot. An incision was made on Oct. 3rd, 1900, under an anæsthetic and a quantity of thin fœtid pus was evacuated. Even at this time it was not obvious what was the cause of the abscess. The wound in the abdominal wall did not heal and there was found after a time a second collection of pus rather to the left of the former incision. On Nov. 28th this was incised and was found to be rather deeper than the first abscess but outside the peritoneal cavity. In the course of three days the discharge from the second wound was found to consist largely of gastric contents. In a day or two practically all the food taken escaped by the fistula and it was thought that this indicated some stenosis of the pylorus. The patient was rapidly losing ground. On Dec. 7th the patient was put under ether. The stomach was washed out through the fistula which easily admitted the finger. The peritoneal cavity was opened by an incision above and to the right of the fistula and a broad pedicle, three inches by one and a half inches, was found passing from the stomach to the abdominal wall. The portion of the abdominal wall to which the stomach was adherent was isolated by an oval incision and sterilised gauze was inserted to protect the peritoneal cavity from being soiled. This portion of the abdominal wall was then cut away from the stomach. The fistula was then found to be the centre of a large ulcer on the greater curvature near the pylorus. There was no stenosis of the pylorus. The edges of the fistula were freshened and the opening was closed by three rows of silk sutures which, however, had to be passed through greatly indurated tissue. The omentum was drawn over the spot and was fixed there by several points of suture. The abdominal wound was closed by silkworm-gut sutures passing through the whole thickness. There was great collapse after the operation. Rectal feeding and subcutaneous injections of saline fluid were given with good effect. On the third day small doses of brandy and meat essence were given by the mouth. The patient died on the sixth day with symptoms pointing to pneumonia. At the necropsy pneumonia of the right lung was found. The abdominal wound was dry and there had been no escape of gastric contents into the peritoneal cavity. There was apparently no attempt at union in the stomach wound and probably had the patient survived a perigastric abscess would have formed. The pylorus was healthy and was not narrowed by the ulcer. There was no dilatation of the stomach. The ulcer was found to be as described at the operation. The omentum was thickened greatly so as to simulate malignant disease. The report of the microscopical examination showed that there was no evidence of carcinoma.

MIDLAND MEDICAL SOCIETY.—The fourth ordinary meeting of this society was held on Jan. 16th at the Birmingham Medical Institute, Mr. Jordan Lloyd, the President, being in the chair.—The following were elected members of the society: Dr. Violet E. R. Coghill, Dr. A. C. Farquharson, Dr. William Wright, Mr. A. E. Freer, and Mr. J. H. Bennett.—Dr. J. Douglas Stanley showed a man, aged 39 years, with Partial Paralysis of the Right Third Nerve and Right Hemiplegia. The patient contracted syphilis 15 years previously. About the beginning of November, 1900, he noticed some weakness of the right arm and leg and the face was a little drawn over to the left. Some weeks later he noticed that objects appeared double and that he could not get the right eye open. The pupil on the right side was smaller than the opposite and the superior rectus was paralysed. The condition was considered to be due to a double lesion, one involving the left internal capsule, the other in the substance of the right crus.—Mr. Lucas showed six feet of Gangrenous Intestine due to strangulation through a hole in the mesentery. The specimen was from a man, aged 29 years, who walked into the surgery of the Birmingham General Hospital on Oct. 4th, 1900. He had been feeling unwell for five days previously and on the preceding day had felt something suddenly "give way" in his abdomen. He had all the signs of acute strangulation. The abdomen was at once opened and about a pint of blood-stained fluid escaped. A large number of coils of gangrenous intestine were then seen and were found to be due to strangulation through a hole in the mesentery. The gangrenous intestine (six feet) was excised and the ends were united by Murphy's button and the abdomen was flushed with saline fluid. He did well for the first two days, but on the next day (Oct. 7th) he became collapsed and died. Post mortem peritonitis was found starting from the point of union of the intestine and due evidently to leakage. The points of interest were that a man with this enormous amount of gangrenous intestine could yet walk into the hospital, and that it could be excised without difficulty, and that he would in all probability have recovered had there been no leakage from the bowel.—Mr. George Heaton read notes of three recent cases of Successful Nephrectomy. The first was a case of right pyonephrosis following vaginal hysterectomy. The patient was a woman, aged 34 years, who three years before had had her uterus removed by vaginal hysterectomy. Symptoms of trouble in the right kidney commenced soon after the operation and had increased in severity since. On March 9th, 1900, an attempt was made to remove the kidney through the lumbar route. It was found to be impracticable owing to dense adhesions. In December abdominal nephrectomy was performed. The patient made a slow but good recovery. The second case was one of right hydronephrosis due to stricture of the ureter. Nephrectomy by the lumbar method was performed. A stricture was found one inch from the pelvis of the kidney through which a fine probe could be passed. A second stricture existed five inches lower down the ureter. Rapid and complete convalescence ensued. In the third case the patient was a youth, aged 17 years, who had had repeated severe attacks of Renal Hæmaturia and Pyuria. In March, 1897, the right kidney was explored for stone but none was found. In November, 1899, the kidney was again explored and a small caseating patch was found in its lower border. This was excised. The hæmaturia and discharge of pus still continued. Nephrectomy by the lumbar method was performed

on Dec. 7th, 1900. The kidney was firmly adherent to all the surrounding structures and was removed piecemeal. The patient made a good recovery. Mr. Heaton commented on the urea excretion in all these cases. In each case the urea excretion for the first few days after the nephrectomy was very much higher (in two cases double) than it had been before the operation.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—The annual meeting of this society was held at Manchester on Jan. 18th, when the following officers were elected for the year:—President: Dr. T. B. Grimsdale (Liverpool). Vice-Presidents: Dr. Gordon Black, Mr. J. E. Burton, Dr. E. T. Davies, Dr. T. A. Helme, Dr. J. W. Martin, Mr. J. Oakley, Mr. A. A. Payne, and Dr. D. Lloyd Roberts. Honorary treasurer: Mr. R. Favell. Honorary general secretary: Dr. E. O. Croft. Council: Dr. R. W. Beesley, Dr. H. Briggs, Dr. S. Buckley, Dr. T. C. Denby, Mr. W. Fingland, Dr. W. E. Fothergill, Dr. J. E. Garner, Dr. C. N. Gwynne, Dr. J. B. Hellier, Dr. J. Huskie, Mr. R. Thacker King, Dr. J. Lambert, Dr. F. P. B. McDonald, Dr. Ll. Morgan, Dr. S. S. Scott, Dr. A. W. Senior, Dr. W. J. Sinclair, Mr. R. Smailes, Mr. E. W. Thompson, Dr. W. K. Walls, Dr. Sinclair White, and Mr. C. J. Wright. Local secretaries: Dr. John Scott (Manchester), Dr. Arthur Wallace (Liverpool), Mr. W. Thompson (Leeds), and Mr. Sidney Barber (Sheffield).—Dr. A. Stookes (Liverpool) showed three specimens of Malformation of the Fœtus causing Dystocia.—Dr. J. B. Hellier (Leeds) showed two specimens of Uteri removed by Hysterectomy with retro-peritoneal treatment of the stump. In the first case there was a pyosalpinx on one side and a tubo-ovarian abscess on the other. In the other case the operation was performed on account of a rapid increase of the tumour after the menopause. Both patients made a good recovery.—Dr. W. E. Fothergill (Manchester) showed: 1. A Small Ovarian Cyst removed after an exploratory laparotomy in a case of menorrhagia which had persisted for five years in spite of treatment, including five curettings. The bleeding had not recurred. The endometrium removed by the last curetting showed glandular endometritis. 2. A microscopical section of a Growth clinically resembling Deciduoma Malignum; also sections of Decidual Tissue and of Chorionic Villi showing syncytium and Langerhan's layer.—Dr. Arnold W. W. Lea showed a specimen and sections of a Benign Adenoma of the Uterus. The patient, aged 40 years, had profuse menorrhagia and constant pelvic pain for three years following her last confinement. Curetting only gave temporary relief. The uterus was enlarged and adherent and there were tubo-ovarian swellings present. The cervix was divided and a small rounded tumour was felt growing from the fundus. A vaginal radical operation was performed, the uterus, ovaries, and tubes being removed. The patient made a rapid recovery. The section of the growth showed it to be a benign adenoma. The uterus showed chronic glandular endometritis, the right tube showed chronic interstitial salpingitis, and the left tube was converted into a hydrosalpinx. Both ovaries were cystic and there were many adhesions.—Dr. David Owen (Manchester) related a case in which labour had been impeded by a Perineo-Vaginal Fistula which also communicated with the rectum. The perineal aperture was in front of the sphincter ani. During labour while the head was distending the vulval aperture proper an arm became protruded through the fistula. The arm was replaced with difficulty and the head was guided forwards by the forceps. The perineum was lacerated, and this wound and also the fistula, the edges of which were pared, were brought together with sutures.—Dr. W. Walter (Manchester) related a case of Hysterectomy for Myoma of the Uterus. The uterus had become converted into a huge sac from the degeneration and suppuration of the growth so that the physical signs closely resembled those of an ovarian cyst. There were no constitutional symptoms of suppuration.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 17th, Dr. D. Burgess being in the chair.—Dr. R. Wiseman Cunningham showed a small collection of Indian Urinary Calculi.—Dr. Sinclair White showed a case of Extroversion of the Bladder.—Dr. W. T. Cocking showed a woman, aged 44 years, with an Aneurysmal Dilatation of the Right Facial Artery at its commencement. The patient was the subject of granular kidney, marked arterial degeneration, and double aortic murmur. She gave a history of an epileptic attack occurring monthly for the last five months. There was no history of syphilis or acute nephritis, but the patient had had scarlet fever in childhood. She had also had nine normal pregnancies.—Dr. W. S. Porter showed the patients in two cases of Peripheral Neuritis in Beer-drinkers, in one of whom—a woman—there had been considerable pigmentation of the trunk resembling that of Addison's disease, and arsenic had been detected in the beer which she had been drinking. Both of the patients had fortunately sought medical advice early, and under full doses of iodide of potassium, and latterly with the application of the constant current to the limbs, recovery with complete restoration of power seemed fairly assured.—Dr. Porter also showed a case of Ataxic Paraplegia. The patient denied syphilis and there was no definite evidence of it. He attributed his symptoms to an injury to the back eight years previously, but the spinal symptoms proper only commenced about three years ago. There was well-marked Argyll-Robertson pupil with myosis. The knee-jerks were present and there was no ankle-clonus. On admission Romberg's symptom was present and there was inability to walk along a given line, but in both these respects the patient's condition had much improved. The chief complaint was of a burning sensation round the lower part of the abdomen. There was great tenderness on pressure over the vertebral spines from the fourth dorsal downwards. There was no anæsthesia.—Dr. Godfrey Carter narrated particulars of a case of Patency of Meckel's Diverticulum. A primipara was delivered of a small, healthy-looking male child on Sept. 16th last. Before tying the cord it was noticed that it was inclosed in a delicate transparent membrane of about the consistency of the amnion in a funicular process, which extended from the abdominal margin of the umbilicus for a distance of about one inch up the cord. Its contents were dark and fluid. It was left unmolested and the ligature was applied one inch further up on healthy cord—that is, two inches from the umbilicus. On the following day this membranous pellicle had dissolved in part and caused the neighbourhood of the child's abdomen to be besmeared with a thin meconium-looking substance. More of this substance continued to be evacuated from the navel and in a few days it was evident that the discharge was fæcal. Gradual distension of the abdomen supervened and all the symptoms of acute intestinal obstruction with fæcal vomiting. Eight days after birth the child was apparently sinking; there had been no action of the bowels, though to the finger and to bougies the anus and rectum felt normal. Enormously distended coils of bowel could be seen through the thinned abdominal walls. Laparotomy was advised and refused. On the tenth day the bowels began to move slightly and soon moved more copiously, abdominal distension subsided, and vomiting ceased. The child seemed fully to recover and the discharge from the umbilicus ceased. Three months later word was brought that the child had died after four days' illness, "the bowels having come out of the navel."

PLAISTOW AND CANNING TOWN MEDICAL PROTECTION AND MEDICO-ETHICAL SOCIETY.—A meeting of this society was held at the Town Hall, Barking-road, on Jan. 18th, Mr. Percy Rose being in the chair.—After the formal business had been disposed of Dr. T. D. Lister opened a discussion on the Terminations of Tubercle Infection occurring in Childhood. After discussing the channels of infection, insisting upon the importance of the air and food passages, especially mentioning the tonsils and subsequent lymph gland tuberculosis, Dr. Lister went on to say that a large number of cases of tubercle infection remaining undiscovered probably recovered completely, but that, clinically, cases presenting undoubted symptoms were liable to early fatal termination from extension or dissemination. The greatest factors of a fatal termination were dose and environment, the former largely depending upon the latter. There was an increasing consensus of opinion against hereditary predisposition. He instanced two cases of healed glandular and general tuberculosis in infants who had died from other causes at 15 and 18 months. In each the number of healed calcified tubercles and glands was small. It was impossible to say why the process had been arrested in these instances, one presenting strong tuberculous family history, or, as he preferred to call it, family infection. Dr. Lister then spoke briefly of the varieties of fatal terminations as observed clinically and of the importance of early diagnosis in mediastinal tubercle. He called attention to Dr. Hugh Walsham's work with the

Roentgen rays, showing a beautiful series of photographs kindly lent by Dr. Walsham, and preparations of mediastinal tuberculosis from the post-mortem room of the East London Hospital for Children at Shadwell. He made some comments on tissue proclivity for tuberculosis in which there seemed to be a general resistance but a local liability in certain sets of non-vital tissues, and concluded by expressing the view that researches with the object of obtaining an antitoxin for tubercle as a result of the activities of the tubercle bacillus itself would probably prove futile, but that possibly some other bio-chemical immunity and cure would eventually be found.—The discussion was continued by Dr. E. Hay, Mr. H. A. de B. Nelson, and the chairman.—A vote of thanks to Dr. Lister and to Dr. Walsham, to whom the society was indebted for the loan of a very valuable collection of x-ray photographs, brought the proceedings to a close.

FOLKESTONE MEDICAL SOCIETY.—The annual meeting of this society was held on Jan. 4th, when 24 members were present.—Dr. T. Eastes gave an account of the meeting of the deputation appointed by the society to interview the Sanitary Committee of the Town Council.—Dr. W. J. Tyson was unanimously elected President for the third year in succession. Dr. Eastes and Dr. J. Hackney were elected Vice-Presidents. Dr. E. G. Sworder was elected honorary secretary in place of Dr. A. E. Larking, to whom a unanimous vote of thanks was given for the efficient way in which he had carried out his duties during the past two years.—Dr. Tyson read a paper on "Ourselves" in which he referred to the subject of medical etiquette, saying that properly understood etiquette was a mutual benefit to the patient and to the medical attendant. He then spoke on the rights of patients and said that at times medical men were apt to forget them whilst thinking of their own rights. Dr. Tyson thought that in agitating too much for the correction of grievances they might lose some of the advantages they already possessed. At present medical men in this country enjoyed more liberty in their action than members of the profession on the continent. Their influence in the world must be, from the nature of their work, more of a private than of a public character, but this did not make it less powerful or less useful. Lastly, Dr. Tyson spoke of the many advantages of a medical society where all subjects related to medicine, sanitation, and social intercourse could be freely discussed.

IPSWICH CLINICAL SOCIETY.—The annual meeting of this society was held at the Ipswich and East Suffolk Hospital on Jan. 10th, Mr. C. K. Mosely being in the chair. Mr. James Hossack was unanimously elected President for the forthcoming year.—Dr. W. W. Sinclair having resigned the honorary secretaryship, Dr. W. Alexander Gibb was elected in his place.—A vote of thanks was passed to the retiring president and secretary for their services during their terms of office.—A ballot being then held for the election of members of the council for the year the following members were elected:—Mr. Branford Edwards, Mr. J. R. Staddon, Dr. Fowler Ward, Dr. W. W. Sinclair, Dr. H. H. Brown, and Dr. G. Vincent.—The retiring President, Mr. C. K. Mosely, read a paper on Constipation and its Treatment.—A short discussion followed, in which Mr. Hossack, Dr. Fowler Ward, Mr. Staddon, Mr. Branford Edwards, Mr. H. B. Rygate, and Dr. Gibb joined.—Mr. Mosely then replied.—A vote of thanks was passed to Mr. Mosely for his paper.

CLINICAL SOCIETY OF MANCHESTER.—An ordinary meeting of this society was held on Jan. 15th, Mr. F. A. Southam, the President, being in the chair.—Dr. E. S. Reynolds read a paper on the Epidemic Arsenical Poisoning, which was illustrated by a series of lantern photographs.—Dr. Arnold W. W. Lea related a case of Pelvic Sarcoma with Chylous Ascites treated by Abdominal Section and Drainage. The patient was well four and a half years after the operation.

THE Royal College of Surgeons in Ireland has forwarded the following telegram of condolence to the Lord Chamberlain: "The Royal College of Surgeons in Ireland desires to offer to His Majesty the King its profound sympathy with him in his bereavement and to repeat to him the assurance of loyalty and devotion which the College tendered to our late Most Gracious Sovereign during her last visit to Ireland.—Thomas Myles, President; Lambert H. Ormsby, Vice-president."

Reviews and Notices of Books.

Encyclopædia Medica. Under the general editorship of CHALMERS WATSON, M.B., M.R.C.P. Edin. Vol. V. Herpes to Jaws. Edinburgh: William Green and Sons. 1900. Pp. 536.

AMONGST the numerous contributions to this volume a few stand out as being especially worthy of notice, showing signs of careful preparation and a thorough knowledge of the subject on the part of the authors.

Foremost amongst these are the articles on Insanity, of which there are four. The section on Etiology is by Dr. A. R. Urquhart, physician superintendent to the Royal James Murray Asylum, Perth. His opening words indicate very clearly his views on the subject: "The causation of insanity is a highly complex question in detail, yet the broad fundamental facts may be narrowed to two comprehensive statements regarding heredity and stress. The inherent faulty nervous organisation of the individual and the stress of environment constitute the basis of our considerations in regard to this subject." Proceeding to enlarge on the above Dr. Urquhart shows that insanity is a retrogression, a dissolution. It is a reversal of evolution, and as such has its beginnings in the latest evolved structures and functions of the brain. His remarks on heredity are well worthy of study and demonstrate the care with which the author has worked up his material before arriving at his conclusions. The section on Pathology is written by Dr. W. Ford Robertson, director of the Laboratory of the Scottish Asylums Board, Edinburgh. The author discusses the nature of the morbid processes upon which insanity depends—that is to say, its pathogenesis and also its pathological anatomy. He criticises the views held by various authorities as to the effect of morbid conditions of the cerebral circulation on the mental faculties, holding that there are reasons for believing that cerebral hyperæmia in mental diseases is essentially only a part of a complex pathological process and that it is not in itself a primary cause of the cerebral disorder. Dr. G. R. Wilson, physician superintendent of the Mavisbank Asylum, Edinburgh, contributes the section on the Nature and Symptoms of Insanity, and gives an excellent account of the various clinical types of the disease, his remarks on the "insane diathesis" being specially interesting. The section on Treatment is by Dr. C. A. Mercier, lecturer on insanity at the Westminster Hospital Medical School.

The account of Hysteria is also divided into sections, each by a different author. Dr. Paul Sainton (chef de clinique adjoint à la Faculté de Médecine, Paris) is responsible for the chief section with the title, "General Article on Hysteria." The author naturally finds a difficulty in finding a definition of the disease, but aptly expresses himself thus: "Briefly, hysteria is a neurosis of many and perplexing varieties and of pyschic origin, whose disorders often simulate organic disease." In his description of the more prominent types the symptoms are grouped according to the systems or organs of which they indicate functional derangement. The story of the phenomena is arranged rather differently than we are accustomed to see in English text-books and is more interesting to read on that account. We are not informed whether we are presented with a translation or whether Dr. Sainton wrote in English, but the language employed is very clear and precise. We particularly commend the description of the condition known as "hysteria major," or "attack de la Salpêtrière." The different phases are arranged in the form of a table borrowed from Charcot and modified by Grasset. In describing the treatment of hysteria the author mentions hypnotism, but speaks of that method with some reserve. He says:

"Hypnotism is a valuable aid in the treatment of hysteria, but it must not be considered a panacea: numbers of hysterical patients are not hypnotisable. On the other hand, hypnotism itself is not without danger, for repeated *séances* act as a form of attack." The last remark is certainly interesting; French observers have more opportunities of observing the results of hypnotism than have physicians in this country and the recognition of the fact just referred to is of considerable importance. A short article by Dr. G. F. Still is also of interest as showing that hysteria is much commoner in children than is generally supposed, and it is a matter of no small moment that its frequency should be recognised, for in the early years of life environment, one of the most potent factors in hysteria, is easily modified and controlled; moreover, as the author points out, education in its widest sense can be carefully planned, even in its smallest minutiæ, so as to guard against neurotic tendencies at that period when they are most easily checked. The third contribution on hysteria is by Dr. A. G. Miller, consulting surgeon to the Royal Infirmary, Edinburgh. It is entitled "The Surgical Aspects of Hysteria," and by this the author understands those conditions "in which there is imagination, imitation, or exaggeration of pathological affections." The main difficulty is naturally one of diagnosis, for upon this the treatment depends, and Dr. Miller sums up his remarks thus: "If the case be hysterical treat the hysteria. If, on the other hand, you have any suspicion that even a trace of disease is present treat the local affection. It is the less dangerous mistake of the two." This is sound advice, but it is frequently most difficult to determine whether a joint affection, for example, is functional or organic or the two combined, that is to say, a functional exaggeration of a pathological condition.

There are several other contributions in this volume that deserve more lengthy notice than we can give. Mr. D'Arcy Power writes on Injuries of the Hip-joint, and Mr. Alexis Thompson on Diseases of the Hip-joint; both papers are excellent. Dr. J. Milne Bramwell contributes a well-written article on Hypnotism. It is not an easy subject to comment on, but the author is very moderate in his views and states at the outset that it is in functional nervous disorders that hypnotism yields its best results. Dr. A. Lockhart Gillespie is responsible for the broad subject of Indigestion. The amount of ground which he has to traverse is shown by his table of "classification," no less than 47 types being mentioned. The author explains that the "classification" is meant to indicate the mode of origin and the nature of the primary cause of the various chief types of indigestion, apart from the many forms in which more than one of these factors co-exist, and from those in which different symptoms are produced by similar causes.

Amongst other contributors to this volume are Dr. J. J. Pringle (Herpes and Ichthyosis), Dr. H. Ashby and Mr. G. A. Wright (Hydrocephalus), and Mr. W. Armstrong (Hydropathy). Professor Hans Buchner of Munich writes a valuable contribution on Immunity.

Taken as a whole this volume is a very good one, and will materially add to the value of the series of which the "Encyclopædia Medica" will be composed.

The Child: a Study in the Evolution of Man. By A. F. CHAMBERLAIN, M.A., Ph.D. With illustrations. The Contemporary Science Series. London: Walter Scott. 1900. Pp. i.-xii. and 495. Price 6*s*.

THIS book is an endeavour to present to the reader, on the one hand, data obtained by the study of children, and on the other hand certain ascertained facts concerning the evolution of man, with the object of affording explanation of the psychological development of the human race. The child is studied from an anthropological point of view mainly with regard to his psychological characters rather than as an object for physiological examination and description, while analogies between the child and the lower animals are suggested. A leading idea is often useful as a guide to observation and to the arrangement of other men's opinions as they may appear to afford mutual explanations and show the meaning of phenomena. Evidence can thus be arranged in support of, or in contravention of, an hypothesis. The doctrine of evolution in nature affords a leading idea which serves to connect the facts of recent observations on children.

In the book before us the headings of chapters, in the absence of a clear statement of the purpose of each, leave some doubt as to the nature of the problems suggested for demonstration. The method of the author appears, however, in the opening chapters on the Helplessness of Infancy and the meaning of Youth and Play, where a large number of opinions of philosophical interest are quoted and where the results to the perfect organism of early weakness in childhood are displayed in considerable detail. Prominence is given to the views of Mr. Fiske as to the social results of the protracted period of helplessness of childhood, leading to prolonged dependence of the offspring upon their parents. It is, however, a bold conclusion to say (p. 441) that this is nature's device to ensure the sociality of the race; but we readily agree with the dictum quoted from Schleiermacher: "Being a child must not hinder becoming a man; becoming a man must not hinder being a child," as a principle of wide application in educational training.

Signs, gestures, language, and the artistic expression of children are well described and their description forms one of the best sections of the work. Elementary sounds as met with among children of various nationalities and savage tribes are followed in their development into words to which a definite significance becomes attached. The record of children's vocabularies at successive ages, indicating mental growth and educational achievements, is a good piece of work; this subject is worthy of considerable extension and study. Many types of childhood are described on a psychological basis, with quotations from Siegert, Scholz, Sesshaft, and other authorities. But for the purposes of studying evolution we think a natural classification of children preferable. Methods of observation should be employed more analogous to those used in natural history, based upon physiological characteristics, added to which the mental status may be described. Anthropometric and physiognomical description (with the signs which indicate the general characters of brain development, such as spontaneity, coördination controlled through the senses, and the relations in which they appear), present types of children that may be recognised by any observer and student under variations of environment. Speaking of women and children Dr. Chamberlain quotes many facts in embryology and development of the body, and discusses the obscure question of the origin of sex without throwing much light on the subject. His descriptions of the differences between boys and girls are more instructive. Boys he shows to be more liable to all forms of irregular and subnormal development, while the persistency of tendencies in woman is said to be less than in man. The general conclusion arrived at is that under the present conditions of civilised life there is a tendency to "an approximation of man and woman, which represents the highest effort of the race to make the best of life in all its varieties and vicissitudes." This may be so: the latest British census shows a nearer equality in the duration of life in men and women, and a more equal number of illiterates, and in each case the improvement is to the advantage of women.

Throughout the book there are indications of the dominant idea of evolution as a guide to child-study.

The chapter entitled "The Child as Revealer of the Past" contains an epitome of the anatomical and physiological resemblances between animals and children, and discusses also the common points in their psychological development, and the explanations offered illustrate the similarity of natural processes in all living things. The suggestion arises that the methods of observation and description employed in natural history should be more strictly followed in studying evolution of the child. We cannot agree with the opinion quoted from Papillault that a growth in width of the cerebral lobes, exerting upon the skull a centrifugal pressure, keeps the two frontal lobes separated. It is now acknowledged by pathologists that defective brain development and microcephaly are frequently accompanied by premature ossification and other bony defects, but it is known that intra-cranial pressure is not the main factor in the case.

Infancy and childhood in their physiological aspects present problems of increasing interest and importance, in following which the application of the hypothesis of evolution in nature will prove a useful guide, enabling observers to correlate brain growth with psychological development, thus affording explanation of many phenomena and giving new knowledge. The book would have been more useful to the student of evolution had a table of contents and a fuller index being given.

Die Mechanik des Hörens und ihre Störungen. (*The Mechanics of Hearing and Their Disturbances.*) By Dr. Med. GUSTAV ZIMMERMANN, Dresden. Wiesbaden: J. F. Bergmann; Glasgow: F. Bauermeister. 1900. Pp. 110. With four Illustrations in the text.

THIS is an important addition to the literature of an intricate and difficult question. The justly celebrated work of Helmholtz is fairly familiar to Englishmen; but often, it is to be feared, the first casual glance at his work has comprised the knowledge obtained, as the abstruse mathematical calculations are beyond the reach of too large a number. Dr. Zimmermann has spared us any such slough of mathematical despond. To take one point that will be familiar to most, the description by Helmholtz of the cog action of the malleo-incudal articulation, undoubtedly correct in its main contentions, was by reason of the wording of the original reading tedious and far from clear. Dr. Zimmermann not only corrects Helmholtz, but at the same time renders the suggestions he puts forward clear, both by reason of the conciseness of his style and by means of the very excellent diagrams. This is a work that will repay study, and it appears to be one that might be reproduced with advantage in English.

Reports to the Malaria Committee of the Royal Society. Third series. London: Harrison and Sons. 1900. Pp. 45. Price 2*s*.

THIS publication contains several reports from observers who have been studying malarial fevers, more especially from the point of view of etiology. Dr. J. W. W. Stephens and Dr. S. R. Christopher present reports on the following subjects: "The Agglutination of Sperozites (preliminary note)"; "The Malarial Infection of Native Children"; "On the Destruction of Anopheles in Lagos"; "Note on Malarial Fever on Railways under Construction"; and "The Segregation of Europeans." The second-named is perhaps the most interesting—"The Malarial Infection of Native Children." In a previous report the authors had given the results of their examination of the blood of a number of natives, having regard mainly to the relation between the age of the children and the percentage of those infected; in the present report they consider rather the character of the infection itself and the variations that occur in it from time to time. In natives they consider that two conditions are met with: 1. A condition of infection of young children without febrile disturbance. Dr. Stephens and Dr. Christopher suggest that this may be due to a natural insusceptibility of the native African to malaria or to an immunity transmitted from the parent to the offspring. 2. A condition of active immunity in the adult native—an immunity acquired as the result of many years of infection with parasites. The immunity is accompanied by a progressively scantier development of parasites, and is quite comparable to that described by Pawlowsky for infection with micro-organisms.

Dr. C. W. Daniels contributes reports on Distribution of Anopheles in Lower Shire, Zambesi, and Chinde Rivers; Distribution of Anopheles Breeding-Grounds in the British East African Protectorate; Geographical Distribution of Anopheles of Africa; and Prophylaxis. In the last-named contribution many useful suggestions are made as to the protection of Europeans from malaria. The author considers that whilst it is impracticable to exterminate the anopheles, yet in certain localities the number of them could be greatly reduced by larvicides and attention to drainage. Nevertheless, the main reliance in many places must be placed on protection from the bites of mosquitoes, and Dr. Daniels proceeds to describe the most desirable forms of houses and mosquito-proof rooms and of mosquito nets. These reports form interesting reading and add considerably to our knowledge in the spread and prevention of malaria.

Die Arzneimittel Synthese auf Grundlage der Beziehungen zwischen Chemischem Aufbau und Wirkung: für Aerzte und Chemiker. Von Dr. SIGMUND FRANKEL, Docent für Medicinische Chemie an der Wiener Universität. (*Synthetic Remedies and the Foundation of their Relationship between Chemical Structure and Action: for Physicians and Chemists.* By Dr. SIGMUND FRANKEL, Lecturer on Medical Chemistry in Vienna University.) Berlin: Julius Springer. 1901. Pp. 576. Price 12 marks.

THIS volume deals with an important and fascinating subject. The architecture of molecules undoubtedly determines the nature and action of the group containing these molecules. In the case of well-defined substances it is probable that pharmacology and therapeutics will rest upon a more definite basis as it becomes known in what manner the constitution rather than the composition of these substances determines their action. Already we know that by varying the positions of a certain group of atoms in the molecule a new substance may be obtained which, though having precisely the same percentage composition and the same elements present, is quite different in its chemical and therapeutic action. In the work before us the author deals with this interesting aspect of constitution in relation to therapeutic action. The coal-tar industry has been the means of placing so many synthetic remedies at our disposal as to have rendered service at any rate in one direction—namely, of affording plenty of material for study and trial. Of course, synthetics are very limited in kind and in number in the inorganic world. The carbon compounds, however, appear to give rise to an endless series. The work is divided into a general part and a special part. In the former the author deals first with the action of inorganic and organic bodies. This is followed by a consideration of the action or of the part played by single atomic groups. The hydrocarbons of the paraffin series are next considered, and then the significance of the hydroxyl group, the alkyl groups, the cyanogen groups, the nitro groups, and so on. An interesting comparison is drawn between the action of ortho-, meta-, and para-derivatives. The second part relates to the consideration of well-known remedies, comprising antipyretics, alkaloids, hypnotics, antiseptics, and a few special substances like the glycerophosphates and ichthyol. The work is an excellent contribution on the subject and, as we have said, the question of

molecular constitution grows steadily in importance in its relation to the action of remedies. We should welcome an English translation.

Die Urogenitalmuskulatur des Dammes mit besonderer Berücksichtigung des Harnblasenverschlusses. (*The Urogenital Musculature of the Perineum, with Special Reference to Closure of the Bladder.*) By Dr. OTTO KALISCHER. With 39 Coloured Illustrations in the text and 33 Plates. Berlin: S. Karger. 1900. 8vo, pp. 184. Price 13*s.* 6*d.* net.

THIS book consists of an account of the author's researches upon the musculature of the pelvic floor, with special reference to the urethra and the sphincter vesicæ. It is divided into three parts. The first part deals with the striated muscle of the urethra in the male, the second part with the striated muscle of the urethra in the female, and the third part with the smooth musculature of the same structure in both the male and the female. The book is illustrated by 33 plates of sections and 39 coloured illustrations in the text. As the author points out, in spite of the large amount of work which has been done upon the subject the descriptions by different anatomists of the course of the muscles described in this work vary very greatly from one another. He attributes this to the fact that in many instances the conclusions have been drawn from macroscopic examinations alone and it is only of recent years that the microscope has been called in to help.

How inaccurate the results arrived at by naked-eye examination are likely to be is shown by the fact that in the sub-pubic angle it is often impossible without the aid of the microscope to distinguish between muscle tissue and connective tissue. Dr. Kalischer's own conclusions are mainly based upon the microscopic examination of series of sections taken through the urethra, bladder, and surrounding parts. As the arrangement of the musculature is much less complex and more distinct at an early age the author has devoted a large part of his work to a consideration of the conditions present as regards these particular muscles in the fœtus and young child. From a study of both sagittal and coronal sections the general arrangement of the various muscles of the urethra and perineum is described and then the anatomical relations and attachments of each muscle in considerable detail. A very copious summary of the literature is appended to each part and the whole book shows evidence of much research and hard work. The plates of the sections are well reproduced and clear and the diagrammatic illustrations in the text serve their purpose.

We have not space to consider Dr. Kalischer's conclusions in full, but we can recommend this monograph for perusal to anatomists and others interested in the musculature of this particular region.

LIBRARY TABLE.

Transactions of the Otological Society of the United Kingdom. Vol. I. First session 1899–1900. Edited by CHARLES A. BALLANCE, M.S. Lond., F.R.C.S. Eng., and ARTHUR H. CHEATLE, F.R.C.S. Eng.—The first volume of these transactions gives the rules and regulations of the new society and a list of officers and members. The report follows of the first meeting, which was held on Feb. 5th, 1900. At this meeting the address of the President, Sir William Dalby, on the Present Position of Aural Surgery, was delivered. The address appeared in full in our issue of Feb. 10th, 1900, and is here repeated. A paper by Dr. Urban Pritchard follows, upon Aseptic Purification of the Meatus and Adjacent Parts, both for operation and as a treatment in chronic middle-ear suppuration. Dr. William Milligan contributes some Notes of a Case of Cerebellar Abscess recently operated on. Dr. Dundas Grant and Mr. A. H. Cheatle contribute cases of Thrombosis of the Lateral Sinus, both operated upon without ligature of the internal jugular vein and in both of which recovery followed. Dr. Ernest Waggett contributes a case of Sequestration of the Cochlea and sundry specimens were shown. Perhaps the most striking case recorded is that dealt with in a paper by Mr. C. A. Ballance at the third ordinary meeting of the society on a case of Epithelial Grafting of the Labyrinth after Removal of the Semicircular Canals. The patient, a woman, aged 54 years, was completely deaf and so vertiginous that she could not walk across the room, yet after operation she recovered her hearing and heard exceedingly well. We congratulate the new society upon the interest of its first volume of published transactions.

Sewage Disposal Schemes: Table of Local Government Board Requirements. By S. H. ADAMS. York: Ben Johnson and Co. October, 1900. Price 2*s.* 6*d.*—Local authorities contemplating any extension of, or alterations to, existing arrangements for the sewage disposal of their districts will find Mr. Adams's Table exceedingly useful. Hitherto there has not been, so far as we are aware, any printed summary of these requirements obtainable that might guide local authorities to an opinion as to the desirability or otherwise of this or that system when applied to their individual case. The Table, though unofficial, is, we think, reliable; it also has the advantage of being clear and concise.

In Nature's Workshop. By GRANT ALLEN. London: George Newnes, Limited. 1901. Pp. 248. Price 3*s.* 6*d.*—This is another collection of the late Grant Allen's charming essays on natural history subjects and is a fit companion to his "Flash Lights on Nature." The present volume deals with among other subjects the devices by which animals, insects, and even the vegetable world protect themselves by mimicry. Here the reader will find something about those insects that really are nasty to eat and have adopted a dress which proclaims the fact to their enemies, and he will also learn about those that are not nasty but dress as if they were so. Others, such as, for instance, the caterpillar of the puss moth, look as if they would bite although they do not. Mr. Enock's illustrations are admirable, and the book is an excellent present for a boy taking an interest in nature. If he lives in the country he can see the creatures and plants alive, and if in London he can go to the Natural History Museum and see, at all events, the colour mimicry.

Vade Mecum de Thérapeutique Chirurgicale. Par le Dr. HENRI FISCHER. Paris: L. Boyer. Pp. 328. Price 4 fr. 50 c.—Dr. Fischer is evidently an enthusiast in his art. He points out in his preface how the field of surgery is widening every day and how necessary it is for all medical men, especially provincial practitioners, to keep their surgery green. The book does not pretend to give an account of all operations, but only, as the author says, of the more usual everyday kind. To this end he has endeavoured to give the practitioner a succinct account of things which it is indispensable that he should know. After an account of asepsis and antisepsis, of how to prepare dressings and get ready for an operation, Dr. Fischer goes on to consider anæsthetics and minor surgery. The various organs of the body are then taken in turn, beginning with the eyes, nose, and ears. Most of the operations on these organs, together with the conditions which make them necessary, are shortly and clearly described. The book should, we think, prove very useful as an *aide memoire*, but it rightly presupposes a sound surgical and medical training.

1. *The No Breakfast Plan and the Fasting Cure.* Pp. 208. Price 4*s.* net. 2. *The Radical Cure of Chronic Alcoholism.* Pp. 76. 2*s.* net. By RICHARD HOOKER DEWEY, M.D.

Published by the Author at Meadville, Pa., U.S.A. London: Gay and Bird. 1900.—Of these two little books the second is practically made up of excerpts from the first, put together in lecture style. Dr. Dewey's theory is, to put it briefly, that most people eat too much, that breakfast is a mistake, except apparently that he allows a cup of coffee, and that sick people should not eat or be fed until they wish to eat. Fasting, too, we gather will cure the craving for alcohol. There is no doubt that the majority of people eat too much. As for Dr. Dewey's "no breakfast" theory, it is, after all, not new, for in most southern countries, and even in northern France, but little more is taken on rising than a cup of coffee or chocolate. We are glad to see that Dr. Dewey lays stress upon a point which is too often forgotten—namely, that milk is mainly a food. True, he argues that milk is not a food for man after the coming of the molars, an idea with which we venture to disagree. As for the cases which Dr. Dewey cites of persons fasting entirely from food for 30 days or so, going about their work all the time and feeling very much better, we can only echo Dr. Shrady's remark on pages 133 and 134 about Mr. Rathbun's case, "Well, it's remarkable. But I sincerely hope Mr. Rathbun will have no imitators."

A Handbook of Sanitary Law for the Use of Candidates for Public Health Qualifications. By B. BURNETT HAM, D.P.H. Cantab., M.D. Brux., M.R.C.S. Eng., L.R.C.P. Lond. London: Ash and Co., Limited. Pp. 148. Price 2*s.* 6*d.*—In the second edition of this useful little work the author has added the Sale of Food and Drugs Act, 1899. The various subjects under the control of the sanitary authority are dealt with *seriatim*, the definition being followed by an explanation of legal procedure. Dr. Ham holds that sanitary law is the bugbear of the D.P.H. student. It may be so, but in our experience, though irksome, it is not regarded as comparable in difficulty with the science required for the diploma. This little work will prove a valuable addition to text-books on this subject.

We have received from Mr. H. J. Paterson, the surgical registrar, a copy of the *Surgical Report of the London Lock Hospital for 1899*. It contains several matters of interest. In the table in which the diseases of the in-patients are classified we see that there were 157 cases of syphilis, 73 cases of gonorrhœa, 16 cases of phagedæna, and 33 instances of "septic sores," 11 of which developed signs of syphilis while under observation. Of the 16 cases of phagedæna it is interesting to see that 11 at no time had any signs of syphilis. Only three deaths occurred in the hospital during the year; two were apparently cases of septic infection and one died from erysipelas. Notes are given of some important cases of early severe syphilis and of late syphilis. Apparently no printed report of the hospital is issued, as the copy we have received is typewritten. We do not remember having received any previous report and commend the diligence which has resulted in this.

Thoughts on Rome and Other Essays. By CONWAY SCOTT. Belfast: M'Caw, Stevenson, and Orr, Limited. 1900.—The author describes the essays from which the little book takes its title as consisting of ideas which floated through his brain while he was wandering through the Eternal City. It consists of a series of contrasts between the City of the Consuls and Cæsars and the Rome of modern times, the Rome in which the Circus Maximus, the most magnificent racecourse in the whole world, is replaced by smoky, grimy, dirty gas-works, continually belching forth a smoke which offends the eye and sickens the soul. The whirligig of time has caused some of the contrasts to be ludicrous and may afford food for meditation. "National Health," a term which the author uses in its widest significance, and "Sir Henry Lawrence" are the titles of other essays which may be read with interest.

Analytical Records

FROM

THE LANCET LABORATORY.

BETA-NAPHTHOL TABLOIDS.

(BURROUGHS, WELLCOME, AND CO., SNOW-HILL-BUILDINGS, LONDON, E.C.)

BETA-NAPHTHOL is a powerful antiseptic which has been used as an anti-fermentative throughout the alimentary tract. It has been used with advantage in diarrhœa and dysentery and in fermentative dyspepsia. It is also said to be useful in influenza. The tabloid contains three grains of beta-naphthol and this form of the drug is convenient for administration. The tabloid readily falls to powder after a few seconds' immersion in water.

MUNICH, PILSENER, AND LAGER BEERS (SCOTTISH BREWED).

(J. AND R. TENNENT, WELLPARK BREWERY, GLASGOW.)

These beers are brewed in Scotland and they are very excellent, wholesome, and palatable products. The Pilsener beer which is intended for export gave the following results on analysis: extractives, 4·58 per cent.; mineral matter, 0·19 per cent.; alcohol, by weight 4·00 per cent., by volume 5·00 per cent., equal to proof spirit 8·77 per cent. It is a very light beer and more heavily bittered than the other examples. The Munich beer gave the following results: extractives, 6·83 per cent.; mineral matter, 0·25 per cent.; alcohol, by weight 4·00 per cent., by volume 5·00 per cent., equal to proof spirit 8·77 per cent. This possesses the well-known characters of Munich beer. It is a dark-brown beer containing a high proportion of nutritive malt extractives, although its alcoholic strength is relatively low. The Lager beer gave the following results on analysis: extractives, 4·52 per cent.; mineral matter, 0·23 per cent.; alcohol, by weight 4·00 per cent., by volume 5·00 per cent., equal to proof spirit 8·77 per cent. This is an excellent, palatable beer, bright and in good condition. We could find no objectionable preservative in these beers and a careful search for metallic contamination, including arsenic, gave negative results. It is evident that beers can be produced in the United Kingdom (in Scotland in particular) equal in excellence to the well-known German beers, light in alcoholic strength, wholesome, and palatable.

SIDONAL.

(R. W. GREEFF AND CO., 20, EASTCHEAP, LONDON, E.C.)

Sidonal is one amongst the many new remedies proposed for gout. Chemically it is quinate of piperazine. Its preparation was suggested by the fact of the presence of a principle in fruits, the consumption of which has something to do with effecting a very marked reduction in the amount of uric acid. This principle has never been definitely identified, although a number known to exist in fruits have been suspected; but quinic acid, a frequent, although minor, constituent of fruits, is found to be powerful in reducing the output of uric acid. It would appear that pure quinic acid is not suitable for administration, and so it was combined with the organic base piperazine—itself a uric acid solvent—the product being quinate of piperazine or "sidonal." An interesting paper in the *Berliner Medicinische Wochenschrift*, March 12th, 1900, records some excellent results gained on its administration in chronic articular rheumatism, and other papers have appeared in the German journals from time to time on the favourable results obtained by the use of sidonal in preventing uric acid deposits and gout. "Sidonal" is said to be harmless. It

is a white crystalline powder, easily soluble in water, but only slightly in spirit. For administration it is made in tablet form, each containing seven and a half grains of the compound.

MAGGI'S TONIC BOUILLON.

(COSENZA AND CO., 95, WIGMORE-STREET, CAVENDISH-SQUARE, LONDON, W.)

The bouillon is contained in a gelatin cartridge and weighs just five grammes, so that six weigh a little over an ounce. The contents of each cartridge or capsule are to be dissolved in one-third of a pint of water and a palatable and nourishing soup is the result. In this instance the nutritious value is enhanced by the addition of an easily assimilable preparation of iron. According to our analysis the amount of iron is 1·44 per cent. calculated as ferric oxide. The proximate analysis of the bouillon gave the following results: moisture, 12·28 per cent.; mineral matter, 52·50 per cent.; and organic matters, 35·22 per cent. (consisting of the nutritious and stimulating principles and salts of meat). We have elsewhere shown that the bouillon is a real nutrient and the presence of an assimilable preparation of iron adds to its value for invalids and especially those whom a course of iron is calculated to benefit.

IRONOL.

(HANS HOFF, 29, NEW BRIDGE-STREET, LONDON, E.C.)

This preparation is described as "liqueur ironol" containing iron, 80 per cent. of which is said to be absorbed. In it the objectionable taste of iron salts is not noticeable, while it is without effect upon the teeth in the manner of ordinary salts of iron. On analysis it yielded the following results: sugary residue, 30·56 per cent.; mineral matter, 0·16 per cent.; oxide of iron (Fe_2O_3), 0·11 per cent. The "liqueur" contained no alcohol. On boiling with an alkali it yielded ammonia. We, therefore, find no novelty in the preparation and are not prepared to admit that it has any advantage over many of the ordinary preparations of iron used in medicine.

"KASSAVA."

(PROSSER DAVIS, 16, GLOUCESTER-ROAD, REGENT'S PARK, LONDON, N.W.)

This is a beverage which takes its name from the fact that it is brewed from cassava starch. It is a bright sparkling beverage, with pleasant and refreshing though somewhat sweet taste. It is agreeably bittered with hops. As our analysis shows it possesses only a very moderate alcoholic strength. The analysis was as follows: extractives, 5·52 per cent.; mineral matter, 0·05 per cent.; alcohol, by weight 0·53 per cent., by volume 0·66 per cent., equal to proof spirit 1·16 per cent. Since cassava meal is regarded to be highly nutritious it may be assumed that this beverage possesses nutritive properties also and it is distinctly palatable. It is undoubtedly wholesome and prepared on scientific lines. The starch is converted into sugar in a natural manner and without the intervention of objectionable substitutes. We found no preservatives in "Kassava," neither any trace of metallic contamination.

NEW TOILET SOAPS.

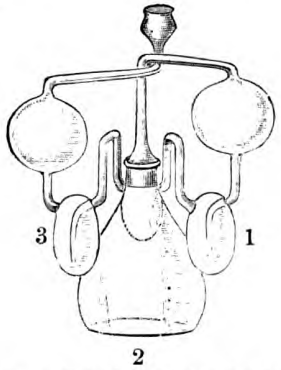
(E. COOK AND CO., EAST LONDON SOAP WORKS, BOW, LONDON, E.)

Under the names respectively of "Throne," "Frontier," and "Boracic" soaps we have received specimens from the above makers. We have already reported upon the excellence of the soaps manufactured by this firm. All are economical soaps because they contain a minimum of water and no foreign substances. Moreover, they contain the highest possible percentage of chemically pure soap without any trace of free alkali, according to the delicate tests we have tried. The boracic soap, of course, contains a mild and harmless antiseptic. The tablets were elegantly scented and are well adapted for toilet purposes and especially for sensitive skins.

New Inventions.

A NEW APPARATUS FOR USING GUTZEIT'S TEST FOR ARSENIC.

THE successful application of Gutzeit's test for arsenic to substances containing sulphites or other compounds liable to yield sulphuretted hydrogen demands extreme care. If the substance does not permit of the elimination of the interfering sulphur compounds, or, at least, the reduction in their quantity below a given point, recourse must be had to some other method for finding arsenic. In the case of articles like beer where the proportion of sulphurous bodies is comparatively small and also easily dissipated, being present as sulphites, the exercise of care and some experience of the conditions under which the test is best carried out will enable the operator to come to a safe conclusion. The use of permanganates, iodine, or bromine, for oxidising the sulphites is not commendable because these bodies are themselves liable to interfere with the test, particularly iodine and bromine, which are easily volatilised and stain the test paper. The suggestions for fixing the sulphuretted hydrogen before it reaches the test paper, by means of filter paper or cotton-wool soaked in lead subacetate solution, while very excellent, fall short of that certainty which one desires to attain when dealing with a substance so poisonous as arsenic; there is a doubt as to whether the whole of the gas has actually come into contact with the lead solution. There has also been a fear in my own mind lest the lead solution should arrest the arsenic. In order to settle this doubt I have made numerous experiments by passing arseniuretted hydrogen through a 5 per cent. solution of normal lead acetate, with the result that I am satisfied that there is no abstraction of arsenium from the gas. This led me to make use of such a solution for the arrest of the sulphuretted hydrogen in the carrying out of



Sketch of apparatus. Bulbs 1, 2, and 3 contain the lead solution. Bulb 2 is behind the flask.

Gutzeit's test. After subjecting the process to a series of severe experiments I find that I can use it with the greatest confidence providing that the lead acetate solution is distributed in three vessels so as to give an idea of the efficiency with which it is doing its work. I have therefore devised the apparatus as shown in the accompanying illustration. The gas is generated in the flask and traverses five bulbs, of which the three middle ones, 1, 2, 3, are half filled with 5 per cent. solution normal lead acetate; finally it reaches the small thistle head, covered with a filter paper cap bearing a dried drop of mercuric chloride solution (1 in 20). The arsenical liquid is mixed with from five cubic centimetres to 10 cubic centimetres of the purest re-distilled hydrochloric acid, and the volume is adjusted to a fixed quantity, say 40 cubic centimetres in a 150 cubic centimetre flask. When the bulbs have been charged with the lead

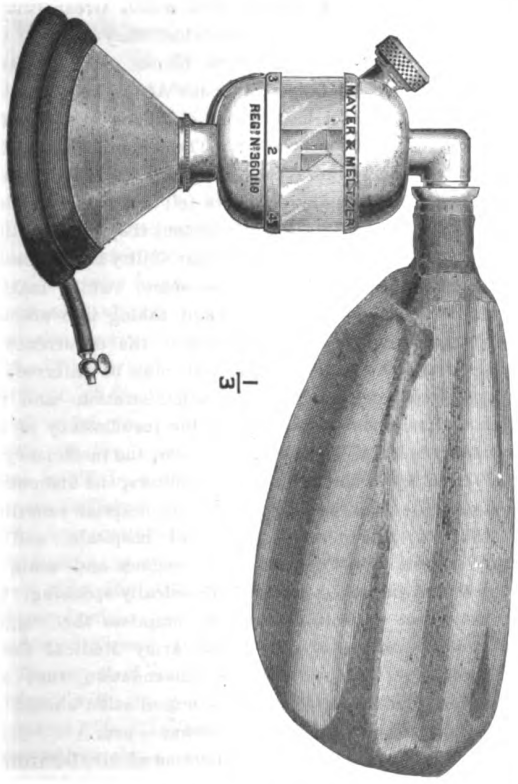
acetate solution and the test paper has been fixed in position a piece of rod zinc of definite size—say 15 millimetres by five millimetres—is introduced and the apparatus is put on one side for a greater or less time at the discretion of the analyst The third bulb containing the lead solution should not give signs of having its efficiency exhausted at the expiration of the test; this can be ascertained by comparison with the two preceding bulbs in which there will be, if sulphuretted hydrogen is present in the gas, a precipitate of lead sulphide.

For the purpose of making comparative estimations of minute quantities of arsenic it is imperative that the apparatus should be used of a standard size. Messrs. Baird and Tatlock are now making this apparatus of a uniform size and with a flask having a capacity of 150 cubic centimetres.

WILLIAM KIRKBY, F.L.S.,
Lecturer on Pharmacognosy, Owens College, Manchester.

A MODIFIED CLOVER'S INHALER.

THE accompanying illustration shows a modified form of Clover's inhaler made to my design by Messrs. Mayer and Meltzer, the chief points of which are as follows. The ether chamber is formed of a glass cylinder three inches in diameter, closed at either end by a light metal dome; this allows the operator to see the quantity of ether there at any time during administration. Ether need not be measured before being poured into the inhaler, as the inside of the lower dome is graduated and marked from half an ounce to



two ounces. The hot-water jacket, so very seldom used, is dispensed with, as if, owing to cold, the ether evaporation should be slow, it can always be quickened by the warmth of the hand round the ether chamber. The weight of the ether chamber is eight ounces as against 11½ ounces in the ordinary Clover inhaler and 16½ ounces in the Rumboll inhaler—an acceptable difference in a long operation.

FRANK H. ROSE, M.R.C.S. Eng., L.R.C.P. Lond.,
Anæsthetist to the Bristol Royal Hospital for Sick Children and Women.
Bristol.

THE BUILDINGS OF THE NEW ROYAL INFIRMARY AT GLASGOW.

THE following is the text of an open letter from the Glasgow Institute of Architects referred to in our leading columns and in our Glasgow correspondent's letter:—

To the Chairman and Managers of the Glasgow Royal Infirmary.

GENTLEMEN,—Recognising it to be your earnest desire that the infirmary when reconstructed should conform to the most modern standards of design in this class of building, and that the subscribers and the general public have a right to expect this, we, the Glasgow Institute of Architects, as a body of technical experts in such matters, feel it to be our duty to state that, in our opinion, this result will not be achieved if the reconstruction is proceeded with according to the plans selected by your sub-committee in the recent competition.

We attribute this failure, not to any lack of zeal on the part of your committee, or of ability on the part of the competing architects, but mainly to the manner in which the competition was initiated and carried through, and that in the following respects among others:—

1. That along with the printed conditions provided for the competition there were issued two sets of sketch plans as indicative of alternative arrangements which the sub-committee recommended, and which were stated in the accompanying report to be drawn by or under the direction of two members of the sub-committee respectively.

2. That a Jubilee Block to be situated on a particular part of the site was insisted upon as an integral part of the scheme.

The results of these elements in the conditions were:—

(*a*) That the competitors and the assessor were hampered in the exercise of their individual judgment as to the main points of importance in such a building—viz., the distribution of the various buildings with respect to each other for convenience of working and of all for the freest access of sun and air.

(*b*) That the competitors were placed in the invidious position that, in the event of the schemes recommended by the committee not proving themselves to be in accord with their judgment and experience, they were bound, in departing from them, to meet with disfavour from those influential members of the committee who would enter upon the examination of all the plans with minds necessarily biased in favour of those which they themselves had put forward, while reserving their position as judges.

(*c*) That as the result, the proposal that Plan E be accepted, which became the finding of the meeting, was moved by the gentleman who was actually the author of the scheme which was adopted and worked out in detail by this competitor.

3. That neither of the sketch plans issued are in accord with the present-day principles of hospital design, as might indeed be expected, seeing that their authors have not enjoyed the training which would qualify them as surgical, medical, or architectural experts; that, in fact, the plans are in many vital particulars inadequate and out-of-date, and that these faults are naturally displayed equally in the selected design, which is but an elaboration of one of them. A corroboration of this assertion with regard to the radical faultiness of the plans in question is furnished by the fact that six out of the 10 competing architects found it necessary, in spite of risk of possible consequences already alluded to, to entirely throw over the schemes furnished to them, and that among this number are found all the four architects from outside of Glasgow (two from London and two from Edinburgh), who were presumably invited specially on account of their knowledge of hospital design.

Such being the opinion of the institute after a very mature and careful consideration of the whole subject, we would most earnestly urge the managers, before committing themselves and the public to the erection of any portion of the building, as designed, to have the plans submitted to one or more independent hospital authorities of recognised and outstanding position for consideration and report.

Apart from the all-important question of the erection with the public funds of an entirely adequate and modern hospital, we, the Institute of Architects, feel it necessary to lodge a protest against the setting aside by the sub-committee, without any reason given, of the award of the professional assessor, Dr. Rowand Anderson—the more so that a simple majority of one was considered sufficient to overturn his judgment—as liable to prejudice the success, alike for promoters and architects, of future competitions in Glasgow. And we have further to state, that the erection of a Jubilee Block, such as is proposed, seven storeys high, and in the position selected, will, if proceeded with, dwarf and irretrievably injure for all time the external appearance of the Cathedral. The foregoing statements represent the unanimous finding of the Glasgow Institute of Architects, at a meeting specially called to consider a report of the council on the question, and as the matter is not only one of the greatest public importance but of extreme urgency, owing to the proposal of your sub-committee to proceed at once with the erection of the Northern Block, it has been communicated to the public press at the same time as it is submitted, with our earnest prayer for its consideration, to yourselves.

In name and on behalf of the Glasgow Institute of Architects,
C. J. MACLEAN, Secretary.

115, St. Vincent-street, Glasgow, Jan. 21st, 1901.

PRESENTATION.—At the Public Offices, Pentre, on Jan. 23rd, in the presence of a large gathering, Mr. Herbert Jones, L.R.C.S., L.A.H. Irel., D.P.H. Cantab., L.S.A., and Mrs. Jones were presented with a writing desk, a revolving chair, a case of silver knives and forks, a silver tea-tray and tea service, spoons and tureen, with a framed photograph of the officials of the Rhondda Urban District Council, as a mark of respect and esteem upon the occasion of Mr. Jones resigning the appointment of medical officer of health of the Rhondda Urban District.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 2, 1901.

The Royal Commission on South African Hospitals.

THE Report of the Royal Commission on the care and treatment of the sick and wounded during the South African campaign was published last week. It made its appearance at a time of deep gloom, when the most august and best beloved personage in the land—"the symbol of the unity of the British Empire," as Mr. BALFOUR truly said—was passing away. As might have been expected the report attracted little attention under such circumstances; but it is a very important public document about which we are bound to hear a good deal in the future. The subject has been taken up, though it can scarcely be said to have been yet discussed, by the daily press; yet so many excellent analyses of the report have appeared that we may fairly assume our readers to be substantially acquainted with its purport and scope. We do not here attempt to do more than deal with the report in a general way, reserving further and more detailed consideration for the immediate future.

The report consists of 71 folio pages and is signed by all the five Commissioners, and the impression that we have derived from our perusal of it is that it is able, comprehensive, and eminently fair. The minutes of evidence and appendix are published separately. The Commissioners have, as might have been expected from their position and reputation, conducted their investigations with great care and ability and, it need scarcely be said, in a perfectly impartial spirit. Their honest desire has been, as it seems to us, not only to collect all the evidence they could but to sift it in order to disentangle facts from fiction (and by fiction we mean all statements of an exaggerated kind having their origin in sentiment or self-interest) and to separate the relevant from the irrelevant. In this task they had the benefit of the legal guidance of their President, Sir ROBERT ROMER, one of the Lords Justices of the Court of Appeal. The Commissioners have, we think, succeeded in following the injunctions of OTHELLO: they have spoken of things as they are; nothing extenuating, nor setting down aught in malice. The constitution of the Commission would have been improved if some independent and experienced medical officer well acquainted with the regulations, practices, and military requirements of the service, who need not, of course, have been on the active list, had been appointed upon it, otherwise they seem to have shown themselves, as a body, capable of dealing with all the matter brought before them. It was particularly fortunate, seeing the important factor which transport played in the inquiry, that the general manager of a leading railway, Mr. FREDERICK HARRISON, was made a member of the Commission. We from the first suggested that some one having this technical knowledge should be appointed, for we knew the direction that much of the inquiry must take.

Briefly and summarily stated, what does the report amount to? The Commissioners record their judgment that, reviewing the campaign as a whole, it cannot be said that the medical or hospital arrangements have broken down or that there has been any scandal in the treatment of the sick and wounded, or any general or widespread neglect in regard to them and their requirements. They had to take count of and recognise the extreme difficulties connected with transport and military exigencies, although they do not admit that these, or the sudden influx of patients, were sufficient in themselves to account altogether for the state in which Nos. 8 and 9 of the military hospitals at Bloemfontein were in May, 1900. Taking the medical officers as a whole, the Commissioners find their conduct and capacity to deserve great praise. They extol their devotion and the unselfish way in which they have attended to the sick and wounded, often at the risk of life. Notwithstanding that the Royal Army Medical Corps, like any other large body of men, has its unfit or bad members, the Commissioners state that the proportion which these bear to the whole is very small. While finding that the medical staff and equipment were quite insufficient for such a war as that which Great Britain undertook against the Boer republics, they exempt the Director-General and his staff from blame, and as regards the Principal Medical Officer in South Africa and his staff they are declared to have done excellent and devoted work. The Commissioners add: "The organisation of the field and stationary and base hospitals for the colonial troops, the militia, and volunteers fell upon the medical staff in South Africa, and in our judgment they met the difficulties presented to them with singular ability and success." On the other hand, the Commissioners, while making many allowances for individuals and taking into account the difficulties of the campaign, admit the occurrence of mistakes—and in some instances, it may be inferred, of want of proper organisation and administration—and the existence of serious defects, such as the insufficiency of the Royal Army Medical Corps before the war, the inefficiency of a small minority of the army medical officers, the dishonesty and inadequate training of some of the hospital orderlies, the want of more nurses for fixed hospitals, and of sanitary officers and of ambulance wagons and tents of the latest and improved pattern. Practically speaking, the most important part of the report comprises the suggestions for the reform of the Royal Army Medical Corps and medical service and the recommendation that the constitution of this service and its organisation should be made the subject of inquiry when the war is over.

We said at the time of the publication of Mr. BURDETT-COUTTS'S letters in the *Times* that even if the substantial accuracy of his statements regarding the deplorable state of things at Bloemfontein and Kroonstadt were taken for granted, his deliberate allegation was a terrible one that the occurrences arose from causes which might have been foreseen, and which were, therefore, preventable. We believed, on the contrary, that the sudden and wholesale outbreak of enteric fever and the occurrences after Paardeberg, together

with the state of the hospitals, were in all probability mainly attributable to the exigencies of war and the deficiencies of transport—notably to the latter. The army had in fact outmarched its supplies. We find certain corroboration of that view in the report before us. The military history of the situation and the condition of the hospital arrangements at Bloemfontein are dealt with at some length, and the Commissioners declare, "the extent, suddenness, and virulence of the epidemic of enteric fever which occurred in the army at Bloemfontein could not, in our opinion, have been foreseen." The various plans of campaign, the rapid marches of the troops, and the capture and occupation of positions are matters of military concern. The fighting force had in any case to be supplied with rations and ammunition in order to protect themselves and the sick against attack and possible disaster. All this was, however, for purely military consideration, and the responsibility must, and quite rightly, rest with the general in supreme command. We have throughout our numerous articles upon the South African war laid great stress upon the fact that transport is nearly always *the* difficulty in war, and upon page after page the difficulty of transport is in some shape or other referred to, while the broad fact stands out that so long as the army was fighting its battles in the vicinity of available railway transport things went well with the medical arrangements.

When war became inevitable neither the nation, the Government, nor the military authorities had any idea of the formidable nature of the task before them. They did not then know of the extent of territory which was to become the theatre of war, of the fight with physical geography that was before us, nor did they realise that the enemy were armed with the latest weapons and were capable of adopting an altogether new system of tactics. The army does not exist for its medical service, but the medical service for the army. In any designed military scheme the medical requirements have to occupy a proportionate place. The army corps originally sent out to South Africa at the time of their going out more than exhausted the available strength of the Royal Army Medical Corps in this country. That corps was already undermanned calculated on the basis of the small force which it was considered at first would be necessary for the subjection of the Boers. It was entirely inadequate to the needs of the much larger army eventually despatched. The campaign in South Africa has been a unique experience in warfare. It has taught us more than any other war, perhaps, the primary importance of preparedness—of having a medical system, organisation, and service based upon a broad and comprehensive scheme.

The report of the Commissioners bristles with interesting points, with many of which, and particularly with those portions of it which contain practical suggestions and recommendations about military medical reorganisation and army hospital reforms, we shall deal hereafter in detail. We publish this week the suggestions made by the Commissioners for the remedying of certain defects in the Royal Army Medical Corps and think it fair in this connexion to remind our readers that Mr. BURDETT-COUTTS has disclaimed all intention of making reflections upon the *personnel* of the corps whose work he has described in his recent book as "magnificent and performed under superhuman difficulties which they never should have had to encounter."

The Buildings of the New Royal Infirmary at Glasgow.

WE have commented, not upon the design selected by the Jubilee Committee of the new buildings of the Glasgow Royal Infirmary, but upon the procedure of that committee. We need not again detail the unfortunate methods which the Jubilee Committee made use of in procuring designs for the new buildings and in making a choice therefrom, but we recur to the subject in the hope that a new policy will be adopted ere irremediable mischief is done. The committee appointed an expert assessor whose judgment they deliberately set aside, but this, it now appears, is not the only occasion when they have refused well-informed help. A letter was sent to the secretary of the Royal Infirmary so long ago as May 11th, 1899, signed by two medical men representing the medical and surgical staff of the infirmary, setting forth that the "tentative specification of general requirements" for the reconstruction of the infirmary, which had been submitted to the medical staff, was inadequate. The letter also expressed regret that "the representatives of the staff are not, as they had been led by their letter of invitation to suppose they would be, members of the advisory committee of the managers." The receipt of this letter was, so we are informed, never even acknowledged by the managers. Be that as it may, the advice of the medical men whose life-work is done within the walls of the infirmary was never sought or followed by the managers when entering upon the reconstruction of that infirmary.

A new feature has now been introduced into the controversy by reason of a communication sent by the Glasgow Institute of Architects to the chairman and managers of the Glasgow Royal Infirmary protesting against the reconstruction of the infirmary being proceeded with in accordance with the design selected by the Jubilee Committee. The Glasgow Institute of Architects, through their secretary, point out, firstly, that with the printed conditions for the competition two sketch plans were issued indicative of alternative arrangements recommended by the sub-committee, which plans were stated to be drawn by, or under the direction of, two members of the sub-committee respectively; and, secondly, that a Jubilee block was to form an integral part of the scheme. These conditions the Glasgow Institute of Architects consider to have hampered both the competitors and the assessor. The assessor was placed in the awkward position that he might have to find fault with a design exactly following the suggestions of the Jubilee Committee. The competitors, any and all of them, were tempted to sacrifice their convictions if they could not bring themselves to regard with favour the sketch plans of the Jubilee Committee. If it be correct, as the Glasgow Institute of Architects state, that the proposal to adopt the plan eventually was moved by the gentleman who was actually the author of the successful scheme, no criticism has as yet been passed that is severe enough to meet the circumstances. The

protest goes on to call attention to defects in the adopted design and concludes: "We would most earnestly urge the managers, before committing themselves and the public to the erection of any portion of the building as designed, to have the plans submitted to one or more independent hospital authorities of recognised and outstanding position for consideration and report." We echo the advice thus given to the managers and are sure that all who read the letter of protest of the Glasgow Institute of Architects, which will be found on p. 337 of this issue of THE LANCET, will do the same.

The plan for the reconstruction of the infirmary selected by the Jubilee Committee is by no means in accordance with the views of experts either from a medical or an architectural point of view. The essence of an infirmary is to be a place for the reception and proper treatment of the sick. Apparently, the plans selected by the committee do not fill these requirements in view of modern ideas on hygiene and sanitation, and the opinion of the medical officers of the infirmary has never been sought, so that the obvious way of avoiding trouble has not been taken. It is not too much, we think, to ask the Jubilee Committee and the managers of the Royal Infirmary to reconsider their position and to agree to the request of the Glasgow Institute of Architects to have the plans submitted to some independent authority. The new Royal Infirmary is not to be a temporary building; it is to be one of the permanent buildings of the city and to commemorate the long duration of the greatest reign in British history. If an inadequate building is erected money will be wasted, the treatment of the sick and needy of Glasgow will of necessity be inadequate, and the authorities, if so be that they persist in running counter to the advice of those who are most qualified to give an opinion, will incur, and rightly so, blame from their fellow citizens. The managers should pause before spending some quarter of a million of money and before entering upon what may be an irreparable mistake if they wish to be free from the charge of obstinacy which will inevitably be levelled against them if they persist in their present apparent attitude of being unwilling or unable to own that they have made a mistake.

Peripheral Neuritis of Arsenical and Alcoholic Origin.

THE recent epidemic outbreak of arsenical poisoning in beer-drinkers in the North of England and the Midland counties has given rise to many points of unusual interest. Some of these we have already referred to. In the paper which we have published by Dr. E. S. REYNOLDS[1] and which introduced a debate upon the epidemic at the Royal Medical and Chirurgical Society, a very minute description of the symptomatology of the outbreak will be found, together with some opportune remarks on "so-called alcoholic paralysis or neuritis." We have followed Dr. REYNOLDS'S example in placing the last phrase within inverted commas, for he remarks that for many years he has doubted whether ethylic alcohol *per se* does cause peripheral neuritis, and has felt more confirmed in this uncertainty each succeeding year. When the cases, therefore, in the recent epidemic became numerous he at once looked out for some other cause of the neuritis than alcohol. At first he could not find a satisfactory explanation, but he corroborated his previous idea that in the Manchester district alcoholic neuritis occurred only among beer-drinkers, not amongst pure spirit-drinkers. The occurrence of certain skin lesions, however, especially herpes zoster, speedily suggested arsenic as the cause of the neuritis and this was corroborated by chemical examination. Dr. REYNOLDS'S suggestion that ethylic alcohol is not capable of producing neuritis raises a point on which at present a definite opinion cannot be given. The etiology of "alcoholic neuritis" has not been so openly challenged before. It is worthy of note, however, that the views of various observers have undergone modification. At one time spirit-drinking was considered to be the commonest cause of "alcoholic paralysis," but, judging from observations made at the Manchester Royal Infirmary, it would seem that the disorder is quite as often brought on by excesses in beer. One of the principal distinctions between "alcoholic paralysis" on the one hand and "arsenical paralysis" on the other has been considered to be certain skin affections which have been recorded as characteristic of the latter. Dr. REYNOLDS draws attention to some of these, such as erythromelalgia, which was one of the commonest lesions in the recent outbreak; but, as we have already mentioned, it was the appearance of herpes zoster which gave Dr. REYNOLDS the key of the puzzle. When this lesion occurred without any other very definite symptoms he at first considered that he was dealing with "epidemic specific herpes," but when other signs of arsenic poisoning presented themselves the diagnosis was placed beyond doubt. Dr. REYNOLDS is further of opinion that arsenic causes herpes by a direct action on the posterior spinal ganglion, just as it acts directly on the motor and sensory nerve fibres. Dr. H. HEAD has suggested that arsenic is only a remote cause of herpes, inasmuch as it renders a person more liable to be attacked by specific herpes, but in reply to this Dr. REYNOLDS suggests that previous epidemics of so-called specific herpes may have really been due to arsenical poisoning. The various suggestions raised in Dr. REYNOLDS'S most interesting paper can only be answered by further clinical and chemical investigations.

In another paper, by Dr. ROBERT J. M. BUCHANAN,[2] attention is likewise drawn to the occurrence of herpes zoster and other skin lesions in cases of peripheral neuritis arising from drinking beer containing arsenic, and the characteristic pigmentation is also referred to. The series of cases Dr. BUCHANAN describes is an interesting one, and the connexion between the symptoms and the beer-drinking admits of no doubt. A further contribution to our knowledge of the subject has recently appeared in the shape of a book by Dr. T. N. KELYNACK, medical registrar of the Manchester Royal Infirmary, and Mr. WILLIAM KIRKBY, lecturer on Pharmacognosy in the Owens College, Manchester.[3] In connexion with our remarks on Dr. REYNOLDS'S paper it is interesting

[3] Arsenical Poisoning in Beer Drinkers, by T. N. Kelynack, M.D., M.R.C.P., Medical Registrar (late Pathologist), Manchester Royal Infirmary, and William Kirkby, F.L.S. 1901. London. Baillière, Tindall and Cox. Pp. 100. 16 Illustrations. Price 3s. 6d.

to note a passage in the introduction to this book, in which the authors make some comments on the nature of the alcoholic beverages which the patients confessed to having taken. Beer was almost invariably the drink to which the symptoms were ascribed—a few had confined themselvee to stout; but the important statement of the authors is that they were unable to meet with any evidence of arsenical poisoning in any persons who had limited themselves to the use of brandy or whisky. To this they add: "It is a remarkable fact that even in confirmed drinkers in this district [Manchester] who have restricted themselves, according to their own account, to spirit, peripheral neuritis is so rare that we are not prepared to substantiate a single case met with during recent years." After reading such statements as we have already referred to, all tending to throw doubt upon the power of alcohol to produce peripheral neuritis, it would be highly instructive if other observers would chronicle their experience. It seems rather a bold suggestion that arsenic has for a long period and generally existed in beer, without detection, in sufficient quantities to cause neuritis, yet that would seem to be implied. Dr. KELYNACK gives a good account of the symptoms encountered in the cases occurring in the recent epidemic, laying stress naturally on the manifestations in connexion with the cutaneous system and with the nervous system, the illustrations with regard to both classes being well chosen and executed. Pigmentation the author considers to constitute one of the most conspicuous and characteristic features, although it varies greatly both in intensity and extent, sometimes being so slight as to be readily overlooked, while in others it may be so deep and so general as to give to the patient the appearance of a mulatto. Dr. KELYNACK also states that in a number of cases which had been observed herpes developed as the earliest, and oftentimes the only definite, manifestation of arsenical poisoning.

Our knowledge of arsenical poisoning and of peripheral neuritis, especially in regard to its etiology, will yet receive great additions and the views hitherto held may be considerably changed; we therefore look forward with the greatest interest to the conclusions which will ultimately be arrived at, and towards these the contributions to which we have referred can only be considered as preliminary. The debate upon Dr. REYNOLDS'S important paper remains in abeyance at the Royal Medical and Chirurgical Society, but when it is resumed some interesting communications will be made. In the meantime fresh cases of arsenical poisoning are occasionally reported, though every precaution is now being taken by the purveyors of beer. The medical profession is everywhere alert to detect and record the symptoms, so that there is probability that some of the points in the story of epidemic poisoning by arsenic that are now confessedly obscure will ultimately be cleared up. It is possible also that the rôle played by arsenic in the production of certain of these cases of neuritis will be challenged. The small dose that is assumed to have caused fatal symptoms has been a difficulty in the minds of many observers, and the possibility of some other poisonous substance having found its way into beer has been widely recognised. In our columns this week (page 318) we print an interesting communication from Dr. F. W. TUNNICLIFFE and Dr. OTTO ROSENHEIM, F.C.S., who suggest the possibility of selenium being such a poisonous substance. Mr. VIPAN of Canterbury had previously called attention to the same possibility.

Annotations.

"Ne quid nimis."

THE COMMUNICATION CORD ON RAILWAY TRAINS.

FROM time to time some ghastly murder, or attempted murder, or outrage occurs in our railway trains, when the necessity of an efficient and easy means of communication between the passengers' compartment and the guard becomes emphasised. As long as our system of travelling on railways is not on the corridor principle it is certainly essential that the passengers should be protected by being able to communicate with other parts of the train. Recently a murder was committed on the London and South-Western Railway under circumstances that are too well known to need more than a few words of recapitulation. There were present in a third-class compartment three passengers—two men and a woman—all unknown to each other. The male passengers fell into conversation which resulted in one of them shooting the other with a revolver. The female passenger narrowly escaped with her life, receiving a bullet in her cheek. By pleading with the assailant she kept him quiet until the train drew up at Vauxhall, where he attempted to escape, but unsuccessfully. The lady's mind, it would appear, was too disturbed to allow her to think of pulling the bell communicating with the guard. It is probable that she did the best thing for herself and for the cause of justice by humouring the assassin. It is not likely that she would have been allowed unmolested to turn her back upon the murderer to pull the cord, which is certain to have been in some inaccessible place. There is not much confidence expressed by the travelling public in the means of communication commonly provided by the railway companies, and nobody can put them to the test without the risk of suffering a penalty. We do not suggest that the public should be free to try these means of communication merely out of curiosity. It must be admitted, however, that such a test would be the only good one and the only one that would give confidence, but, so far as we know, it is never applied. We think that the Board of Trade might easily have powers to test these means of communication in a practical way. Thus an inspector could be appointed whose duty it should be to travel on the various railway lines from time to time and use now and again these means of communication to see if they act in practice, and thus fulfil what is an essential requirement of travelling by the system of separate compartments. To some extent we are aware such practical inspection would be vexatious to the railway companies, but care could be taken to give the least trouble and the delay caused need not be serious. Of course, the inspector should be able to show that he had a right to pull up the train by virtue of his office under the Board of Trade. We believe that such an appointment would meet with the approval of the public. The result of the inspector's tour would be of interest. It is certain that he would fail to find any response on pulling the cord in many instances. There are the risks in the case of electric bells of the current failing and in the case of mechanical arrangements of neglect to connect the terminals. These things are due to the fact that it is not a matter of routine for the means of communication to be tested by the railway officials before a train starts on a long

journey. The appointment of a travelling inspector empowered by the Board of Trade to make surprise investigations would change this. Every railway company would be careful that such means of intercommunication as they provided were kept in regular efficiency. It would be the inspector's duty also to criticise the means of communication provided even when in working order. Some "cords" are so difficult to get at, or the directions given as to the proper way to pull them are so wordy, as to render them practically useless in an emergency. This would soon be altered.

THE ANNUAL REPORT OF THE LOCAL GOVERNMENT BOARD UPON THE METROPOLITAN WATER-SUPPLY.

MR. LONG, the President of the Local Government Board, having promised to bring in a Bill with regard to the metropolitan water-supply, will require all the assistance he can obtain from the Water Examiner appointed by the Local Government Board, if he is to obtain a grasp of the complicated matters with which he will have to deal. It is unfortunate that he will not have the help of the late Major-General Scott, whose long experience had made him perfectly familiar with all the details of the working of the metropolitan companies. There are, happily, on record some suggestions made by General Scott in regard to certain proposed new measures for the more efficient control of the companies and it may well be hoped that these suggestions will not be disregarded. Putting the matter briefly it was suggested by him that the supervising authority should have power to insist that proper works were made by the metropolitan companies to ensure that water abstracted from the Thames should undergo the necessary processes of sedimentation and filtration before it was supplied to the consumers. The Water Examiner should therefore supply the President of the Local Government Board with information on this point and it is advisable that he should be very careful as to the statements which he makes and also that his reports should be so clearly worded that there is no possible way of misunderstanding them or of reading into any part of them a meaning which the facts do not justify. It does not seem to us that the annual report of the Water Examiner for the years 1899–1900[1] quite carries out the ideal which we have suggested. For example, it may be remembered that Lord Balfour's Commission suggested that the water of the Thames while the river is in flood should not be used directly without proper treatment. The Commission pointed out that, for the purification of water, subsidence and filtration were necessary, that in their opinion the provisions which existed at the time of their inquiry were in the case of some companies quite inadequate, that regulations on these matters should be drawn up, and finally, that the enforcement of the regulations should be entrusted to the public Water Examiner. The present Water Examiner in his report says that the recommendations of Lord Balfour's Commission in regard to the capacity of reservoirs have borne fruit, and amongst others an example is cited of the East London Company's reservoirs at Walthamstow. Now it is, of course, perfectly true that at the present time the East London Company has enormous reservoirs in the valley of the Lee. It seems to be assumed by the Water Examiner that the great increase which has been made in the reservoir capacity is due to the recommendations of Lord Balfour's Commission, and that the reservoirs were made for the purpose of allowing sedimentation to take place and not for the purpose of storage. It was clearly to the interest of the East London Company from a financial point of view to have large reservoirs for storage of water in the valley of the Lee, and it necessarily happens that if dirty water be stored in reservoirs sedimentation takes place. It seems to us, however, that the report of the Water Examiner on this point infers, or might lead anyone who is not thoroughly acquainted with all the details of the works of the company to infer, that the directors of the company attach very great importance to the process of sedimentation; and that they have therefore made these enormous reservoirs for the prime purpose of water purification. We do not think that the facts quite point in this direction. Do the other arrangements of the company throw any light on the matter? At the present time the company is authorised to draw from the Thames 10,000,000 gallons of water daily. As a matter of fact, rather less than this amount is, we believe, taken. What is the reservoir capacity provided to receive this water? It does not exceed 5,000,000 gallons. Now the East London Company abstracts water from the Thames day after day whether the river be in flood or not, and yet the company has not provided sufficient reservoir capacity to store this water even for one single day. This fact alone clearly shows that the directors of the company do not attach the importance which they ought to the purification of flood water by sedimentation. We are quite aware that the present Water Examiner has not held his appointment for a prolonged period, but we think it is now quite time that he should make investigations, or cause investigations to be made, in regard to the purity of the water supplied from the Thames station of the East London Company, and that these investigations should be made with frequency during all periods of the year, and daily during periods when the river is in flood.

DEFECTIVE VISION IN BOARD SCHOOL CHILDREN.

IN November, 1899, the School Board for London decided that teachers should be requested to test the eyesight of the children by means of certain testing cards with which they would be supplied. A report upon the returns supplied has just been forwarded to us—it is dated July 25th, 1900—by the medical officer. From a note appended to the report by Sir Charles Elliott we learn that the test card was hung up on the wall and at a distance of 20 feet away from the wall a line was marked on the floor. If the child standing at this distance could read the bottom line of letters, D. = 6 metres, it was marked in column 1. If it could not read the bottom line but could read the next, D. = 9 metres, it was marked in column 2, and so on. If at 20 feet distance a child could only read the top letter, D. = 60 metres, it was marked in column 7. Of the full number of children tested—in all 338,920—259,523 were passed as having good distance vision, while 79,167 were given notices for their parents advising them that the children were suffering from "serious defective vision" and that they should be taken to see an oculist without delay. By far the largest percentage of defective vision was found in the City division, where only a little over half the children examined were found to have good sight. Other divisions where sight was below the average were Westminster, Hackney, Tower Hamlets, Finsbury, and Southwark. Those in which eyesight was above the average were Greenwich, East and West Lambeth, Chelsea, and Marylebone. In other words eyesight varied inversely to the density of houses, thus seeming to bear out Mr. Brudenell Carter's hypothesis of the vision of town-dwellers being weak owing to the eye having but little opportunity of being exercised in distant vision. Another corroboration of this hypothesis has lately been put forward in the remarks made about the superiority of vision enjoyed over our troops by the Boers. The ratio of good sight rises with the standard, but this, it is suggested, was due to increased reading power. On the whole, the

tests, although necessarily somewhat rough, appear to have been fairly accurate, for Dr. W. R. Smith mentions in the report that Mr. Ernest Clarke, F.R.C.S., of the Central London Ophthalmic Hospital, stated that of the children applying at the hospital only about one in 12 did not require glasses. On the other hand, Mr. R. J. Bland, the secretary of the Royal London Ophthalmic Hospital, stated that many children applied to the surgeons of that hospital whose eyesight was not defective. Sir Charles Elliott remarks that after all the results may be considered as approximately true and adds that at any rate they show which children should sit on the front benches when it is required that they should see what is drawn or written on the black-board. We see further that Dr. Smith recommends that the test should be applied to every child on admission—a recommendation which we hope has been carried out.

A MEMORIAL TO THE LATE SIR RICHARD THORNE.

A TOUCHING tribute has been paid by the medical department of the Local Government Board to the memory of their late distinguished chief. The memorial, of which we reproduce a copy, has recently been placed in the church of St. John's, Woking, where Sir Richard Thorne was wont to worship when at Woking and in the churchyard of which his remains are laid. The tablet, which is made of gun-metal and mounted on an oak base, was artistically designed

by Mr. Kitchin, the assistant architect of the Local Government Board, and executed by Messrs. T. Elsley, Limited, of Titchfield-street, W. The inscription is of a simple nature and merely places upon record the regard in which the medical staff held their chief. The great work which was done for the public health and for the nation by Sir Richard Thorne finds its fitting recognition in a continued application in practice of the results of his labours. The influence which he exerted in raising the dignity of the public health service and procuring for medical officers of health throughout the country a better status and a more useful public position is not as yet quite adequately recognised, but it will doubtless be appreciated in full by the future chronicler of public health progress during the later years of the Victorian era.

STREET RUFFIANISM.

THE Hooligan question is still with us and is being debated in the columns of the daily press and of the monthly magazines. In the recently published February number of the *Pall Mall Magazine* Mr. Arthur Morrison, who has a wide acquaintance with the genus, gives us his impressions. We are glad to see that he agrees with what we have insisted upon over and over again in THE LANCET—namely, that imprisonment and fines are neither troublesome nor expensive to the Hooligan. The former he rather likes than otherwise, and the latter are paid by a "whip round." Mr. Morrison argues that the lash is the only real deterrent of Hooliganism. We are quite in accordance with those who say that the prevention of Hooliganism must be sought by catching the budding rough young and giving him some healthy employment and some amusement. The youth of the upper class or the middle class, especially he who shows a disposition to be troublesome at home, is, mercifully for himself, sent to a public school. Here he either learns to behave himself or, if he is not willing to learn, he is taught by the application, it may be, of a racquet, that he must do as he is told whether he likes it or not. But the class from which Hooligans are recruited never learn to obey and it is not altogether their fault that they turn out as they do. By all means, then, let us provide early discipline for the Hooligan infant, but the full-grown article must be made to obey by the lash. While on this matter we may refer to an admirable letter by the Rev. C. G. Lang published in the *Times* of Jan. 21st. In this letter he recounts the case of four boys, aged about 15 years, who, as boys will do, engaged in feudal fights with the boys of another street. In the course of the fight two boys were shot with slugs from a toy pistol. For this offence the boys were sentenced by the Recorder to five days' imprisonment and three years in a reformatory. When they come out what will become of them? They will have herded with criminals and will only too probably be contaminated for life. These are the cases where a legal birching would do all the good in the world.

THE WITNESS OF THE SKIAGRAM.

AT the meeting of the Bradford Medico-Chirurgical Society, held on Jan. 15th, a report of which will be found in another column, Dr. J. B. Hall read a paper upon the Medico-Legal Aspects of Skiagraphy in the course of which he said that in the hands of unscrupulous persons a skiagram was a dangerous weapon. An expert, he said, possessed of good anatomical knowledge could produce in a skiagram almost any degree of deformity he chose. The public had come to believe that a skiagram was a representation analogous to a photograph showing only what existed and nothing more. We must add that if the public believes that an ordinary photograph always shows only what exists it is grievously mistaken. An ordinary photograph can be "faked" to any extent, and even with no intention to deceive will give most bizarre results. A photograph of a building may be obtained which is twice as wide at the bottom as at the top, or *vice versâ*. A man may appear to have feet about a yard long and a head no bigger than a turnip. Everything depends upon the way in which the photograph is taken. So with the skiagram: the distance of the tube from the body, the angle at which the kathode is inclined to the plate, and many other details have to be taken into account. But we scarcely think that Dr. Hall is right in saying that

any degree of deformity can be produced. There would be no difficulty in producing the appearance of a supposititious bullet or needle in the body, or even by manipulation of the negative to produce a print of an apparent fracture, but that deformities, strictly so called, could be produced by unfair means we take leave to doubt, especially if the use of an accurate localiser is insisted upon. Nevertheless, Dr. Hall's paper contains a useful warning against belief in skiagrams taken by non-experts, for these certainly may be deceptive.

RADICAL CURE OF HERNIA

HOWEVER satisfactory some of the results may be which are obtained by the methods of radical cure for hernia which are now in use it cannot be denied that these methods are by no means perfect. In this number of THE LANCET we print descriptions of two new methods—one for the radical treatment of femoral hernia and the other for inguinal hernia. The former is contained in a clinical lecture by Mr. W. H. Battle and the method consists in bringing down a portion of the aponeurosis of the external oblique muscle and placing it as a shutter over the upper end of the crural canal, suturing it to the fascia over the pectineus and to Gimbernat's ligament. Additional sutures are used to hold the displaced aponeurosis in its new position. This method has proved valuable in several cases under Mr. Battle's care and is well worthy of more extended trial. The operation for inguinal hernia is one which has been practised for some time by Mr. H. P. Symonds of Oxford. By means of an incision above the external abdominal ring the peritoneal cavity is opened, and from within, with the help of a pair of volsellum forceps, the hernial sac is inverted and is then twisted and stitched to the cut edge of the peritoneum; then the wound is closed, the pillars of the external ring being also drawn together with sutures. The procedure is decidedly ingenious, but its true value can only be determined by further trial.

INFECTIOUS DISEASE IN EGYPT.

IN Mohamedan countries infectious diseases are seldom interfered with, being allowed to run their courses freely without any attempt to check or to control their ravages. In a case here or there some little effort may be made to ameliorate the condition of individual sufferers, but measures calculated to prevent or even to limit the dissemination of the infection are never adopted. As an excuse for such grossly culpable negligence it is averred by adherents of Islamism that resistance against the Divine will would be an impious procedure. They contend that since disease is an instrument of punishment in the hand of the Almighty their duty lies in a blind submission to the chastening, but that their contention is the outcome of sheer ignorance is plainly shown by the following extract from a decree issued by Mohammed Ali the Great, the first independent ruler of Egypt. Writing to Zeki Effendi, his Wakil at Alexandria, on the 12th Chawal, 1250 (Feb. 11th, 1835), the founder of the present dynasty says:—

"The aversion of the inhabitants of Alexandria to sanitary measures arises from their ignorance. ..... The plague—may God preserve us from it!—being the scourge of the deity, to flee the divine wrath in order to take refuge in his mercy is in no wise contrary to the holy law. Inasmuch as the condition of things now prevalent is a danger to mankind, in trying to escape therefrom one does not disobey the orders set forth in the divine book. Did not God, by the mouth of his prophet, say, 'Flee from my wrath as you would flee from the presence of a lion'? Is not this injunction applicable in the case of infection? If it should be wished I can call upon the doctors of canonical law to issue precepts (*fetwa*) to that effect. In a word, if it should be necessary to collect the whole of the prophet's prescriptions regarding the precautions to be taken against evil the result would be a volume of immense size. The people who, through blind adherence to vulgar error, would deliver over a great city like Alexandria to the tender mercies of a pestilence are brute beasts and not human beings. The fleet, the hospitals, and the arsenal by a due observance of sanitary rules have succeeded, thanks to the Almighty, in protecting themselves from the reigning evil. Is not this a sufficient proof of the efficacy of sanitation?"

Under Mohammed Ali and Clot Bey the public health of Egypt was well supervised, but unfortunately their successors were not equally enlightened and soon nothing but the dry bones of the sanitary organisation remained. Corruption and inefficiency became paramount, and it was not until 1884, when an English sub-director was added to the Services Sanitaires, that any improvement took place. Since then there has been a systematic attempt to deal with outbreaks of infectious disease, and considering the insufficiency of the funds at the disposal of the sanitary authorities the results may be said to have been satisfactory. According to a somewhat elaborate return which has lately been published the Egyptian infectious disease record for the 10 years 1886–95 may be briefly shown in tabular form as follows:—

Decennial Period 1886–1895: Total Number of Deaths.

—	Natives.	Foreigners.
Small-pox	2,988	444
Typhic fevers	12,143	823

Decennial Period 1886–1895: Numbers treated in Hospitals and Ambulances.

—	Admitted.	Died.
Small-pox	8,250	1,791
Typhic fevers	10,963	1,974

The generic term *typhic* includes the following diseases: enteric fever, exanthematic typhus, relapsing fever, and bilious fever. At first the ambulances dealt with only a small proportion of the cases, but towards the end their operation was extended. The above figures do not include the returns from the Frontier Province which is under military control.

A SCHEME FOR RESEARCH WORK IN MENTAL PATHOLOGY IN THE UNITED STATES.

A COMMITTEE of the New York Neurological Society, with Dr. Frederick Peterson as President, was recently appointed by the President of the New York Commission in Lunacy "to offer suggestions as to a scheme of scientific study of mental diseases in connexion with the State's hospitals for the insane," and its report has now appeared. The signatories include well-known names in neurological and psychological medicine such as Dr. Frederick Peterson, Dr. B. Sachs, Professor Charles Dana, Professor Graeme Hammond, Dr. Joseph Collis, Professor Allen Starr, and others, and their recommendations are appended as follows:—

"1. It is to the interests of the State that original research work should be carried on in relation to insanity in order that the science should be advanced and better methods of prevention, treatment, and cure discovered.

2. There should be one central laboratory in the State, wherein the energies of the best scientific men in the various departments of medicine relating to insanity should be devoted wholly to the prosecution of original research.

3. Such a laboratory, combining the labours of well-qualified workers in general pathology, neuro-pathology, psychology, chemistry, and anthropology, should be able to produce from year to year results invaluable in advancing

the knowledge of the treatment and cure of mental disorders."

4. Recommendation 4 refers to the need of having a special medical officer to conduct the necropsies at every local asylum.

"5. The central laboratory should be freely open to any qualified scientific man for the prosecution of original research work under the direction of the laboratory experts.

6. The central laboratory should be part of a reception hospital for the insane situated at Manhattan Island."

These propositions accord in the main with the views entertained in Great Britain by many leading alienists and neurologists, and which have resulted in the establishment of the London County Council's Pathological Research Laboratory at Claybury so long back as 1895.

"DOCTORS" IN THE DOCK.

IT is a pity that the general press should not be more precise in their application of generic terms. Of course every intelligent reader of the newspapers knows perfectly well that a man charged with a misdemeanour and described in the paper as a "doctor" has, as a rule, no more connexion with the profession of medicine than has a Salvation Army captain with the British Army. Still, many readers of newspapers are not intelligent, and there is no doubt that the constant degradation of a title in the press does a certain amount of harm to an honourable profession. A most flagrant abuse of the term "doctor" is made only too often. In a recent instance it was applied in the headline of several newspapers to a man who in the account of the police-court proceedings was "described as a chemist," and who was prosecuted for supplying an abortifacient. It is open, of course, to any scoundrel who thinks to veil his misbehaviour to describe himself as "a doctor," and similarly medical students and actresses suffer commonly from vicarious vice, but that is no reason why a newspaper should calmly label him according to his preposterous claim. We beg our lay contemporaries to listen to our complaint, for we are giving voice to a real grievance of the medical profession.

ACTION OF MUCUS ON THE ORGANISM.

MUCUS is generally regarded as a harmless material, though if formed in superabundance in the air-passages it may become troublesome by inducing cough or by interfering with due interchange of gases in respiration. The important rôle now assigned to auto-infection has led M. Charrin and M. Moussu to investigate the effects of the introduction of mucus into the various media of the organism. The results which they obtained have proved unexpected and they have embodied them in a paper read before the French Académie des Sciences on Jan. 21st. To obtain mucus in sufficient quantity for the purpose of experiment and in a state of relative purity they scraped lightly the surface of the trachea and larger bronchi of horses, oxen, and large dogs. The material collected was agitated for about a quarter of an hour with water containing 8 per cent. of common salt, or with about a thousandth of its weight of sodium carbonate. The mixture was filtered and from 0·05 to 0·15 gramme of it per kilogramme weight of the body was injected into the marginal vein of the ear of a rabbit; death usually ensued in the course of a minute or two, sometimes preceded by slight convulsions, nystagmus, or slight dyspnœa. When the chest was immediately opened the heart continued to beat somewhat less strongly than in other forms of death and clots rapidly formed in the right ventricle. If the clotting were prevented by the injection of leech extract death did not occur. M. Charrin and M. Moussu were hence led to conclude that vascular obstructions were produced in the nerve centres and especially in the bulb, where thromboses were found, or possibly to emboli in different regions. The question then arose, What is the nature of this coagulating principle? The notion of the presence of a fibrin ferment suggested itself; but this view is not very tenable on the ground that fibrin ferment is easily destroyed by heat, whilst the coagulating power of mucus, especially when diluted with a weak solution of sodium carbonate, is retained even when exposed for several minutes to a temperature of boiling water. Also precipitation by alcohol, by means of which fibrin ferment is prepared, alters materially the action of mucus. It may be remarked that the dilutions of mucus are poor in leucocytes, and even when these are separated by the centrifuge the part which is freed from the leucocytes is as active in producing coagulation as that part where they have accumulated. Moreover, the coagulating substance does not dialyse or dialyses very imperfectly and slowly; it is precipitated by ammonium sulphate; and it is rendered inoperative by certain acids. The liver does not sensibly alter its properties, though coagulation seems to take place with great rapidity in the porto-hepatic region. The addition of a few drops of the dilutions of mucus to the blood of a horse *in vitro* causes coagulation to set in in the course of from two to four minutes, though such blood will often remain fluid for 20 minutes. Experiments made with mucus and obtained from other sources, as from the bladder and the surface of the intestine, have appeared to these observers to exert a similar coagulating action on the blood, and they propose to continue and to vary their experiments.

TYPHOID FEVER IN BELFAST.

DR. JOHN BARRON, who is a town councillor of Belfast as well as a medical practitioner, has forwarded to us a report of an interview granted by himself to a representative of the *Belfast Evening Telegraph* of June 23rd, 1900, on the subject of the prevalence of typhoid fever in Belfast. Dr. Barron does not consider that either the water or the milk is at fault in the main, though, of course, either may be contaminated accidentally. His view is as follows: "Typhoid fever is being engendered during the wet seasons of the year by the permeation of the soil with sewage matter and excreta entering it through the defective pavement of yards and passages and by leakage in sewers." In the hot weather, he says, this sewage-polluted soil becomes converted into dust which is blown about, carrying infection everywhere. What is wanted is careful protection of the ground in yards, passages, privies, ashpits, and the like, while the sewers should be kept in perfect condition so as to avoid leakage. Dr. Barron, however, believes that dry earth-closets would be safer, because sewers are almost sure to leak. In a speech before the City Council on August 1st, 1900, Dr. Barron advocated constant flushing of yards and passages and that the sewerage system should be improved. We have already dwelt upon the scandalous state of matters as regards sanitary conditions which characterised Belfast in the reports of our Special Commissioner,[1] who, as a result of his investigations during 1898, revealed an appalling state of matters with regard to bad drainage, while the Commission of the previous year showed the existence of 20,000 houses having no back passages and in which it was necessary to carry the contents of privies and ashpits through the living rooms. Although we cannot agree with Dr. Barron's theory in its entirety yet the pollution of the soil doubtless prepares the way for contamination of water, which probably occurs more generally than Dr. Barron appears to think, and we

[1] THE LANCET, Dec. 11th (p. 1559), 18th (p. 1623), and 25th (p. 1695), 1897; and Nov. 19th (p. 1359) and 26th (p. 1463), and Dec. 10th (p. 1584), 17th (p. 1667), 24th (p. 1737), and 31st (p. 1812), 1898.

certainly cannot allow that efficient sewerage is impossible. Apparently Dr. Barron does not think so either, for, despite what he is reported to have said in the interview, he recommended improving the sewerage in his speech before the Council. Dust, as we have recently been forcibly reminded by events in South Africa, is a potent cause of typhoid infection, and it is not impossible, given a polluted soil such as exists in Belfast, that infection is spread in this way. But we are still of opinion that a proper system of sewers and of strict building laws which shall be enforced without fear or favour would in a short time render Belfast a healthy city.

SOCIAL LEPROSY.

A CONTEMPORARY records with satisfaction the sentence of 12 months' imprisonment which has been passed upon "Ernest Cole" who when he was arrested was in female attire, by which device he more easily "accosted elderly intoxicated persons" previously to robbing them. This man who, as we are happy to believe is the case with most men of his class, is not an Englishman, was well known to detectives as an associate of blackmailers and was given by the police a character in round terms as "the most notorious character of Soho." We wish it were possible to believe that with the imprisonment of "Cole" the presence of these social lepers was banished from among us. Unhappily this is very far from being the case, and all unsavoury though such a subject is for discussion, it cannot be too widely known how infested is the jostling crowd of Piccadilly by night with men of the vilest kind, trading on the wages of prostitution and occasionally masquerading as women for purposes of fraud, blackmail, or bestiality. The young man exhilarated and thoughtless after dinner and a theatre, the elderly countryman, thinking no harm will result from a chance conversation—such persons fall victims to the wretches we are describing. One of the evils we suffer for our great general freedom is the presence in the midst of our capital of the scum thrown off from every great city of the continent. The vilest of the vile include these men of effeminate appearance dressed as women. Every Londoner should realise, as the medical profession is forced to realise, the fact of their existence, and if an occasion offers should help the police to effect their detection and arrest.

THE TREATMENT OF ASCITES IN CIRRHOSIS OF THE LIVER BY ESTABLISHING AN ANASTOMOTIC CIRCULATION.

THIS operation was first successfully performed in 1895 by Mr. Rutherford Morison. In 1889 Von der Meule performed it, but the patient died from shock; in 1891 Schelky followed and the patient died from peritonitis. In THE LANCET of May 27th, 1899, p. 1426, Mr. Morison published his fourth case which was successful. Two were uncomplicated and the patients recovered completely from the ascites. In the third case the diagnosis was doubtful, and in the remaining one the conditions were such as to preclude recovery. The *American Journal of the Medical Sciences* for December, 1900, contains an exhaustive paper by Dr. C. H. Frazier in which another successful case is published and all the previous cases are reviewed. Since Mr. Morison's first operation nine others have been recorded which, with the previous ones, make a total of 14. Excluding cases in which there was some error in the technique or the diagnosis or in which the operation was contra-indicated there remain eight cases. In these one patient was unimproved, one was improved, and six were living and free from ascites at periods after the operation of three, four, six, 24, 24, and 26 months respectively. The following is Dr. Frazier's case. A middle-aged man was admitted to hospital in May, 1900. He acquired syphilis in 1882 and had always taken alcohol freely. The heart was enlarged and a systolic murmur was heard over the whole præcordia. The liver could be felt below the costal margin and the spleen was enlarged. The abdomen was distended with fluid and the lower limbs were œdematous. The urine contained a trace of albumin but no casts. Diuretics were useless. Paracentesis was performed on May 30th and repeated four times at intervals of two weeks, when 512, 485, 330, and 400 ounces of fluid, respectively, were drawn off. On July 25th laparotomy was performed, the parietal peritoneum on either side of the incision was rubbed vigorously with a gauze pad, and the omentum, which was much thickened and contracted, was sutured to the parietal peritoneum and to the margins of the wound. The fluid was let out and the incision closed without drainage. Recovery followed. The patient was tapped on the thirteenth day after the operation and 328 ounces of fluid were withdrawn, and again on the thirty-sixth day, when only 96 ounces were obtained. Since that time—three months—there had been no re-accumulation of fluid and the patient had rapidly gained strength and was no longer bedridden. The operation purports to open a channel for the relief of the obstructed portal circulation by causing the formation of adhesions between the omentum and abdominal wall and between the surfaces of the liver and spleen and that of the diaphragm. That this is possible has been demonstrated post mortem. The technique is simple. A three-inch incision is made above the umbilicus in the median line or in the border of the rectus. The peritoneum of the adjacent surfaces of the diaphragm, liver, and spleen respectively, and the peritoneum on either side of the wound, are scarified with a blunt curette or rubbed with a gauze pad. The latter is the better procedure as it causes less bleeding. The omentum is sutured to the parietal peritoneum for a distance of three or four inches on either side of the wound and to the margins of the wound itself. The withdrawal of the fluid completes the operation. The wound is closed without drainage. The introduction of a drainage-tube is useless and increases the risk of peritonitis. One case in which the tube was used was fatal from this complication. It may be necessary, as in Dr. Frazier's case, to tap the patient during the time that the adhesions are forming. The dressing is secured by broad strips of plaster, which also keep the scarified surfaces in apposition. A special risk of the operation is the production of peculiar nervous symptoms which are supposed to be due to auto-intoxication from the direct entrance of the blood from the intestines into the general circulation without the intervention of the liver. Dr. D. Drummond of Newcastle has brought forward cases of cirrhosis of the liver in which such symptoms occurred. In one case the patient was on several occasions rescued from apparently hopeless coma by a brisk purgative.

AMBLYOPIA FROM INTOXICATION WITH JAMAICA GINGER.

IN the *Journal of the American Medical Association* of Jan. 5th Dr. E. Stieren has published a case of this condition, of which eight examples have been previously recorded in American ophthalmic literature. A man, aged 36 years, who was addicted to alcohol, drank heavily one Saturday. On Sunday, as he could obtain no liquor, he purchased a dozen ounce bottles of Jamaica ginger which he consumed before noon. He dropped into a drunken stupor and awoke about 3 P.M. totally blind. When seen by Dr. Stieren at 6 P.M. the pupils were dilated and did not respond either to light or accommodation. The fundi showed only slight blurring of the discs. The patient could see a hand moved at 12 inches. The corneæ were almost insensitive to the touch

of a camel-hair brush. He was confined to a dark room and given during the night 20 grains of calomel and of jalap in divided doses and one-eighth of a grain of pilocarpine hypodermically twice. Active diuresis and catharsis were produced. Next morning he could count the fingers at 10 inches. On the fifth day his vision and pupil reactions were normal. The lesion in this condition is supposed to be toxic retrobulbar neuritis.

THE ILLNESS OF H.R.H. THE DUKE OF CORNWALL AND YORK.

His Royal Highness the Duke of Cornwall and York is suffering from German measles. This disease is not very common in adults, but although it gives rise to great discomfort it is, as a rule, not of a serious nature. His Royal Highness is progressing favourably.

THE LATE DR. ARCHIBALD HAMILTON JACOB.

IT has come to the knowledge of a few friends of the late Dr. A. H. Jacob that owing to a long-continued period of ill-health and other causes he has died leaving his wife and daughters insufficiently provided for. Dr. Jacob, as Irish Editor of the *Medical Press and Circular* devoted much of his time to the interests of his professional brethren and the advancement of their just claims. For over 30 years Dr. Jacob was one of the most earnest workers on the Council of the Irish Medical Association, and for the same period was connected with the Royal College of Surgeons in Ireland, and at the time of his death was senior member of the Council. For many years he was a fearless and able advocate of the rights of the Poor-law medical practitioners of Ireland in the effort to obtain for them an adequate salary, security of tenure, and a pension in old age. A committee has been formed for the purpose of collecting subscriptions for the "Jacob Memorial Fund," to which the medical profession is earnestly requested to contribute. The committee in a circular letter to the profession write as follows:—

> Dr. Jacob was an accomplished scholar and a vigorous writer, and grappled with his subject in a masterly and independent manner, and was so richly imbued with public spirit that when advocating a cause he believed to be right he absolutely ignored his own professional interest and his own personal welfare. Those for whom he did so much cannot soon forget him, and his memory will be long esteemed in medical and private circles in Ireland—not only for his eminent services but for his upright and kindly disposition. The profession and the public who believe that the late Dr. Jacob did much to mantain the honour and dignity of the profession by his voice and pen have now an opportunity of helping materially his widow and daughters in a way in which he himself was not permitted to do, owing to ill-health and an unselfish life-long service in the interests of the profession.

Cheques and postal orders should be made payable to the honorary treasurers, Sir Charles Cameron, C.B., 51, Pembroke-road, Dublin, and Mr. L. H. Ormsby, 92, Merrion-square, Dublin. The honorary secretary to the Memorial Fund is Mr. George F. Blake, Registrar of the Royal College of Surgeons in Ireland.

BUCCAL SPOTS IN THE DIAGNOSIS OF MEASLES.

IN another column we publish a paper by Dr. L. Falkener which draws attention to an important diagnostic point in connexion with measles. Certain spots, known as "Koplik's spots," have frequently been mentioned as of some value in cases of doubtful diagnosis. Dr. Falkener shows that Filatow has a prior claim to their discovery and consequently describes them under his name. Into this controversy we have no wish to enter. The conjunction of a name with any disease or symptom is open to objection and we should prefer to see some definite name ascribed to these spots, such as "buccal eruption," or some other suitable term. However, for the present we may adopt the words used by Dr. Falkener. He gives a good description of the appearance and site of the buccal spots and states the time at which they first appear. This would seem to be an important matter on which hitherto sufficient stress has not been laid. Several authorities are quoted to prove that the spots are seen from two to four days before the appearance of the characteristic rash, thus enabling a diagnosis to be made and precautions taken as regards the spread of the infection much earlier than would otherwise have been the case. Their occurrence seems to be very constant. Dr. Falkener found them in every one of the 76 cases on which his paper is based. Further, the buccal spots are easy of recognition and not easily mistaken for other conditions. Aphthous stomatitis Dr. Falkener considers the only great difficulty in differential diagnosis, but the aphthoæ are more readily erased with a spatula or the handle of a tea-spoon than are the spots. Aphthous patches also lack the red areola; some of them are often too big, thereby casting doubt on the others; they are usually too opaquely white for buccal spots; and ulceration is often present at their bases. During two and a half years' practice at a fever hospital Dr. Falkener has examined 3000 or 4000 cases of all kinds and has never found the spots except in cases of measles. In their presence, then, we have an important indication of measles even before the rash appears; and when the latter is not characteristic, so that a doubt arises as to whether the case may not be one of r theln, they serve to check the diagnosis. They have also proved useful aids to diagnosis in cases of measles when the severity of laryngitis has given rise to suspicion of diphtheria. Dr. Falkener refers to six such cases and in all diphtheria was proved to be absent. The writer of this paper has done good service in publishing his observations, and medical practitioners will be glad to have another diagnostic point to fall back upon in a typical and doubtful case of measles.

AT a specially summoned meeting of the Royal College of Physicians of Ireland held on Jan. 28th the following resolution was unanimously adopted:—

> The President and Fellows of the Royal College of Physicians of Ireland, in College Hall assembled, whilst expressing their condolence and deepest sympathy with His Majesty King Edward VII. upon the death of our beloved Queen Victoria, desire to assure His Majesty of their loyal devotion to him, of their earnest desire that his reign may be as illustrious and beneficent as that of the Great Sovereign whom he succeeds, and of their fervent hope that his life may long be spared to enable him to work for the good and amelioration of his people.

IN consequence of the death of the Queen the Hunterian dinner of the Royal College of Surgeons of England, which had been arranged for Feb. 14th, will not take place. The Hunterian oration will, however, be delivered by Mr. N. C. Macnamara, as already announced, at 4 P.M. on Feb. 14th. The College will be closed to-morrow, Feb. 2nd.

AT a special general meeting of the Royal Medical and Chirurgical Society, to be held at 20, Hanover-square on Tuesday next, Feb. 5th, at 5.30 P.M., and summoned for the purpose, the adoption of a loyal address to His Majesty King Edward VII. will be moved by Lord Lister and seconded by Sir William Selby Church, Bart., President of the Royal College of Physicians of London.

THE annual dinner of the West London Medico-Chirurgical Society, which was announced to take place on Feb. 13th, has been postponed until May 8th.

MR. J. B. STORY, M.B. Dub., F.R.C.S. Irel., has been appointed surgeon oculist to His Excellency the Lord Lieutenant of Ireland in the room of the late Dr. Archibald Jacob.

THE death is announced of Mr. Bowater John Vernon, F.R.C.S. Eng., the senior ophthalmic surgeon to St Bartholomew's Hospital. He was also ophthalmic surgeon to the

West London Hospital. We shall publish an extended notice of his career in a future issue.

THE annual dinner of the Guy's Hospital Dental Society, which was fixed for Feb. 9th at the Hotel Cecil, has, in consequence of the death of the Queen, been postponed until Saturday, March 23rd.

REFLECTIONS ON THERAPEUTICS.

BY HARRY CAMPBELL, M.D., B.S., F.R.C.P. LOND.,
PHYSICIAN TO THE NORTH-WEST LONDON HOSPITAL AND TO THE WEST END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM.

IV.[1]

RATIONALISM AND EMPIRICISM.

How far should the treatment adopted by the physician be empirical and how far rational? Let us first define these terms. Empirical treatment is that which is founded on experience and regarding the *modus operandi* of which we may be profoundly ignorant. The treatment of syphilis by mercury and iodide of potassium affords an instance. It has been discovered as the result of repeated trials of different drugs that these two are capable of greatly mitigating and even curing the disease. We therefore give them in syphilis because we have found by experience that they are useful. We do not yet know, and it really matters very little that we should know, how they do good, though we may shrewdly suspect that it is by germicidal action; and if one day such is found to be the case we shall then understand the rationale of the treatment, which thereafter may claim to be rational. As I shall presently argue, however, any strictly routine treatment, even though its rationale be well understood, is in a sense empirical, since while being hall-marked by experience it involves no special process of reasoning. Rational treatment, on the other hand, is treatment founded on reasoning, and the *modus operandi* of which must therefore to some extent be understood. It presupposes some knowledge of the pathology of the disease we are treating and of the ends for which we are striving, and the adoption of special means to achieve those ends.

The surgeon is in the fortunate position that his treatment is nearly always rational. He knows exactly what is required to be done, and he adopts definite and eminently rational means of doing it. He cuts out a tumour, removes a stone, amputates a limb, sets a bone, reduces a dislocation—always with a definite, reasoned-out end in view. The physician is not so fortunately circumstanced. Nevertheless he also is able to infuse a good deal of rationality into his treatment. Let me give an instance from my own experience. A stout, gouty man, aged 65 years, who had for years led an active life and been a hearty eater, retired from business. Having little to interest him outside his own home, he now spent most of his time indoors reading, but in spite of this entire change in his habits, he continued to eat and drink in exactly the same hearty way as before. After a while he developed, for the first time in his life, bronchitis, which beginning as an acute attack gradually assumed the chronic form. During the course of the next 18 months he saw several physicians, but he got steadily worse, grew thin and irritable, short of breath and tottering; he seemed, in fact, quite suddenly to become an old man. His physicians led him to understand that little could be done for him, that he was, in fact, old, that his complaint was the penalty of his years, that he must expect to have some infirmity at his time of life, and that all he could do was to make the best of it. Accordingly their treatment consisted essentially in giving expectorants; it was not a rational treatment, and consequently it failed. When I saw the patient I ascertained that he came of a remarkably long-lived stock, that he had led a regular and careful life, that the condition of his heart and arteries was satisfactory, that his kidneys were sound, and, what was remarkable in one of his years, that his chest expansion was good. Upon these facts I made up my mind that it ought to be possible to rid him entirely of his bronchitis. I told him so and explained to him why. I put in force a rational treatment, which I also carefully explained to him, and I succeeded in completely curing him. I argued: here is an old man leading a sedentary life and requiring, therefore, to take in comparatively little energy; the food needful to supply this energy is much less than he is now taking, for he is eating as much as he ate 30 years ago when in the full flush of vigorous manhood and in the thick of all its activities. Probably one quarter of the amount he now takes would be ample. His stomach, his liver, his kidneys, &c., are now 30 years older and so much the less efficient. His digestive organs cannot cope with the large mass of food he is taking; digestion is imperfect and consequently an excess of poisons is poured into the blood; moreover, his organs of elimination being so much older and less effective, and the circulation through them sluggish, owing to his sedentary life, these poisons are not properly eliminated. As a result the blood is surcharged with them, hence follow the anæmia, the irritability, the bronchitis—probably due to an attempt on the part of the bronchial mucous membrane to get rid of the poisons—hence, in fact, most of his troubles. The treatment I adopted was as simple as it was effective. It consisted (1) in gradually cutting down the diet almost to the starvation point, so as to give the digestive organs the minimum quantity of work (when I come to treat of diet I shall show what a small quantity of food old people need); (2) in promoting elimination, to which end I persuaded the patient to take large quantities of hot water on an empty stomach till I got the skin to act well and pushed calomel and salines as far as I dared; and (3) in putting the patient through a graduated course of respiratory exercises. This not only increased the input of oxygen and the output of carbonic acid, but stimulated the circulation through the lungs and the body generally, all of which, it need scarcely be said, are desirable ends in bronchitis. Finally (4) I got the patient to spend as much time as possible out of doors when the weather permitted. Stimulant expectorants and tonics were also given, but the cure was essentially due to the adoption of the rational treatment just described. I think I may fairly call it "rational treatment." It was not a rule-of-thumb treatment, but one reasoned out to suit the special circumstances of the case. This would be my definition of rational treatment. I may say that I have since treated many similar cases, and always with benefit, so that now it has come to be a routine treatment with me. And when a treatment is routine, not specially reasoned out to suit an individual case, it is, as I have said, practically the same as empirical treatment. I wish to emphasise this point, because some—I will call them ultra-rationalists, or pseudo-rationalists—claim, or at all events seek, to treat *each particular case* that comes before them by a special process of reasoning and on strictly rational methods, a claim which I contend is as dangerous as it is presumptuous and unwarranted.

The force of my contention that a routine treatment, even though rationally devised, is for practical purposes empirical, is, I trust, obvious. It is matter of little moment to the physician who adopts such a treatment whether it originated rationally or empirically; the important fact is that it is applied as a matter of routine—without any special process of reasoning; and be it observed that all routine treatment, even that initiated on rational principles, owes its justification to the fact that it has answered the test of experience. My meaning is made clear by reference to the treatment of myxœdema by thyroid extract, and diphtheria by antitoxin. These methods are the fruit of close reasoning and prolonged experiment, but for which they might have remained undiscovered for all time; once discovered, however, they are employed in exactly the same way as we employ mercury in syphilis, and the physician need trouble himself no more about the rationale of their action than need the microscopist trouble himself about the optical principles upon which his microscope is constructed. They have come to be routine treatments.

Now, so far as drugs are concerned, I strongly advise the physician to give them on the routine principle. Let him employ certain drugs in certain cases because they have been found by experience to be good in those cases, and let him not base his treatment by drugs, as the rational pharmacologist claims to do, on an assumed knowledge of their physiological actions and of the morbid processes going on in the body. Did we possess a minute and accurate knowledge of the pathology of the diseases we are called upon to

[1] No. III. was published in THE LANCET of Jan. 19th, 1901, p. 201.

treat, and a correspondingly minute and accurate knowledge of the action of drugs, we might conceivably devise a rational system of drug treatment for each case—one that should antagonise the various morbid processes going on in the body. But think for a moment what a perfection of knowledge this implies, and of the many opportunities for error that present themselves. I say we might *conceivably* devise such a system, but common-sense tells us that it is altogether impracticable, and I repeat what I have stated elsewhere, that the physician should not allow himself to be deceived by such pseudo-scientific nonsense. I have as much respect for the alchemist of old as for the so-called "rational" pharmacologists of to-day; nay, I have more, for the old alchemists were at least sincere searchers after right methods and they did not sin against light. Suppose, for instance, we are treating a gouty patient. Such a one does not eliminate his uric acid in proper quantities, and the learned pharmacologist tells us—or used to tell us, for the view is now disputed—that salicylic acid forms with uric acid salicyluric acid, which being highly soluble is eliminated readily by the kidneys and thus increases the output of uric acid. Now shall we give salicylate of soda in gout because of this supposed action? or shall we employ a drug—this or some other—which experience has shown to be useful in gout, though we may be entirely ignorant of how it does good? Shall we, in short, employ the strictly empirical method or the pseudo-rational method? There should be no question as to our answer. If we are wise we shall follow the empirical method.

The truth of my contention is well shown by observing the principles which govern the ophthalmic surgeon in his drug treatment. It is essentially routine. Let anyone visit the out-patient department of a hospital like the Moorfields Hospital, and he will find that the surgeons there trouble themselves very little about rationale in their employment of drugs. For each affection of the eye there is laid down a routine drug treatment which has been tested over and over again, and the best way to learn how to employ drugs most effectively in these diseases is first to learn to identify the diseases, and then to fix in our minds the routine treatment for each of them. A further and even more convincing proof of the correctness of my contention is afforded by the drug treatment of diseases of the skin. Probably in no class of disease are drugs employed so effectively as in these, and it is certain that the methods adopted are essentially routine. Were a physician having no knowledge of the routine treatment of these affections to attempt to cure them on *a priori* considerations he would make a sorry mess of it. To be successful he must first learn to recognise them, and next to apply the routine treatment of the experienced specialist.

I am not, of course, contending that we should banish all rationalism from our drug treatment: what I am contending is that we should rely mainly on experience. We are guided by rational considerations when, in a case of bronchitis, for instance, we give a sudorific to make a dry skin act, an aperient to relieve constipation, or an expectorant to liquefy a viscid sputum. We can, in fact, rarely wholly eliminate the factor of rationalism. I merely wish to insist that it should be kept within proper bounds.

As with drug treatment, so with treatment in general: we should, as far as possible, rely upon sound routine—routine which has been tried and approved—while at the same time we make proper use of rationalism. The kind of "rational" treatment that I deprecate is that in which the physician is for ever meddling with his patient, watching the symptoms from hour to hour, and adopting special measures to combat the morbid processes which he believes to underlie them. I have already condemned this pernicious method in another place and in the section on the vis medicatrix. A broad, common-sense rationalism—not a meddling, finicking, pseudo-rationalism—is what is needed. Thus, if there is a source of peripheral irritation—astigmatism, impacted cerumen in the auditory meatus, a carious tooth—we seek to remove it; if a patient is over-burdened with fat we reduce his weight; if he is emaciated we try to make him fatter; if he eats too quickly we urge him to masticate properly; if the kidneys cannot get rid of the nitrogen properly we limit the nitrogenous input; and so forth. All this is simple common-sense, but it is eminently rational.

I will complete my remarks on this head by contrasting a would-be scientific, or pseudo-, rationalism with simple common-sense rationalism as applied to the treatment of a case that came before me. A man, 35 years old, was a great sufferer from indigestion, and had become pale, emaciated, nervous, and irritable. He went to the continent and consulted several specialists there. They drew off the contents of the stomach at various intervals after taking food, and examined them chemically with a view to discovering the power of the stomach to digest different articles of diet, those which were not properly digested being removed from the dietary until finally the patient was restricted to three or four. The amount of fixed and free acids was also carefully estimated and special drugs were administered in order to correct certain defects that the calculation revealed. The result of this very scientific treatment was that he steadily lost weight and that he got more anæmic, more irritable, and more nervous. Yet this treatment all sounds very plausible, and the physician who adopts it, or the like of it, in such a case as this, would no doubt persuad himself, and perhaps others, that he is very scientific and a most advanced and up-to-date exponent of scientific medicine; but he is really guilty of the worst form of pseudo-rationalism. When I saw this patient he was a veritable skeleton. I did not examine his stomach. I found that he was a great reader, that he had astigmatism, and that his teeth were not good. As he was in a very exhausted state I had him put to bed and fed up. There was no need to be very particular about his diet, for from the very beginning he digested his food quite well when the sources of irritation in the eyes and teeth were removed. If the stomach had not digested the food then I should have fed the patient per rectum and given the stomach a rest. I should, in fact, have kept to a common-sense rationalism all through.

THE ROYAL COMMISSION ON SOUTH AFRICAN HOSPITALS.

THE Commissioners appointed to consider and report upon the care and treatment of the sick and wounded during the present South African campaign, in submitting their report state that they have divided it into four parts together with the minutes of evidence and an appendix.

In Part I. is given a brief account of the proceedings taken to enable them to discharge their duties. Some observations are added upon the evidence and upon the work done by the Commission.

In Part II., without dealing with the particulars of the various complaints made as to the care of the sick and wounded in the present campaign in South Africa, they state certain conclusions come to by them on various points of a general character. They also refer to some facts important to be borne in mind when dealing in detail with those complaints.

In Part III. they investigate the complaints so far as they were of a character to require special notice and state the conclusions come to in regard to them.

In Part IV. they recommend some steps being taken with a view of remedying in the future defects observed by them in the campaign.

We shall deal with the whole report in detail. For the present we content ourselves with reprinting the suggestions of the Commissioners with a view of remedying certain defects in the Royal Army Medical Corps, as reference to these suggestions is made in a leading article this week.

SUGGESTIONS WITH A VIEW OF REMEDYING DEFECTS IN THE ROYAL ARMY MEDICAL CORPS.

In previous parts of this report, and especially in Part II., we have mentioned several matters connected with the Royal Army Medical Corps as at present constituted, and the care of our sick and wounded, in which improvements are required. The extent to which, and the way in which, these improvements can practically be made, require detailed and careful consideration by military and medical experts. We recommend the appointment at some early convenient time of a departmental or other committee of experts to inquire into and report upon the steps needed to effect the following objects:—

1. The establishment of the staff of officers and orderlies of the Royal Army Medical Corps, and its equipment, on a scale sufficient to enable it to discharge adequately the duties ordinarily cast upon it in times of peace and by the smaller wars in which the Empire by its vast extent is so frequently engaged.

2. Regulations and provisions which will enable surgeons and trained orderlies in sufficient numbers to be rapidly obtained and added to the ordinary staff of the Royal Army Medical Corps in the event of a great war; and that will also ensure a rapid supply of all hospital and other equipment required for the due care of the sick and wounded in such a war.

3. The attraction to the Royal Army Medical Corps of a sufficient and regular supply of officers of good professional attainments. And the improvement of the position of the officers by the allowance of sufficient holidays; and by provisions enabling them to become adequately acquainted with the advancements in medical and surgical science; and the necessity of employing in the higher posts men selected for their merits rather than by seniority.

4. The employment, to a greater extent than that recognised and practised until the later stages of this war, of nurses in fixed hospitals for the care of the wounded and of fever and dysenteric patients, and such others as can properly be nursed by females.

5. The appointment of properly qualified officers of the Royal Army Medical Corps to undertake sanitary duties.

And with regard to other matters:—

6. The improvement of the existing ambulance wagons.

7. The selection and employment of the form of hospital tents best suited for the reception of sick and wounded in a campaign.

We also think that the committee might usefully consider the following questions, on which we ourselves express no opinion beyond what appears in Part II. of this report:—

(*a*) Whether it is advisable and practicable to some, and if any what extent, that the Royal Army Medical Corps should have exclusive possession of and control over all necessaries for the sick and wounded (other than ordinary food and clothing, not being hospital clothing), so as to avoid the necessity of requisitioning upon the Army Service Corps or the Ordnance authorities.

(*b*) Whether the administrative and clerical duties of the principal medical officers can be lightened and in particular to what extent the reports and returns which have to be made can and should be shortened.

(*c*) Whether the men of the bearer companies, when not engaged on the field, could be employed to assist in the field hospitals, and whether with this object it is advisable that the staff of the bearer company and of the field hospital of a brigade should be under one chief officer.

(*d*) Whether in times of peace a regimental doctor should be attached to each regiment for some fixed time.

(*e*) Whether general hospitals could be advantageously divided into smaller units.

(*f*) Whether it is practicable and advisable that the reception and distribution of all charitable gifts for the sick and wounded should be by some organised body on their behalf; and if so, what that body should be.

The following are not matters for inquiry by the suggested committee. It will be sufficient if the attention of the Royal Army Medical Corps be specially called to what we are about to state, with a view to our recommendations being acted on.

Having regard to what we have said on the subject in Part II., we think that strict inquiry should be made in the various military hospitals in South Africa and proper steps be taken in order to stamp out, where it exists, pilfering by orderlies of the stimulants, comforts, or property of patients, and the receipt of bribes by orderlies from patients.

We also suggest that the officers should, so far as it is possible and consistent with due discipline to do so, relax the strict military rule generally adopted in military hospitals, so as to give an additional feeling of ease to the patients and enable them to better appreciate the comforts of a hospital.

The power and duty of every officer in this campaign in cases of emergency to buy for his hospital at the expense of the Government any necessary not in hospital and not procurable without delay elsewhere has been fully recognised by the authorities, and the power has been by many freely exercised. But, as we have already pointed out, some officers appear not to be fully acquainted with the existence of the power, and it is advisable that it should be made widely known that any exercise of that power will be favourably viewed by the authorities, unless, of course, in cases of its abuse.

THE PLAGUE AT HULL.

WE noted in THE LANCET of Jan. 26th, 1901, p. 275, that several cases of plague had occurred on board of a ship sailing from Alexandria to Hull and which is now lying in the latter port. The following is a detailed account of the outbreak and the measures taken up to the night of Jan. 30th:—

The s.s. *Friary*, with a crew of 21 hands all told, arrived at Hull on Jan. 10th with clean bills of health from Alexandria, having on board the dead body of an able seaman, aged 30 years. The crew were subjected to the usual medical inspection, and after inquiries it was believed that the death of the seaman on board was due to natural causes, and the body was duly interred on the 14th. The remainder of the crew were found to be in good health on the vessel's arrival at Hull. The vessel belonged to Cardiff and left that port on Nov. 23rd, 1900, for Alexandria, where she arrived on Dec. 10th. The crew had enjoyed good health during the outward passage. The *Friary* left Alexandria on the 22nd, took in coals at Algiers on the 30th, and left that port on the 31st direct for Hull. Only the master went ashore at Algiers.

On Jan. 13th, 1901, it was reported that two of the crew of the *Friary* were ill, and the medical officer of health again visited the ship and examined an able seaman, aged 28 years (a Greek), who sickened on the 12th, and also an able seaman, aged 30 years, who sickened on the same day. They were believed to be suffering from influenza and medical treatment was recommended. Medical advice was sought on the following day, when the medical attendant expressed himself as being of opinion that both men were suffering from influenza with lung complications. They became rapidly worse and expired on the 15th and the 16th respectively. Their bodies were subsequently removed to the city mortuary where the medical officer of health, in conjunction with Mr. Frederick Wilson, who had been called in on behalf of the owners, performed a post-mortem examination. Portions of the lungs, spleen, and inguinal glands were forwarded to the Local Government Board, and also by special messenger to Professor E F. Trevelyan, of the Yorkshire College, Leeds, for bacteriological examination. The results showed the cases to be pneumonic plague.

During the night of Jan. 14th two others of the crew, aged 25 years and 24 years respectively, firemen, became unwell, and they, along with four more of the crew, were removed to the Evan Fraser Hospital, the former for observation and the latter for isolation. Work on the vessel was suspended, and on the 17th the medical officer of health formally declared the vessel to be infected with plague. The vessel was subsequently removed from the dock to the appointed mooring station in the river, where she underwent a thorough fumigation. Those of the crew who were not removed to hospital were kept on the vessel in the river. A fireman, aged 30 years, after admittance into the hospital, sickened with similar symptoms to the others. He died on the 22nd, and from the bacteriological examination his death also was proved to be due to plague. A man who had acted as watchman on the vessel on the Monday after her arrival in port and had assisted some of the sick men reported himself at the Sanitary Office on the 21st to be sick. He was immediately removed to the hospital, where he died on the 27th. The medical attendant, who had been called in to attend some of the sick crew and who had assisted at the post-mortem examination on the two bodies already referred to, became unwell on the 18th, and on the 21st he was admitted into the Evan Fraser Hospital. Specimens of sputa were submitted for bacteriological examination and he, too, was found to be suffering from pneumonic plague. For some days he remained in a very critical condition, but there is now a marked improvement in his health. Up to the night of the 29th there had been in all seven deaths, four in hospital and three on the ship, and there is little doubt that they were all due to pneumonic plague. Another of the crew at present in hospital remains in a critical condition. On examination of the persons affected there were no enlarged glands discovered. The whole of the bodies, excepting the one on board on the vessel's arrival, were cremated at the city crematorium. The whole of the crew, the nursing staff at the hospital, and others who had been exposed to infection, have undergone Haffkine's prophylactic treatment as supplied by the Local Government Board. The names and addresses of all who had been on board or otherwise associated with the infected ship were obtained and these persons have been kept under daily observation. Subject to the remainder of the cargo being discharged into lighters before re-entering the dock, and the holds of the vessel being battened down and thoroughly stoved to the satisfaction of the medical officer of health, the vessel will be declared free from plague.

The Sanitary Committee have met daily and the Port Sanitary Authority have had several meetings, at which the medical officer of health has presented reports as to the progress of the disease, and the authorities are taking every precaution to prevent any spread of the disease. As previously stated there had been no sickness noticed amongst the crew except that of the one who was dead on the vessel's arrival, and the origin of the outbreak remains obscure. It should be stated, however, that some of the crew had discovered dead rats on board after the vessel left Alexandria, and a cat which went on board at the latter port had shown signs of illness. Unfortunately, the cat was thrown overboard when the vessel left for the mooring-station. The dog on board the ship, which was ailing, was killed. Portions of the viscera have been submitted for examination, but the bacteriological test has not yet been completed.

The *Friary* was released from quarantine on Jan. 30th and is discharging cargo. The master, his wife, and nine others who have been under observation were also discharged from hospital on Jan. 30th. No further cases have arisen and it is a matter for satisfaction that the outbreak has been kept in hand and confined to the one centre of contagion.

HISTORY OF THE HOUSING QUESTION IN LONDON.

PART III. AND CONCLUSION.[1]

THE FINANCIAL DIFFICULTY.

FIRST among the many financial difficulties is the fact, already mentioned, that land which might have been sold at 1*s*. 2*d*. the square foot for ordinary commercial purposes was sold by the Metropolitan Board of Works for only 3*d*. the square foot when the restriction that it was to be used for building workmen's dwellings was imposed. To-day such land would be worth a great deal more. This means a large debt and a heavy burden for the amortisation of such a debt. The London County Council proposed that the value of the land should not be included in the sum that had to be repaid, but be treated as a permanent asset. As, however, the Treasury had already refused to extend the time of amortisation from 60 to 100 years, it considered that this proposal was simply an indirect means of extending the time of amortisation, and therefore would not give its assent. Yet it was argued that the dwellings to be built would be so well built that they would certainly last 200 if not 300 years, and therefore there was no necessity to pay back all the money expended within 60 years. On the other hand, who can say what far-reaching changes may take place in the course of 100 years? A radius of about an hour's railway ride from Manchester now embraces a population of some 10,000,000 persons. Who could have foreseen a century ago such a development? London has also grown with alarming rapidity, but a reaction may set in. Then another difficulty arose. The cost of building materials and of building greatly increased. Bricks which could be had at from 30*s*. to 35*s*. per 1000 in 1890 cost 42*s*. per 1000 in 1897 and 1898. The value of cement has increased 20 per cent. and iron and steel work about 27 per cent. The labourers' wages, which were 6*d*. per hour in 1890, rose gradually to 7½*d*. per hour in 1897 and the wages of bricklayers from 9*d*. to 11*d*. per hour. Also the number of bricks laid per day is less, so that altogether brickwork which cost £11 per rod in 1890 cost £20 15*s*. per rod by the end of 1898.

An increase of wages undoubtedly augments the cost of building, but there is a counterbalancing advantage, for it adds to the rent-paying capacity of the persons engaged in building trades; and when the building trades prosper it generally means that many other trades are also prospering. Nevertheless, and though the community may thus be better able to pay both rents and taxes, the latter are so unevenly distributed that it is most difficult to get money precisely where it is most wanted. Thus it is in those districts where there is the greatest need for better dwellings that the rates are already so high as to render it almost impossible to add to this burden. In Poplar, for instance, the rates amount to 8*s*. 1*d*. per £. Nor would an increase in the rents charged suffice to meet the case, for this would be followed at once by an increase in the assessment, unless, of course, the lodgings were municipal property. In this latter case it would not matter, for whether the local authority gets the money in the form of taxes or of rent it amounts to the same thing. It might alter the aspects of the accounts; it would not alter the condition of the public purse. As to which of the two, private companies or the county council, would be the best manager the statistics published leave the matter open to doubt, and in any case the difference is not very great. The expenditure, including unlet tenements, loss of rent, caretakers' quarters and repairs, &c., was equal to 51·39 per cent. of the rents received by the county council in 1896–97 and to 47·70 per cent. in 1897–98. For the private companies it has varied in different years from 37·22 to 52 05 per cent Their average is a little lower, but the private companies have spent less in repairs and this may cost them more in the long run and is not so favourable to the well-being of the tenants. It would be false economy to reduce the expenditure in regard to repairs, but an economy has been recently effected by the county council in regard to collecting rents by amalgamating the duties of management and rent collection. This, it is thought, will economise 2·52 per cent. of the gross rental. As the rent-roll of the London County Council in 1899, when this matter was discussed, amounted to about £30,901 per annum this meant a saving of £780.

In dealing with the question of ways and means we have to consider the opinion of the valuer to the London County Council. Setting agricultural land aside, he maintains that local taxation places the heaviest burden on the least valuable building land. An example is given. A market gardener pays £5 rent for an acre of land. To make roads and to lay this land out for building purposes will cost £400 and, if it is divided up into 20 building plots it will pay to let this land at £2 ground-rent per plot. This is, however, not the practice of ground landlords. They prefer to keep the ground vacant till such time as they can obtain £5 or more per plot. Thus the ground landlord, instead of receiving £40 per year for the £400 he has spent receives £100 a year, or 25 per cent. But it is the builder and the tenant who have to pay this large interest. The houses will probably cost the builder £300 each, and as he is not likely to be content with less than 6 per cent. interest he must charge £18 to produce such interest. Then he must charge £6 more for repairs and insurance and some £7 for local taxes; this makes £31, so that with the £5 for the ground-rent the tenants must pay in all £36 for each of the 20 houses built on the one acre of ground that as a market garden only produced £5 a year or £6 with taxes. The acre will have to yield £140 in taxes and £100 in ground-rent, total £240, instead of £6, or a fortyfold increase. Though the value of land in and about London is rising rapidly, yet, and in spite of tramways and "twopenny tubes," many years must elapse before an augmentation of 40 times its present value can be realised. In the meanwhile, the value of the land in the central parts of the metropolis is forced up because the land in the outskirts is withheld from the market. The valuer urges as a remedy for this state of affairs that if rates and taxes were calculated according to the site value only, and were levied on all vacant as well as all covered land, the present system of "cornering" land would break down. Land could then be obtained when it yielded 4 or 5 per cent. to the owner instead of being withheld till it yielded from 20 to 30 per cent. Both in Paris and in Berlin the same demand in favour of taxing land withheld from the market has been made.

Having now summarised the account given of the difficulties that beset the housing problem and the efforts of the Legislature to deal with these obstacles we are naturally anxious to inquire what, after all and in spite of all, has been done. For how many people have new and better homes been constructed, and of all the laws enacted which have been the most generally applied and found to be the most useful? This is not clearly explained in the work on the housing question issued by the London County Council. Each great scheme is separately described with accompanying plans, and there are also tables and summaries of these tables, but still it is difficult to understand. For instance, at the very beginning of the story we are told that the London County Council when they came into office at once set to work "erecting" buildings for 2000 persons in respect to the obligation left by the Metropolitan Board of Works. But as these schemes of the defunct board were framed under Part I. of the Act what business had the Council to erect buildings? Then we are told that from 1889 to 1900 the Council have displaced 7845 persons and have accommodated 6956 persons, while dwellings are in the course of erection for 4956 persons and 8339 will be displaced, but it is not clear how these people are going to be, or have been, re-housed. Will they be re-housed by private companies under Part. I. of the Act or by the county council under Part III. of the Act? These figures indicate that 16,184 persons have been, or will be, displaced and that only 11 912 have been or will be re-housed. This shows a deficit therefore of 4272 persons, who seem destined to increase the overcrowding already existing. But there follows immediately after other figures that present quite a different picture The London County Council, availing themselves of the Housing of the Working Classes Act of 1890, have displaced 7845 persons, the same figure as given above, but they have housed 9198, including those who were left over by the Metropolitan Board of Works. As this cost in clearance £524,750 it was apparently done under Part I. of the Act. The recoupment was £118,850, and the net loss was £405,900.

[1] Parts I. and II. were published in THE LANCET of Jan. 12th (p. 124) and Jan. 19th, 1901 (p. 205.)

Still another table sets forth that 3996 persons are being displaced and 4343 will be displaced, which if added to the 7845 mentioned above make a total displacement of 16,184, but then 5646 more persons are to be housed, and this with the 9198 mentioned in the previous set of figures makes another total of 14,844 either housed or to be housed. Here, then, we have the deficit reduced to 1340. But in the tables given it is stated that the number to be re-housed will be 16,894, though the total, according to the details, is only 14,844. Perhaps this discrepancy may be explained by the fact that the smaller figure comprises only those for whom houses were actually in course of construction at that time. On inquiry we have ascertained that this figure of 16,184 persons is the sum total of re-housing prepared by the county council up to the date of March 30th, 1900. The gross cost of these clearances is £1,028,800, the recoupment is £289,900, and the net loss is £738,900. These summaries do not give the cost of the dwellings erected because they are all designed to be self-supporting. But if these dwellings do not belong to the county council it is not the business of that council to reckon whether they will be self-supporting or not. As it was not till the year 1898 that a resolution was adopted by the council recommending that Part III. of the Act should be applied, and as these schemes are associated with clearances that can only be effected under Parts I. and II. of the Act, it would seem that Part III. does not apply to these operations, that the council could scarcely be expected to erect these dwellings and itself rent them out to tenants; but, having effected the clearance, the land should have been sold to companies who would undertake to build artisans' dwellings at their own risk and peril. This, according to the text of the law, is what should have been done. As a matter of fact nothing of the sort was done and it is a pity that the measures that were taken have not been more clearly explained.

The London County Council were on the horns of a dilemma. The law rendered the clearing of insanitary areas not optional but obligatory; on the other hand, when the costly clearances had been effected it was found to be no longer possible to sell the land with the conditions imposed of building workmen's dwellings upon it. The artisan dwellings companies, the Peabody Trust, and such bodies had already bought from the Metropolitan Board of Works as much land as they could manage, and by the time the London County Council came into power their spirit of enterprise had exhausted itself. Yet and though there was no purchaser forthcoming the land could not be allowed to remain vacant. Fresh insanitary areas were being denounced and condemned, more clearances had to be made, and, of course, the demand for new houses to replace those pulled down increased in intensity. But no one would undertake to build these new houses, and it seemed as if matters would drift from bad to worse. It then occurred to the London County Council that they might solve the difficulty by themselves becoming a building company. They would purchase the land from themselves for themselves. Hence we see the otherwise astounding and inexplicable heading "recoupment." So much is set down as the cost of a clearance and then there follows an estimated recoupment, yet we know that no one has bought the land of the clearance from the county council and therefore there can have been no recoupment. The county council simply reckoned that if they had sold the land with the obligation imposed on the purchaser to build upon it only workmen's dwellings the purchase price paid would have amounted to the sum put down as recoupment. This then represents what would be the market value of the land if sold with the obligations imposed by the law. Most of the land cleared of its slums could have been sold for three or four times this sum if these obligations were not imposed. The county council placed themselves in the position of an artisans' dwellings company and considered themselves indebted to their own treasury for the amount which in all probability the treasury would have received had it been possible to sell the land to a private company. Then the county council set about building on that land just as a private company would have done; that is to say, to build houses that would bring in enough to pay the cost of purchasing land, of building, of working expenses, of interest on borrowed money, and to provide a sinking fund. The only difference was that the county council did not seek to realise a net profit over and above these charges.

Thus we have had municipal enterprise stepping in to do what private enterprise shrank from attempting. This is surely a most important—indeed the most important—feature of the entire question. If it is not carefully explained all the details about building plans, the size of the rooms, the methods of collecting rent, the cost of management and repairs, so lengthily discussed by the London County Council and described in their published history of the question, seem to be altogether out of place. Such details would apply to the carrying out of a scheme under Part III. but not to a scheme under Part I. of the Act.

At first sight it looks as if the London County Council had applied Part I. of the Act to effect the clearances and then Part III. to purchase the land that had been cleared, and this would probably be a good solution of the problem. Unfortunately this is not legal. It is true that under Part III. the county council are empowered to buy land, to build upon it, and to retain the ownership of both land and buildings. The borough councils now also possess this power. But this does not come under the heading of clearances; a scheme is not necessary; the houses purchased need not be in an insanitary condition; indeed, land can be purchased on which there are no houses at all. On the other hand, the county council or the borough councils must effect such purchases in the ordinary manner. The purchase may be compulsory if approved by the Secretary of State and confirmed by Act of Parliament, but the stipulations in Part I. and Part II. which tend to limit and reduce the amount of compensation given in effecting a clearance of insanitary areas do not apply to purchases under Part III. of the Act. This was inaccurately explained in our issue of Jan. 19th through the accidental omission of the word "not." The position, therefore, stands thus: Districts condemned as insanitary areas must be cleared by the county council or by the borough councils. But while the local authority is thus compelled to buy up the insanitary area it is not allowed to keep the land for more than 10 years unless special permission is given to that effect. If there were ready purchasers for the land this obligation might not be so very burdensome; but, as matters now stand, we are face to face with this absurd position, that the local authorities must purchase land with the obligations to sell it though it is well known that there are no purchasers forthcoming. Fortunately the Act provides that the Secretary of State may give permission to the local authority to retain the land. If this permission were granted at the onset then the local authority might safely venture to build. But this is not the way the Act is applied. The permission to retain the land will only be accorded, if it is given, at the expiration of the 10 years. Under these circumstances the only business-like and safe procedure is for the local authorities not to build till they have acquired the certitude of being able to retain possession of the land. This, however, would be most disastrous. It would apparently retard the re-housing of the poor for 10 years and cause most valuable sites to remain unutilised for that lengthy period. The London County Council have had the courage, however, to face the risk and to build on the clearances though they may be compelled to sell the land at the expiration of the 10 years. It is not anticipated that this clause of the Act will be enforced, but there is nothing in the law to protect the county council; it all depends on the Secretary of State, who might refuse to give the county council special permission to retain the land. In that case the elaborate calculations made would fall to the ground and the buildings erected for the re-housing of the poor together with the land on which they stand would have to be sold probably at a disastrous loss. The mere mention of such a possibility, however unlikely, shows that the law is still in an unsatisfactory condition. Evidently the local authorities ought to be specifically allowed to retain land cleared under Parts I. and II. of the Act; at least if they are willing to pay as much as any private company offers. Even then the local authorities would be at a disadvantage as compared with private companies; for the former are compelled to refund their capital expenditure within 60 years, whereas no such obligation exists with regard to any private company or enterprise.

Taught by this experience, the London County Council are inclined to avail themselves more and more of Part III. of the Act. Unless the purchase is to be compulsory the local authorities can proceed, under Part III., with all the freedom of private enterprise. They have simply to watch for good bargains and buy the land needed wherever it can be found, whether this be within or without the boundaries of the metropolis. The land thus purchased and the dwellings built or already existing

upon it become public property in perpetuity, the only obligation being the creation of a sinking fund so that the capital expenditure may be repaid within 60 years. In some districts this is financially possible but with regard to the old slums many of them are too near the commercial centres and the land is too valuable for the erection upon them of artisans' dwellings on a profitable basis. Thus we have the terrible difference of the cost of the clearances given in one of the estimates quoted above at £1,028,800, while the value of the land thus acquired is put down at only £289,900; because it must be employed exclusively for the purpose of re-housing the working classes. Under Parts I. and II. of the Act this heavy loss is thrown upon the rates and thus the community at large is made to pay for the sins of those who brought the slums into existence. This is not a pleasing situation. It would be more gratifying if the culprits were tracked out and forced to pay; but this seems to be a case of the sins of the fathers being visited upon the sons.

The worst is that all these sacrifices have not solved the problem. It is estimated that the population of the County of London has increased by more than 700,000 persons since 1881. If these newcomers have also their submerged tenth, this means some 70,000 more people who are not in a position to pay high enough rents to secure healthy homes. The population it is true has decreased in such central districts as Marylebone, the Strand, Westminster, and St. James's in the proportion of from 10 to 27 per cent. Then there has been a smaller reduction of population in Clerkenwell, Shoreditch, Limehouse, and Bermondsey. But this does not mean less overcrowding. It only implies that a large number of dwelling-houses have been converted into business premises, and the ever-increasing demand for business premises renders it very difficult to re-house the poor on the same spot when they live in central districts. The Midland Railway Company at Somers Town has pulled down some 500 houses and displaced about 6000 persons. In the face of all this, what has been done to re-house the poor seems very inadequate, though it represents an immense amount of work achieved in the face of endless difficulties. Taking the most favourable and recent view of the situation Mr. David S. Waterlow, L.C.C., explains in the *Fortnightly Review* of January that the areas cleared by the London County Council and left vacant by the Metropolitan Board of Works displaced 16,602 persons, and that 13,847 have now been re-housed. The county council are now not only providing for the balance, but for a much larger number. Part III. of the Act will in future be so extensively applied that there are plans now being studied for housing 23,838 persons under this section; but as such plans are pure building speculations and must be made to pay commercially they require much forethought and caution. The schemes now completed or where the buildings are in course of erection comprise 74 block buildings, cottages, and one lodging-house. These will provide for 16,352 persons. Plans of buildings are being prepared and the necessary land is already acquired to house 14,853 persons. Finally, the purchase of land has been sanctioned on which 5800 more persons will be able to find homes. This gives a grand total of 37,005 persons who will be housed by the county council when the schemes now in hand are completed. Apart from this the London County Council are also negotiating for the purchase of 250 more acres of land. Indeed, under Part III., more and more land is being bought. Two plots were thus purchased last December and another plot last week. The history of the housing question at the close of the volume and in the last of the many estimates given sets down the net cost of the clearances effected by the Metropolitan Board of Works in the most recently corrected estimate at £1,605,088; those effected by the London County Council up to the month of March last cost £1,045 050, and adding to these figures the smaller sums spent by district authorities we have a grand total for clearing insanitary areas of £2,898,616. The estimated cost of dwellings—including the value of the land as appraised with the obligations imposed and all incidentals—constructed by the London County Council is £1,221 418, and the gross rent receivable per annum from this property and in respect to tenements actually occupied was in March last £35,164. The district authorities also received £1527 in rent for tenements of dwellings that had cost them £27,336. The total number of persons provided for or to be provided for under all these headings or schemes amounted to 64,428, including those housed by companies who bought land from the Metropolitan Board of Works, and 2452 persons housed by district authorities. Those who live or are to live in tenements constructed by the county council will number about 34,000, though Mr. David S. Waterlow sets down this figure at 37,000, but his estimate is of a later date.

In conclusion, it will be seen that of late much greater activity has been shown in respect to the housing question. The London County Council are displaying more boldness and a more hardy spirit of enterprise. They see their way to making some of the schemes pay and this is a great encouragement, and considering the gravity of the situation such encouragement is much needed.

THE BATTLE OF THE CLUBS.

THE COVENTRY DISPENSARY AND THE BIRMINGHAM AND MIDLAND COUNTIES BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

THE Coventry Dispensary, to which we have referred upon many previous occasions, has received a very rude shock from the hands of the Birmingham and Midland Counties Branch of the British Medical Association.

On Jan. 10th last Dr. E. Phillips of Coventry referred to the medical officers of this institution before the above-named branch and proposed the following resolution:—

That inasmuch as the Coventry Provident Dispensary has been condemned by the Ethical Committee of the Birmingham and Midland Counties Branch of the British Medical Association, by the Council of the Association, and by the members assembled at annual meetings, it is proposed that in the opinion of this meeting no professional recognition should be given to medical men holding appointments in this institution by any member of the Birmingham and Midland Counties Branch of the British Medical Association.

Dr. Phillips pointed out that the institution had been condemned by the British Medical Association at three annual meetings, by the Council of the Association, by the Ethical Committee, as well as by the journal of the Association; that THE LANCET had sent a Special Commissioner to Coventry who had condemed it in the strongest terms; and that the medical press had refused the advertisements for vacancies. That in 1896 the dispensary medical officers had presented a memorial to their committee in which they admitted the abuses complained of and asked for their reform, but the reply which they received was that if they were not satisfied with their positions another staff could be procured to take their places. Since then a few minor alterations had been made, but the dispensary still had no wage limit and the medical officers were entirely in the hands of a lay committee who did not hand over all the money received and thus exploited them. In addition clubs and members were taken at a lower rate of payment than other medical men in the town accepted, and well-to-do people took advantage of the benefits of the institution.

At a later meeting held on Jan. 24th, when the same resolution was under discussion, the dispensary medical officers replied to these statements and admitted that well-to-do people were members of the institution. They did not, however, avail themselves of the benefits, having joined when they were not so well off, and they still retained their membership in order to support the dispensary. The resolution was carried with six dissentients. As the number present was 160 or more the feeling expressed was practically unanimous.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6708 births and 4039 deaths were registered during the week ending Jan. 26th. The annual rate of mortality in these towns, which had been 19·1 and 19·6 per 1000 in the two preceding weeks, further declined to 17·9 last week. In London the death-rate was 17·6 per 1000, while it averaged 18·1 in the 32 large provincial towns. The lowest death-rates in these towns were 10·5 in Portsmouth, 11·6 in West Ham, 12·7 in Blackburn, and 13·0 in Burnley; the highest rates were 21·9 in Birkenhead, 23·7 in Norwich, 24·0 in Liverpool, and 24·6 in Gateshead. The 4039 deaths in these towns included 347 which were referred to the principal zymotic diseases, against 389 and 374 in the two preceding weeks; of these 92 resulted from whooping-cough, 75 from diphtheria, 58 from measles, 48 from "fever" including

five fatal cases of "pneumonic plague" in Hull), 43 from diarrhœal diseases, and 31 from scarlet fever. No death from any of these diseases occurred last week in Huddersfield; in the other towns they caused the lowest death-rates in Portsmouth, Burnley, and Newcastle, and the highest rates in Norwich, Nottingham, Salford, and Sheffield. The greatest mortality from measles occurred in Wolverhampton and in Liverpool; from whooping-cough in Bristol, Nottingham Oldham, and Sunderland; from "fever" in Derby and in Hull; and from diarrhœal diseases in Oldham. The mortality from scarlet fever showed no marked excess in any of the large towns. The 75 deaths from diphtheria included 23 in London, 10 in Sheffield, five in Bristol, five in Leicester, and four in Leeds. No fatal case of small-pox was registered in any of the 33 towns; three new cases were admitted into the Metropolitan Asylums Hospitals during the week and remained under treatment on Saturday last, Jan. 26th. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2078, against numbers declining from 2535 to 2171 on the four preceding Saturdays; 172 new cases were admitted during the week, against 163, 156, and 187 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had risen from 306 to 422 in the five preceding weeks, declined again to 394 last week, and were 142 below the corrected average. Influenza was certified as the primary cause of 16 deaths in London last week, against 10 and 20 in the two preceding weeks. The causes of 40, or 1·0 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Leicester, Salford, Leeds, and 10 other smaller towns; the largest proportions of uncertified deaths were registered in Nottingham, Liverpool, Manchester, and Blackburn.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·2, 21·9, and 24·0 per 1000 in the three preceding weeks, declined again to 21·1 during the week ending Jan. 26th, but was 3·2 per 1000 above the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 6·7 in Perth and 14·5 in Aberdeen to 21·5 in Paisley and 24·4 in Glasgow. The 663 deaths in these towns included 39 which were referred to whooping-cough, 18 to measles, 15 to "fever," 15 to diarrhœa, 11 to small-pox, and eight to diphtheria. In all, 106 deaths resulted from these principal zymotic diseases, against 76, 101, and 125 in the three preceding weeks. These 106 deaths were equal to an annual rate of 3·4 per 1000, which was 1·9 per 1000 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping-cough, which had been 29, 49, and 61 in the three preceding weeks, declined again last week to 39, of which 28 occurred in Glasgow, four in Dundee, three in Edinburgh, and two in Leith. The deaths from measles, which had been 12 and 23 in the two preceding weeks, declined again to 18 last week, and included eight in Edinburgh, seven in Aberdeen, and two in Dundee. The fatal cases of "fever" which had been two, two, and 14 in the three preceding weeks, further rose last week to 15, of which 11 were registered in Glasgow and three in Aberdeen. The deaths from diarrhœa, which had been 22 and 16 in the two preceding weeks, further declined to 15 last week, and included 12 in Glasgow. The fatal cases of small-pox, which had been three, two, and three in the three preceding weeks, further rose last week to 11, of which 10 were recorded in Glasgow and one in Greenock. The deaths from diphtheria, which had been eight and six in the two preceding weeks, rose again last week to eight, and included three in Edinburgh and two in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 105, 123, and 139 in the three preceding weeks, further rose last week to 145, but were 27 below the number in the corresponding period of last year. The causes of 19, or nearly 3 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 28·3 and 30·4 per 1000 in the two preceding weeks, declined again to 28·2 during the week ending Jan. 26th. During the past four weeks the death-rate in the city has averaged 29·1 per 1000, the rate during the same period being 18·5 in London and 21·7 in Edinburgh. The 187 deaths belonging to Dublin registered during the week under notice were 15 less than the number in the preceding week and included 20 which were referred to the principal zymotic diseases, against 23, 18, and 16 in the three preceding weeks; of these, eight resulted from whooping-cough, six from "fever," three from diarrhœa, two from diphtheria, and one from scarlet fever. These 20 deaths were equal to an annual rate of 3·0 per 1000, the zymotic death-rate during the same period being 1·4 in London and 2·5 in Edinburgh. The fatal cases of whooping-cough, which had been 10 and 12 in the two preceding weeks, declined again last week to eight. The deaths referred to "fever," which had been three in each of the three preceding weeks, increased to six last week. The 187 deaths in Dublin last week included 32 of children under one year of age and 59 of persons aged upwards of 60 years; the deaths of infants showed a decline, while those of elderly persons exceeded the number in the preceding week. Four inquest cases and four deaths from violence were registered during the week; and 77, or more than two-fifths, of the deaths occurred in public institutions. The causes of two, or 1·1 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING 1900.

Complete statistics relating to sickness and mortality during the year 1900 in each of the 43 sanitary areas of London are summarised in the accompanying table. The mortality figures relate to the deaths of persons actually belonging to the various sanitary areas, and are the result of a complete system of distribution of deaths occurring in the institutions of London among the various sanitary areas in which the patients had previously resided. With regard to the notified cases of infectious diseases in London during 1900, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 7·7 per 1000 of the population, estimated at 4,589,129 persons in the middle of the year. In the three preceding years the rates had been 10·2, 8·3, and 9·3 per 1000 respectively. Among the various sanitary areas the lowest rates were 4·3 in St. Martin-in-the-Fields, 4·5 in St. George Hanover-square, 5·0 in Paddington, 5·7 in Kensington, and 6 0 in Chelsea, in St. James Westminster, in Hampstead, and in Clerkenwell; the highest rates were 9·3 in Bermondsey, 9·5 in Poplar, 10·1 in Plumstead, 10·5 in St. Saviour Southwark, 10·7 in Fulham and in Whitechapel, and 12·1 in St. George Southwark. The prevalence of small-pox in London during 1900 was greater than it had been in the preceding year; the new cases notified being 88, against 104, 32, and 29 in the three preceding years; of these, 16 belonged to Hackney, 9 to Fulham, 7 to Kensington, 7 to St. Pancras, and 7 to St. George-in-the-East sanitary areas. The number of small-pox patients admitted into the Metropolitan Asylums Hospitals during 1900 was 82 and one remained under treatment at the end of the year. The prevalence of scarlet fever in London during 1900 showed a considerable decrease compared with that recorded in the preceding year, the number of cases notified being 13,809, against 22,850, 16,894, and 18,094 in the three preceding years; this disease was proportionally most prevalent in Fulham, Whitechapel, St. George Southwark, Greenwich, Lewisham (excluding Penge), and Plumstead sanitary areas. During the year under notice 10,734 scarlet fever patients were admitted into the Metropolitan Asylums Hospitals, against 15,256, 12,480, and 13,641 in the three preceding years; the number of cases under treatment, which had been 3506, 2883, and 2797 at the end of the three preceding years, had further declined to 2460 on Saturday, Dec. 29th last. Diphtheria showed a slightly decreased prevalence in London last year, the cases notified being 11,994, against 11,855 and 13,692 in the two preceding years; this disease showed the greatest proportional prevalence in Fulham, Stoke Newington, Poplar, St. Saviour Southwark, St. George Southwark, Bermondsey, and Lee sanitary areas. The Metropolitan Asylums Hospitals contained 1679 at the beginning of 1900; 8777 cases were admitted during the year, and 1343 remained under treatment at the end of December last. The prevalence of enteric fever in London during the year under notice showed a slight decline from that recorded in the preceding year, the number of notified cases being 4306, against 3024 and 4456 in the two preceding years; among the various sanitary areas this disease

* Including 209 cases of membranous croup. † Including deaths from membranous croup. ‡ Bubonic disease.

NOTE.—In order to show uniform statistics for the year the changes made under the London Government Act (1899) are not taken into account in the above table.

was proportionally most prevalent in St. Pancras, St. George-in-the-East, Poplar, St. George Southwark, Bermondsey, and Rotherhithe. The number of enteric fever patients admitted into the Metropolitan Asylums Hospitals during 1900 was 2074, against 939, 1116, and 1835 in the three preceding years; 403 cases remained under treatment at the end of December last, against 406 at the end of 1899. Erysipelas showed the highest proportional prevalence in Bethnal Green, Whitechapel, St. George-in-the-East, Limehouse, Mile End Old Town, and Rotherhithe sanitary areas. The 237 notified cases of puerperal fever were 93 below the number recorded during 1899; 16 cases belonged to Islington, 15 to Hackney, 15 to Wandsworth, 12 to Lambeth, 11 to St. Pancras, and 11 to Greenwich sanitary areas.

During the year under notice the deaths of 83,732 persons belonging to London were registered, equal to an annual rate of 18·3 per 1000, against 17·7, 18·3, and 19·3 in the three preceding years, 1897–8–9; the average rate in the 10 years 1890–1899 being 19·4 per 1000. In the various sanitary areas the lowest death-rates were 11·3 in Hampstead, 12·6 in Stoke Newington, 13·8 in St. George Hanover-square, 14·8 in Wandsworth, 15·1 in Lee, and 15·7 in Lewisham (excluding Penge); the highest rates were 24·4 in St. George in the East, 25·2 in St. Saviour's Southwark, 26·1 in Limehouse, 26·5 in Holborn, 26·8 in St. Luke, and 27·3 in St. George Southwark. Taking the five groups of sanitary areas the rates of mortality during 1900 were 16·6 per 1000 in the west, 16·7 in the north, 18·0 in the south, 21·9 in the east, and 22·3 in the central. To the principal zymotic diseases 10,034 deaths were referred during the year under notice; 3532 resulted from diarrhœa, 1945 from whooping cough, 1928 from measles, 1539 from diphtheria, 725 from different forms of "fever" (including two from typhus, 716 from enteric, and seven from simple continued fever), 361 from scarlet fever, and four from small-pox. These 10,034 deaths were equal to an annual rate of 2·19 per 1000, against 2·57, 2·77, and 2·46 in the three preceding years, 1897–8–9. Among the various sanitary areas the zymotic death-rates ranged from 0·78 in St. George Hanover-square, 0·84 in St. Martin-in-the-Fields, 0·89 in City of London, 1·08 in St. James Westminster, 1·14 in Strand, and 1·18 in Hampstead, to 3·24 in Bermondsey, 3·25 in St. Luke, 3·34 in Poplar, 3·40 in Rotherhithe, 3·53 in St. George Southwark, and 4·10 in Limehouse. The four fatal cases of small-pox registered in London during 1900 were 39 below the corrected average number in the 10 preceding years; two cases belonged to Marylebone, one to Islington, and one to Woolwich sanitary areas. The 1928 deaths referred to measles were 886 below the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Hammersmith, Holborn, St. Luke, Limehouse, Rotherhithe, and Plumstead. The 361 fatal cases of scarlet fever were 554 below the corrected decennial average; the greatest mortality from this disease occurred in Fulham, Clerkenwell, City of London, Limehouse, St. George Southwark, and Rotherhithe sanitary areas. The 1539 deaths referred to diphtheria were 706 below the corrected average number; among the various sanitary areas this disease was proportionately most fatal in Poplar, St. Saviour Southwark, Newington, Bermondsey, and Rotherhithe. The 1945 fatal cases of whooping-cough were 484 below the corrected average number; this disease showed the highest proportional fatality in Clerkenwell, St. Luke, Bethnal Green, Limehouse, St. Olave Southwark, and Bermondsey sanitary areas. The 725 deaths referred to different forms of "fever" were 101 above the corrected average number; among the various sanitary areas the "fever" death-rate was highest in St. Pancras, St. Martin-in-the-Fields, Poplar, St. Saviour Southwark, Bermondsey, and Rotherhithe. The 3532 fatal cases of diarrhœa were 153 above the corrected decennial average; this disease was proportionately most fatal in St. Luke, Shoreditch, Poplar, St. Saviour Southwark, St. George Southwark, and Woolwich sanitary areas. In conclusion, it may be stated that the mortality in London during 1900 from these zymotic diseases was in the aggregate more than 19 per cent. below the average.

Infant mortality in London last year, measured by the proportion of deaths under one year of age to registered births, was equal to 158 per 1000, against 166 in each of the two preceding years. The rates of infant mortality in the various sanitary areas ranged from 100 in Hampstead, 107 in St. George Hanover Square, 108 in Stoke Newington, 118 in St. Giles, 120 in St. Olave Southwark, and 125 in Marylebone, to 192 in Poplar, 197 in St. Saviour Southwark, 205 in Rotherhithe, 209 in St. George Southwark, 228 in Limehouse, and 240 in Holborn.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff-Surgeon J. E. Coad to the *Hotspur*. Surgeons: P. G. Williams to the *Alert*; P. H. Bannister to the *Rattler*; A. C. Renwick to the *Benbow*; M. L. B. Rodd to the *Phœbe*; J. Mowat to the *Vivid* for Devonport Dockyard; and H. W. Finlayson to the *Terpsichore*.

ROYAL ARMY MEDICAL CORPS.

Captain C. T. Samman proceeds to Woolwich for temporary duty in the Royal Arsenal. Colonel H. Comerford, P.M.O., South-Eastern District, having been placed on the sick list, his duties will be performed by Lieutenant-Colonel J. Lees Hall. Lieutenant-Colonel G. F. Poynder (r.p.) is appointed Medical Officer in charge of the troops at Bedford. Captain A. E. Milner has embarked for India.

THE KING'S MESSAGE.

The message of His Majesty the King to the Royal Navy was read at the Royal Naval Hospital, Haslar, by Inspector-General J. W. Fisher on Jan. 29th.

THE DEATH OF THE QUEEN.

Amongst the floral tributes sent to Osborne was a magnificent wreath from the sick and wounded soldiers at Netley Hospital composed of arum lilies, camellias, tuberoses, lilies of the valley, azaleas, tulips, hyacinths, and evergreen, and bearing the following inscription: "With deepest sympathy to our beloved Queen, from the sick and wounded at Netley." The officers of the hospital sent a floral crown.

DEATHS IN THE SERVICES.

Staff-Surgeon J. Steel, of the New South Wales Naval Forces, accidentally while on active service with the naval contingent at Taku in China, aged 45 years.

Captain Bernard Henry Frederick Leumann, I.M.S., suddenly on Jan. 7th at his residence, Wallington, in his thirty-second year. He entered the service in 1894 and was promoted to Captain in 1897.

SOUTH AFRICAN NOTES.

Lieutenant L. F. Forbes Winslow, R.A.M.C., was reported dangerously ill from enteric fever at Pretoria on Jan. 22nd.

The *Tantallon Castle* left for England on Jan. 17th, having on board Civil Surgeons E. A. Houseman, W. H. Pegg, and H. A. Ballance.

The *Salamis* left for England on Jan. 21st, having on board Civil Surgeons W. A. Stott, W. P. Park, and A. Taylor.

The *St. Andrew* left for England on Jan. 22nd, having on board Civil Surgeon R. M. W. Wilson.

THE WAR NEWS FROM SOUTH AFRICA.

Apart from the news of the proclamation of the Accession of King Edward VII. in the capital of what was once the South African Republic there is but little news of a satisfactory character to be chronicled. The war, as we are still compelled to term it, consists of fighting of a desultory character. It drags its weary course along, but has at the present moment reached a somewhat stagnant stage. Beyond a series of marauding attacks by the Boer forces in many directions, in which they occasionally succeed in doing a great deal of damage, as in the recent attack on the Kleinfontein mine at Johannesburg, there is nothing to record. We know little or nothing of the Boer plans or of the movements of De Wet and their other generals, and for the time being we hear next to nothing from Lord Kitchener or of the movements of General French and General Knox. This is the hot season in South Africa, and the weather is a possible cause of inaction, while the horses are getting needful rest. The deaths from disease are mainly attributable to enteric fever, which continues to be the chief source of sickness and inefficiency. The fighting, although on a small scale, is of frequent occurrence, and almost every encounter, however unimportant, nevertheless adds its quota of casualties to the list of killed and wounded.

LEAN'S ROYAL NAVY LIST.

This publication has now reached its ninety-third number and deals with the career of some 10,000 naval officers.

Among the contents of this well-known and useful compilation will be found the war and meritorious services of officers, the names of famous battleships, dates of commissions and retirements, royal orders, medals, decorations, &c., and the story of the services for which the Victoria Cross has been bestowed. Not the least valuable part of the book is the complete alphabetical list of the officers of the Royal Navy and Royal Marines. Messrs. Witherby and Co., 326, High Holborn, and Newman's-court, Cornhill, are the publishers.

Correspondence.

"Audi alteram partem."

"ISOLATION HOSPITALS."

To the Editors of THE LANCET.

SIRS,—Three of the 33 large towns of England and Wales may be dismissed from consideration because isolation in these towns has been carried out too imperfectly to give any value to their returns. Taking the 30 remaining large towns we find that 19 of these immediately after adopting notification, &c., commenced to increase their numbers of notified cases. The suggestion that the epidemic prevalence of scarlet fever is characterised by periodicity is negatived by the fact that these towns came under notification, &c., at varying periods. Amongst the towns and cities which did not yield an *immediate* increase London comes first. In the registration County of London there were notified, in 1890, 15,330 cases of this disease. There was a fall the following year to 11,398 cases. But the proof is absolute that the hospitals of the Metropolitan Asylums Board cannot be credited with this temporary improvement in the fact that the cases had mounted up in 1892 to the somewhat startling number of 27,093, and the year following to the enormous number of 36,901.

Other exceptions to the general rule of immediate increase in the number of notified cases on the adoption of notification, &c., are Bradford, with from 1881 to 1887 (inclusive) the following figures: 424, 408, 352, 493, 786, 1118, and 1308; Nottingham, from 1883 to 1889 (inclusive), 428, 384, 390, 351, 615, 643, and 1047; Hull, from 1890 to 1897 (inclusive), 377, 305, 497, 769, 744, 1062 1454, and 1495; Sunderland, from 1886 to 1890 (inclusive). 328 270, 506, 751, and 921; Derby, from 1890 to 1894 (inclusive), 346, 318, 470, 501, and 513; Plymouth. from 1889 to 1892 (inclusive), 470, 352, 239 and 1264 Finally, Wolverhampton, which from 1890 to 1894 (inclusive) had 500, 419, 242, 623, and 1096 cases. I am certain, Sirs, that the significance of figures such as these will not be lost on the readers of your valuable journal. They demonstrate plainly that the pest houses miscalled isolation hospitals are, regarded as preventive institutions, a delusion and a snare, a mockery which puts us as men trained in scientific pursuits to shame. If the sanitarian refuses to look this question squarely in the face depend upon it the economist will do it for him and that speedily, and it will be a day of humiliation for the former when this comes to pass.

Dr. A. J. Tonkin wishes me to explain why the number of notified cases diminished in Bolton during the years 1889 to 1894 (inclusive). It may have been for the same reason that the fall in 1896 in Nottingham followed the highest percentage of removals—namely, that the people of Bolton were learning by experience what the people of Nottingham were being taught by the sanitary authority—i.e., that hospital-treated cases could not be received back home with any degree of safety, the wisdom of sending such patients into the rural districts (where they would most certainly establish new centres of infection) being recognised. But if, for the purposes of argument, it be granted that "isolation" (strange misnomer!) was the cause, how comes it that the preventive institution which had reduced the number of cases in 1894 to 267 could not prevent the increase in 1895 to 495, in 1896 to 816, and in 1899 to 1226 cases? Again, if the reduction in 1896 in Nottingham was the result of the high percentage of removals the previous year, how does it happen that the high removal percentages of 1896 (86) and 1897 (90) did *not* prevent the enormous increase in 1899 to 2580 cases? Surely the increase from 517 (1897) to 931 (1898) and 2580 (1899) is a strange harvest for a preventive institution to reap!

To turn to a city in which Dr. Tonkin is peculiarly interested—the city of Manchester—there was a decided fall in the number of notified cases in that city in the years 1897-98, but your correspondent would hardly credit "isolation" with this passing improvement seeing that, from her earliest experience of notification, &c., Manchester had steadily increased her annual number of notified cases up to that period. Here are her figures.

Year.	Cases notified.	Percentage of Removals.
1891	1138	61·9
1892	1671	58·8
1893	2031	58·3
1894	2230	66·0
1895	2302	71·3
1896	2387	73·9
1897	1790	79·7
1898	897	73·1
1899	1461	75·0

Compare Manchester with her suburb, Gorton, and we shall find that a high percentage of removals is but a broken reed at best.

In his annual report (1898) Mr. A. W. Martin indicated pretty clearly to what, in his judgment, must be attributed the spread of scarlet fever. Gorton, with its exclusively working-class population, is compared with 12 of the large towns and Manchester. His words are:—"Out of each 1000 of the population the following numbers of scarlet fever cases occurred: average of five years, 1892-96, 12 notification towns, 4·43; Manchester, 4·05; Gorton, 3 3. The 12 notification towns and Manchester remove over 50 per cent. of their cases. Gorton 15 to 20 per cent."

Dr. Tonkin thinks that I am accusing him of unworthy motives when I suggest that he should have carried the upward curve for Nottingham (1899) to 2580 instead of leaving it at the point 1500. Not so. I passed lightly over the omission because I saw, in the first place, that he was unable *without nearly doubling the size of his chart* to get the splendid (!) results achieved by this city into it; and I had another reason which Dr. Tonkin may or may not appreciate: I thought I recognised in your correspondent a fair-minded opponent whom it would have gone "against the grain" to treat with undue severity. In the same spirit I pass over his observations about return cases, contenting myself with the remark that the accepted definition of a "return" case is "a case arising *in the home* to which a discharged patient has returned within three weeks of such return." Dr. Tonkin has joined issue with me in the judgment I have passed on this absurd definition when he claims that cases which arise through contact with discharged patients elsewhere than in the home should be classified as "return" cases.

In conclusion, Sirs, I should like to call attention to a cognate question of supreme importance to the people of this country—What is the explanation of the extraordinary prevalence of diphtheria at the present time? What baleful part is being played by the isolation hospitals in this matter? Last year in the registration county of London there were notified 13,711 cases of diphtheria. In Leicester the number of cases largely exceeded the number of scarlet fever cases. Is the explanation to be found in the *protracted infectivity* of hospital-treated cases to which I have frequently called attention? It would seem so from a case to which the medical officer of health (London) calls special attention. "A remarkable instance was that of a child who had been discharged from the hospital in August. Her mother contracted diphtheria in October and the child being sent to her father he also caught the disease. Later she went to stay with relatives in Fulham and her cousin got diphtheria. A visit to her uncle and aunt at Kingston was equally unfortunate, for both those relatives fell victims to the disease." Is this at all like anything we see in private practice?

I am, Sirs, yours faithfully,

Nottingham, Jan. 12th, 1901. EDWARD DEAN MARRIOTT.

THE SALE OF DRUGS UNDER THE PHARMACY ACTS.

To the Editors of THE LANCET.

SIRS,—It is my duty to inform you that a joint meeting of the Glasgow Southern Medical Society, the Glasgow and West of Scotland Branch of the British Medical Association, and the Glasgow Eastern Medical Society was held in

Glasgow on Jan. 23rd, 1901, to consider the action of the General Medical Council in their recent decision respecting the sale of drugs and poisons by persons not qualified to act as pharmaceutical assistants under the Pharmacy Acts. The following resolutions were adopted:—

That this meeting, having considered the recent circumstances of the action of the General Medical Council, is of opinion (1) that a written representation be made to that Council that their recent decision is, in the opinion of this meeting, unwarrantable in terms of the indictment and interferes with the rights and privileges of the profession as embodied in the Medical and Pharmacy Acts: and (2) that a committee of this meeting be appointed to oppose the Pharmacy Act (Amendment) Bill before the coming session of Parliament and to call the attention of the licensing bodies and the universities thereto.

There were reporters present at the meeting and a fairly full and accurate report of the proceedings will be found in the Glasgow daily papers of Jan. 24th, 1901.

I am, Sirs, yours faithfully,
AND. WAUCHOPE.
Editorial Secretary, Glasgow Southern Medical Society.
Crown-street, Glasgow, Jan. 26th, 1901.

"WHAT IS 'COGNAC BRANDY'?"

To the Editors of THE LANCET.

SIRS,—Unwilling as we naturally are to encroach upon your space at such a time as the present, we yet trust that you will give us an early opportunity of replying to certain remarks which appeared in THE LANCET of Jan. 26th that are calculated to unduly prejudice the British public against the trade in cognac brandy in general and against our two firms in particular. We refer to your notes regarding a case heard on Jan. 14th in Dublin before the Lord Chief Justice and a special jury, in the course of which one of the defendants is reported to have said that such a thing as cognac made from Cognac grapes exclusively did not exist on the market.

Cognac, as everyone knows, is a town, not a vineyard, and the Cognac district has always been recognised as comprising the departments of the Charente and Charente Inférieure, a geographical, not a qualitative distinction. Assuming, therefore, that by "Cognac grapes" the defendant meant grapes grown in the Cognac district, we have no hesitation in stating that he betrayed, to say the least of it, a lamentable ignorance of the subject with which he was dealing. In proof of this we have only to point to the fact that there are now being offered on the market brandies of the last vintage, the pure produce of the Charente, which cost the English importers less than did the vintage of 1878 and many others of the ante-phylloxera days. His allegation that our brandies were made in the same way as his own we can afford to leave to the opinion of the public who are the best judges of fine quality.

No fear need be entertained on the score of the supply of good cognac brandy at moderate prices, for the vineyards have been extensively replanted and the stocks of pure brandy in the hands of the Cognac shippers are larger than they have been at any time since the visitation of the district by the phylloxera.

We are, Sirs, your obedient servants,
JAS. HENNESSY AND CO.
Cognac, Jan. 28th, 1901. MARTELL AND CO.

"THE EFFICIENCY OF LIQUID EXTRACT OF ERGOT."

To the Editors of THE LANCET.

SIRS,—I think most practitioners will agree with Mr. J. C. McWalter that the ordinary liquid extract of ergot is a most unsatisfactory preparation. I have used it largely, have tried many preparations and have found them all inert. On the other hand, I think if there is an established fact in medicine it is the power of ergotine to arrest hæmorrhage. It matters not whence the hæmorrhage proceeds, from the uterus, the stomach, the lungs, or the nostrils, I have found it equally efficacious. Ergot and uterus are like hand and glove and need no illustration. In profuse epistaxis and hæmoptysis there is no remedy, I think, equal to a hypodermic injection of ergotine. Time and again I have seen this, and that, too, after all other methods of treatment had failed. The objection that abscess is very apt to follow the subcutaneous treatment is not of much weight. Only once have I seen this result and that was in a case of post-partum hæmorrhage, when I had to trust to the nurse to perform the operation. She simply inserted the nozzle of the syringe under the skin instead of plunging it boldly into the muscular structure. If this latter instruction is observed I believe bad effects will be rarely seen. I agree with all that Mr. McWalter says, and only add that the sooner the preparation called liquid extract of ergot is banished from the Pharmacopœia the better.

I am, Sirs, yours faithfully,
J. BRISBANE, M.D. Glasg.
St. John's Wood-road, N.W., Jan. 28th, 1901.

"THE EXAMINATIONS FOR THE SWISS FEDERAL DIPLOMA."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Jan. 26th, p. 282, a letter appears from Dr. Edward H. Douty describing the above examinations in rather lurid colouring. Amongst other things he says: "I am the first Englishman to obtain the diploma under these regulations. It is 10 years since they were enforced, and meanwhile only one Englishman has attempted, and no one has succeeded, in obtaining the diploma." This might lead your readers to assume that Dr. Douty is the only English practitioner who has passed successfully the Swiss medical examinations. This is not the case. I myself obtained the Swiss diploma by passing the full curriculum for qualified practitioners in May, 1891, and there are half a dozen others who have done the same. In his success Dr. Douty forgot his colleagues at the moment of penning his communication to you.

I am, Sirs, yours faithfully,
TUCKER WISE,
Montreux. Swiss Federal Diploma.

PROPOSED ALTERATION IN THE MANAGEMENT OF NEW YORK CITY HOSPITALS.

(FROM A CORRESPONDENT.)

THE hospitals in the United States are for the most part administered very differently from similar institutions in Great Britain. In the first instance, it must be understood that, as a rule, the hospitals throughout this country are not endowed and are consequently either dependent upon the municipalities of the towns in which they are situated for the necessary funds to support them or derive their income from paying patients. There are few entirely charitable hospitals in the United States. The large majority of them charge any sum from five dollars (£1) weekly to 50 or 60 dollars (£10 or £12) weekly for the privilege of being an inmate and of receiving medical or surgical attendance. In almost all the larger cities, however, there are one or two hospitals the expenses of which are borne by the citizens. In New York, for example, the Bellevue Hospital, with its subsidiary hospitals, Gouveneur, Haarlem, and Fordham Hospitals, and the Emergency Hospital for Women, are a part of the Department of Public Charities, for the administration of which a grant is made by the city each year. If the money thus set aside were wholly devoted to the best interests of these institutions and of the patients therein this system would probably work fairly well. Unfortunately, it is contended by the opponents of this system that this is not the case and that politics play an important part in the management of the New York city hospitals.

Some time ago Mr. Theodore Roosevelt, the energetic Governor of New York State, appointed a commission, called the Charter Revision Commission, whose duty it was to investigate closely and to propose reforms where considered necessary in the several charters of New York city. This commission has recently completed its session and has published a voluminous report detailing reforms which it has judged would be of benefit to the city at large. Among the proposed amendments is one dealing with the control of the city hospitals. The amendment in question provides that on Feb. 1st, 1902, the control and management of Bellevue Hospital, including its subsidiary institutions, Gouveneur, Haarlem, and Fordham Hospitals, and the Emergency Hospital for Women, shall be taken from the Department of

Public Charities and be vested in a board of trustees appointed by the mayor. If this proposed amendment becomes law Bellevue and its branch hospitals will be brought under the same system of trustee management which now prevails in private hospitals in this and other cities as well as in the public hospitals of Boston and Cincinnati. This plan, which has been in force in Boston and Cincinnati for between 35 and 40 years, has been found to answer excellently. The hospitals in both the instances mentioned are models of their kind and will compare favourably with the best private hospitals in any American city. Their buildings are up-to-date and well equipped with all modern appliances for the investigation and treatment of disease, and they maintain a high standard of efficiency and discipline. In other large cities, as Philadelphia, Chicago, St. Louis, and San Francisco, the public hospitals are managed, as in New York, by the Department of Public Charities, which management changes with each change of the city administration. The hospitals being a part of a city department are regarded as belonging to the political party in power and form an important share in the distribution of party patronage. It may be asked, What would be the special gain to Bellevue Hospital from the proposed change of management? This question is so well answered by a writer in the Sunday edition of the *New York Sun* of Dec. 2nd, 1900, that I cannot do better than quote his words:—

> It will gain in the first place all that comes from a permanent and stable form of administration. Had Bellevue been governed by an intelligent board of trustees during the past 30 or 40 years, we should not have now the heterogeneous collection of buildings wholly unrelated to each other, and of widely differing styles of architecture, that bear the name of Bellevue Hospital. Nor would the Haarlem Hospital be occupying an old frame dwelling-house which was never intended for the purposes of a hospital, and which has been for years totally inadequate to the demands made upon it. Nor would Gouveneur Hospital be striving in vain to get into its new building—a building the construction of which was authorised in 1895, and which was completed more than a year ago. During the same period of time Boston and Cincinnati have erected modern hospitals suited in every way to the purposes for which they were built, and yet there has been no complaint on the part of the taxpayers of these cities, for they have before them the evidence that their money has been wisely and economically spent.
>
> The second gain that may be hoped for from the proposed change will be the taking of Bellevue out of politics. All good citizens will surely agree that politics should have no place in the administration of an institution devoted to the care of the sick. That such a self-evident proposition has not been perceived, or at all events not been acted upon, before in New York, has probably been due to the fact that our public hospitals have always been a part of a great city department and as such have been naturally administered with the other institutions in the department by an official of the party in power. With the hospital taken out of the city department and provided with its own system of control and administration, running along smoothly from year to year, it will attract less and less the attention of the politicians. It may not come in the first year or the second year or the third, but surely in time the persons selected to serve on the board of trustees will be chosen because of their personal fitness for the place and not because of their party affiliations.
>
> In the third place, Bellevue will be the gainer because it will be made a specific city interest, independent of the other institutions in the Department of Public Charities. The patients in Bellevue are not paupers; they are for the most part working men and working women who by reason of illness or injury are temporarily prevented from earning a living. They cannot afford medical care and nursing at their own homes, and go to their only place of refuge, the public hospital. And it is only the part of a wise policy on the part of the city to make them well again and self-supporting as soon as possible. It is not just, it is not humane, to class them with paupers and thus to rob them of their self-respect. Bellevue has too long been considered in the public mind as a paupers' hospital. Let us hope that this stigma will be removed under the new form of administration.

The advocates of the suggested alteration wish it to be distinctly apprehended that the measure has no political significance whatever and that no fault can be found with the attitude of the present Commissioner of Charities. It is the system and not the man which is to blame. At the same time, it is keenly felt that radical changes in hospital management in New York are clearly indicated and it is earnestly hoped that the proposals tending in this direction may become law. The point is a moot one as to whether the British system of absolutely free hospitals or the method of hospital management chiefly prevailing here, in which all patients, except in a few institutions, pay for their board and medical attendance, is the best. Undoubtedly the British system has a tendency to pauperise, while, on the other hand, the great majority of American hospitals are closed to those who cannot afford to defray the expenses of their keep and attendance. A judicious mingling of the two methods might evolve the ideal hospital. Until, however, that happy day arrives the only thing to be done is gradually to improve upon the present system, and I feel convinced that the proposal of the commission in New York is a step in the right direction.

Jan. 22nd.

CERTAIN ASPECTS OF CONSCRIPTION.

(FROM A CORRESPONDENT.)

[RECENT events have brought into prominence the question as to whether conscription will be rendered necessary in this country if Britain is to hold her own in the world. A pamphlet on Army Reform by Lieutenant Colonel Hime[1] attempts to show that conscription need not take the form usually suggested and that it might conceivably be carried out without injury to the worldly prospects of those affected by it. Events which have happened since the pamphlet was published have proved that misgivings as to the state of the British forces which at the time were considered pessimistic have been more than realised. These circumstances have moved a valued correspondent to address us upon certain aspects of conscription. We are not prepared at the present moment to endorse or controvert the views either of Lieutenant-Colonel Hime or of the writer of the article which follows. But as it is good that medical men, the guardians of the national health, should give the whole subject of conscription their attention, we put before our readers some apposite food for reflection.—ED. L.]

The difficulty of obtaining recruits for the army is no new one in England. Formerly large bounties were paid on enlistment. In the year 1775 the Minister of War found that he could not raise the army to its proper strength. In 1804 the bounty rose to 16 guineas, and although the prisons and the hulks were emptied to supply men to serve, yet in 1806 the army was much below the proper establishment. At that time Mr. Wyndham declared that Parliament would have to decide how they could ensure to this country what unquestionably it had never previously had—an unfailing supply of regular soldiers. Even now in the year 1901 in a time of war it does not seem to be possible to obtain a sufficient number of recruits to serve in the army. One thing is quite certain. Criminals should not be enlisted. At the beginning of the present war one or two of the London stipendiary magistrates were inclined to deal leniently with prisoners who promised to join the army. It is extremely bad for a regiment to have such recruits. It should not be forgotten that the conditions of the service have greatly altered since the beginning of the last century. At that time the method of enforcing discipline both in the army and in the navy was characterised by a severity which appears to-day to be absolutely brutal. There are, for instance, in some of Marryat's novels records of incidents which are really horrible, but which were true pictures of events which were formerly of daily occurrence.

At the present time whilst the conditions of life in the services have vastly changed for the better there is no less difficulty in regard to recruiting. How is this to be accounted for? Colonel Hime unhesitatingly says that it is due to the present industrial prosperity and he agrees with M. Comte, the Positivist philosopher, that in the continuous decline of the military spirit and in the gradual ascendancy of the industrial spirit we see the repugnance of modern society to a military life and that for this reason compulsory service becomes more and more necessary. As the military spirit declines the industrial spirit increases, wages rise, and the condition of the labouring classes improves. The increase in wages and the dislike for discipline cause a falling off in the relative number of men who are willing to serve in the army. These causes were working steadily during the latter part of the last century. The only way to overcome the difficulty has been from time to time to increase the inducements to enlist. But at the present time the cost of the army is very considerable and the increase in the expense is not only due to some addition to the pay but to improvements in the food, in the clothing, in the bedding, in the barracks, and to payments made for good conduct and for the expenses of recreation rooms. In spite of recent improvements the life of a soldier is not sufficiently attractive to draw anything like the full number of the men required; yet, roughly speaking, the army

[1] Army Reform, a Question for the People. By Lieutenant-Colonel Henry H. L. Hime, late Royal Artillery. London: Edward Stanford, 26 and 27, Cockspur-street, Charing-cross, S.W. Price 1s.

estimates have about doubled since the year 1853. Should the expenses of the army go on increasing at this rate it seems certain that the country would be unable to stand the financial strain—"our entire revenue applied exclusively to military purposes," according to the late Professor Cairns, "would not suffice for the drain." Our present system had proved to be a failure at the time that Colonel Hime's pamphlet was written. "We have been obliged," Lord Lansdowne had already confessed, "to fill up battalions which ought to be at home with young soldiers and send them to the Mediterranean, thus filling our garrison there with troops unfit to take the field."

Colonel Hime gives an account of the various periods of service for which enlistment has taken place. He classifies them into four divisions: (1) life service; (2) long service (for example, 21 years); (3) medium service (say, seven years); and (4) short service (three years). In the case of life service a man had no anxiety in regard to his future, but life service was objectionable from a medical point of view; the period of life during which a man is a really effective soldier falls far short of the ordinary span of life. Long service was found to be very expensive and it made no provision for a reserve. From a medical point of view it seems that the term of seven years is the best. During this period the death-rate from ordinary causes is less amongst soldiers than it is amongst the male civil population of healthy districts in England and Wales. At the end of seven years' service the death-rate amongst soldiers increases more rapidly than does that of the male civil population. The question arises, What effect has a seven years' service on the man who serves for that period? It is true that the earlier and best years of his life are those in which a man most easily establishes his position in the world and his after-career usually depends on this. When a soldier leaves the army at 23 or 24 without pension he finds that his contemporaries have passed him in the industrial race. Now, should he leave without further liability to military service it may be reasonably argued that the Government ought to give him any suitable employment which can be found for him, but if he should go into the reserve it would be unwise to employ him in a Government office; it would be unwise to man the postal or the telegraph service or the arsenals with men who would be called out in case of an invasion, for at such a time telegraph clerks and railway porters could not be spared to leave the duties with which they are acquainted at the exact period at which their services would be most required. The method recommended by Colonel Hime for getting over the present *impasse* is that two distinct armies should be formed—a foreign army and a home army. In the case of the foreign army the period of enlistment should be either for long or for medium service, but in the case of the home service it need not be sufficiently long to injure a man's career as a civilian.

What is the least period of training which will serve to turn a civilian into an efficient soldier? Would one year's service if properly spent suffice to train an infantry soldier? With the present system of education Colonel Himes says emphatically it would not. But instruction could be given at high pressure and considerable modification could well be made in the present system. In the case of a one year's service all the available time should be spent in shooting, in route-marching, and in light infantry drill. Elaborate drill should be superseded by the few and simple movements which are required in modern war. No courses in the "polite accomplishments" are necessary, and the gymnastics taught would be confined to their elements. Now, from a medical point of view a year spent in drill in shooting, and in gymnastics would be certainly an advantage to most Englishmen. This course of instruction, if it were continuous and practical and confined to essentials, and if, moreover, as would be undoubtedly the case, men of a higher intellectual calibre than that of the present recruits were enlisted, would make good soldiers, Colonel Hime maintains, in one year. Artillery and cavalry soldiers would need, however, 18 months at the least. The infantry of the home army, under the system suggested, would consist of short-service soldiers who would only be sent out of the country in time of war.

The argument up to this point is briefly as follows: There is an insufficient supply of men; if men are to be attracted by increase of pay the cost will be ruinous. Now, what is to be done? What are the alternatives? There are two. One is that we should do without an efficient army, in which case the fate of other nations will be ours, and probably at no distant date. We should follow in the wake of Persia, of Greece, and of Rome. If the people are content to renounce our Empire our military defects may be disregarded. The other alternative is conscription. The "liberty of the subject" would be no more endangered by compulsory military service than it has been by compulsory education. No one would suggest that it was prudent to wait for the outbreak of a great war before making the necessary changes in the army.

Several modifications of conscription have been tried, but reference need only be made to universal conscription with substitution[2] or with dotation,[3] limited conscription,[4] and universal conscription. All systems except universal conscription are bad because they are founded on the theory that some men are bound to defend their country and some are not. Universal liability to military service should be enforced. This would give a first line of defence and large reserves at a less cost than that of the present home army, it would absorb the present auxiliary forces and fuse the home army into one harmonious whole.

It is suggested that it would be absolutely necessary to the success of the scheme to abolish the auxiliary forces. When England was threatened with invasion by Napoleon I. the English Government tried to put in force the ballot for the militia and passed a recruiting law, but they unwisely excepted volunteers from the provisions of the Act. The effect produced was summed up by Mr. Wyndham in the House of Commons: "Mr. Addington," he said, "has not only not provided an army, but has rendered it impossible that an army should be provided," for the volunteer system had either by design or mistake locked up 400,000 men of the active population of the country. The defences of England could not be entrusted to volunteers. Discipline is by no means a military fiction, and it is, as Mill pointed out, acquired only by practice. Military service is not, and ought not to be thought to be, derogatory to a "free-born citizen," nor would submission to military rule be injurious to the moral and intellectual development to those affected. These arguments are of great force. The training which would be obtained by young men during an impressionable part of their life—training both physicial and mental—would be of the greatest advantage to them in after-life. The power of being able to walk well, the training of the eye, of the hand, and of the intellect required in becoming a good shot—these are things which would be of special benefit to the middle and to the lower classes. The life to healthy young men would be by no means an unpleasant one, and they would gain not only in muscular power but also in mental training and obtain experience which would be of use to them for the remainder of their lives. Doubtless many of them would afterwards look back upon their year of military service as the happiest time they had ever spent. There is no doubt also that discipline, the want of which is so sadly in evidence amongst many of the rising generation, would be of the greatest possible service, not only to those brought directly under its influence, but also to all the people with whom those who have been affected by it come into contact in after-life. When universal conscription has been introduced no man below a certain age who has not creditably served his year of military service should be admitted to the privileges of English citizenship. No man who has not made himself capable of defending his country has any moral right to have a voice in its government.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Loss of Life in India from Wild Animals.—The New Year's Honours for Plague-workers.—The Return of Lumsden's Horse from South Africa.—The Plague Epidemic: Recrudescence in Bombay City and Threatenings in Calcutta.—Jail Appointments in India.

A RECENT report shows that 2966 people died last year from the attacks of wild beasts and no less than 24,621 people from snake-bites. The Bengal Presidency is by far the chief sufferer, as 1632 people were killed by wild animals and

[2] Under this system a man is allowed to pay another to serve in his stead.

[3] Under this system a man can make a payment instead of serving.

[4] This system has been adopted in England. The classes affected have been imprisoned debtors (1695-1702), criminals (1702), and paupers (1703).

12,220 died from snake-bites. The large number of snake-bites is partly attributed to floods which drove the snakes to higher ground where the natives dwelt. The numbers killed by the different wild animals are as follows: 899 by tigers, 338 by wolves (chiefly in the North-West Provinces), 327 by leopards, 95 by bears, 40 by elephants, 27 by hyenas, and 1230 by other animals, chiefly jackals and crocodiles. In addition to human beings no less than 100,000 head of cattle were killed, of which 37,986 were killed by leopards but only 9449 by snakes. There is, of course, a constant warfare between man and these wild animals, and notwithstanding that 1570 tigers, 4548 leopards, 2317 wolves, 776 hyenas, and 94,548 snakes were killed during the year the battle inclines in favour of the wild beasts. There is an impression in many places that some of these deaths ought really to be put down to murder. When a native wants to get rid of an inconvenient relative it is very easy in some places to put down his disappearance to a wild animal.

The New Year's Honours' list for India contains but few names of plague-workers. Amongst the many who have borne the brunt of the epidemic during the past year I note but five who have been officially rewarded. The Companionship of the Star of India is given to Major John Crimmin, V.C., I.M.S., port health officer, Bombay, and the Kaiser-i-Hind Gold Medal to Lieutenant-Colonel Wilkins, I.M.S., late special medical officer of plague operations in Bombay city. The Kaiser-i-Hind Silver Medal is given to Miss Alice Cathorm, M.B., now at Poona; to Lieutenant-Colonel Sutherland, late plague officer, now in Bombay; and to Miss Ellen Smithi, nursing sister, of Bombay.

The Volunteeer contingent from India (Lumsden's Horse) have just returned. On their departure I described their excellent physique and suitability for the particular work. It is satisfactory to find that their casualties have been very few and that sickness has been almost absent among them. Out of 250 men only two have died from sickness and only six deaths occurred altogether. The total casualties were only 24. These figures show how good their physique was and they also show how well they have been cared for and treated.

The plague returns for the week throughout India are very discouraging. The mortality rose only from 2267 to 2298, but there has been a large increase in Bombay city (from 114 to 149) and in Western Bengal. The figures are: Bengal 1374 (Patna 791, Saran 323, Monghyr 165, Gaya 93, and Calcutta 50); Bombay Presidency 421 (Bombay city 149), Madras Presidency 15, the Punjab 7, and Mysore State 431. Private accounts say that in Patna there is a panic developing and that the people are flying from the place. The disease still lingers in the Punjab, 17 cases being reported in the Gurdaspur district. In Calcutta there were distinct signs of a recrudescence, many more plague deaths having occurred since the last returns were made up. The figures include so-called "suspicious deaths," but there is not much doubt that most of them are due to plague.

The prospects of officers joining the Jail Department have not been very promising and this service has become unpopular. Of the 40 central jails in India 30 are under the superintendence of officers of the Indian Medical Service. The permission to engage in private practice is not worth very much, because not only is the work becoming more and more harassing but the distance at which the jails are, as a rule, situated from large towns militates against the chances of an officer acquiring much private practice. The chances, again, of becoming an inspector-general are also remote because there are only five of these appointments in the country. I understand that certain proposals are on foot for bettering the prospects of this department.

Jan. 5th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Arsenical Poisoning in Liverpool.

THE public analysts (Professor J. Campbell Brown and Mr. W. Collingwood Williams), in pursuance of a resolution of the Health Committee, reported in reference to the recent outbreak of arsenical poisoning somewhat in the following terms. That from Nov. 27th, 1900, to Jan. 11th, 1901, and including also a few samples delivered since, the analyses of which were completed at the date of the report, 381 samples submitted by the city officials had been specially examined with the view of detecting arsenic and of distinguishing between a slight contamination and a substantial quantity of arsenic. Of 312 samples of beer 29 were seriously and 28 slightly contaminated; of five samples of brewing beer two were seriously contaminated; one sample of malt had a small quantity of arsenical smoke on the surface; of three samples of yeast all contained a slight incidental trace of arsenic; of 60 samples of confectionery, jam, marmalade, preserved fruits, syrups, and a few miscellaneous samples, it was satisfactory to find that none contained any trace of arsenical contamination. In the arsenical beer from all sources examined in the laboratory the most common proportion was a figure not far from one-tenth of a grain per gallon, more or less; some contained two or three times as much, some not much more than half that proportion. A few samples contained nearly three-fourths of a grain, more or less, per gallon, and one sample contained one and a half grains per gallon. Within 36 hours of the time when it was first known in Liverpool that arsenical sugar was the source of arsenic in beer samples of glucose and of beer were in the hands of the analysts; and within a few days such numbers of samples were being poured into the laboratory that it was at once evident that the emergency must necessarily be treated in a special manner by the medical officer of health, resulting in the destruction of thousands of gallons of suspected arsenical beer and the withdrawal from sale by the publicans and brewers of all beer objected to, whether actually poisonous or not, if it contained arsenic. Thousands of gallons of beer were thus removed from sale before the analysts could even have gone through the process of writing preliminary reports. Afterwards, when guilty knowledge could, perhaps, have been proved and proceedings before the magistrates taken with a likelihood of success, larger samples were purchased with all formalities required by the Acts. In these larger samples, so far as the city was concerned, arsenic was generally absent or in too slight a quantity to be estimated or to be of any sanitary importance. The use of arsenical sugar in Liverpool was now proved to be extinct. From Dec. 17th to Dec. 22nd, of 23 samples of beer examined none contained any substantial trace of arsenic. From Dec. 24th to Dec. 29th, of four samples of beer none contained any arsenic, but one sample of malt contained a small quantity. From Dec. 31st to Jan. 11th of 20 samples of beer none contained any substantial trace of arsenic, and of three samples of yeast all were very slightly contaminated with a trace too slight to be weighed.

Liverpool School of Tropical Medicine.

The annual dinner of the Royal Southern Hospital has been fixed for Feb. 12th and it has been decided to hold the dinner in connexion with the School of Tropical Medicine, which institution is indebted to the Royal Southern Hospital for the use of a special ward for the treatment of tropical diseases and is officially connected with that hospital. The dinner will be made the occasion publicly to acknowledge the services rendered by the School of Tropical Medicine, especially in the matter of sending important medical research expeditions to the tropics. The chair will be occupied by the chairman of the school (Mr. Alfred L. Jones), and the guest of the evening will be the Duke of Northumberland, K.G., who has taken an active interest in the work of the school. The Earl of Derby, K.G., and the Lord Mayor have also accepted invitations to the dinner.

The late Dr. Walter Myers.

A letter of sympathy has been received by the authorities of the Liverpool School of Tropical Medicine from the Secretary of State for the Colonies (the Right Hon. Joseph Chamberlain) in reference to the lamented death of Dr. Walter Myers, who, as stated in THE LANCET, was despatched in June, 1900, to Pará in Brazil for the purpose of investigating the origin of yellow fever. Mr. Chamberlain, in his letter to Mr. Alfred Jones, the chairman of the school, stated that "he had received with the greatest regret the news of the death of Dr. Myers in the service of humanity to which he had devoted himself. It will be a great loss to the Liverpool School and to the science of tropical diseases." Mr. Chamberlain also expressed in his letter his deepest sympathy with the family of the late Dr. Myers.

The David Lewis Northern Hospital.

The annual meeting of the supporters of the Northern Hospital was held in the town hall under the presidency of the Lord Mayor. The number of patients attended to during

the year had been 1855 in-patients and 8117 out-patients, involving 25 993 attendances. The ordinary expenditure had been £7956 odd, as against £7305 odd in 1899. There is a deficit of £5034, as against £3761 in 1899. The receipts from all sources had been £6683 8*s*. 7*d*. The sum of £1690 had been received from the Hospital Sunday and Saturday Fund, without which it would have been impossible to have done the work which had been accomplished. In future about £10,000 a year will be required to carry on the work of the hospital. It was decided to change the name of the institution to "the David Lewis Northern Hospital" in commemoration of the beneficent donor of the new hospital.

Notification of Phthisis.

At the recent meeting of the Health Committee the medical officer of health (Dr. E. W. Hope) was instructed to report on the institution of a system of voluntary notification of cases of phthisis, with payment to medical men of a small fee for each case notified.

Liverpool Royal Infirmary.

Dr. T. R. Glynn, the senior physician to the infirmary, retires from the active honorary staff in accordance with the age-limit of service. Dr. Glynn's retirement will create a void at the infirmary which it will be difficult to replace.

Jan. 30th.

WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Fees payable to Workhouse Medical Officers.

THERE has of late years been a disposition upon the part of public bodies to abolish the payment of officials by fees and to require that a fixed salary shall be an inclusive payment for all duties performed. When the Merthyr Board of Guardians recently increased the salary of Mr. J. L. W. Ward, the medical officer of the workhouse, a stipulation was made that the fees which he had formerly received should merge in his salary; the Local Government Board, however, will not sanction this arrangement in its entirety and insist that he shall still be paid by fees for vaccinations performed at the workhouse.

Hospital Accommodation.

A movement has been started to establish a cottage hospital at Treharris, a large colliery district adjoining Merthyr. The paucity of such institutions in the South Wales coal-fields has often been remarked. There is a general hospital at Merthyr and there are cottage hospitals at Aberdare and at Mountain Ash, in the Aberdare valley, and an accident hospital with 10 beds at Porth, in the Rhondda valley, but at Pontypridd, where there is a population of over 40,000 persons, no such institution exists, though the district council only a few months ago considered the desirability of erecting one and supporting it out of the rates, a course which was last year adopted at Barry.

Adulteration of Milk.

When retail milk-dealers are convicted for selling adulterated milk a common defence put forward is that the milk was sold as it was received from the farmer or milk-factor. When this plea was raised at Cardiff Police-court three weeks ago the stipendiary magistrate expressed the opinion that the wholesale dealers should also be proceeded against. A Somerset farmer accordingly appeared before the bench last week and pleaded guilty to the charge of adulterating two samples of milk which had been taken at the railway station. He was fined £15 in each case.

Sewage Disposal.

The appearance of a railway map of the district which lies between Newport and Cardiff on the south and Abergavenny and Merthyr on the north very much resembles the diagram of a gridiron. There are three lines running nearly east and west and these are crossed almost at right angles by numerous other lines terminating at the coast. These latter lines really indicate valleys which extend northwards. The question of dealing with the sewage of the townships which have been rapidly growing up along these valleys has for some time been prominently before those concerned with their sanitary administration. Until quite recently the construction of a main outfall sewer or sewers seemed to be the only practicable solution of the question, for the narrowness of some of the valleys and the difficulty there is in obtaining suitable land has almost precluded the possibility of treatment by irrigation; but since the successful installation elsewhere of septic tanks and bacterial filters this method of treatment is being put forward as the most desirable, and it is even said that the huge tips of refuse from the collieries will make excellent "contact beds." One great disadvantage attending the construction of main trunk outfalls discharging into the Bristol Channel is connected with the subsidences which occur all over the coal-fields and which make it possible for a sewer originally laid with an excellent fall to become level or even to fall the reverse way. The sanitary authorities governing the districts known collectively as the western valleys have after repeated conferences at last appointed an engineer to advise them as to the best scheme or schemes to be adopted either for the district as a whole or for individual localities.

Unsound Meat.

Cardiff is particularly well off in not having any private slaughter-houses, so that the difficulties attending the detection and seizure of unsound meat are very much less than they are in those towns which are not entirely dependent upon public abattoirs, but considerable vigilance is still required in order to prevent undesirable carcasses that have been slaughtered outside the borough being brought for sale within the town. Early in the present year a butcher exhibited for sale in one of the public markets the dressed carcass of a bull which had been drowned. Fortunately a sanitary inspector detected its condition and the owner last week was fined £20 in addition to the court costs, with the alternative of two months' imprisonment. The stipendiary magistrate warned him that in the event of a second conviction for a similar offence he would be sent to prison without having the option of paying a fine.

Prosecution under the Public Health Act.

In spite of repeated prosecutions the inhabitants of the Rhondda valleys persist in defying the law with respect to the exposure in public places of infected persons. At the Porth Police-court last week a collier was fined £3 for travelling by train to North Wales a fortnight after he had been attacked with scarlet fever. During the hearing of the case it transpired that the man had been given by the sanitary inspector a printed form upon which had been filled in the earliest day upon which he could go out of doors—a date which was six weeks from the first appearance of the rash—so that the defendant was unable to plead the usual excuse that he did not know how long he ought to have stayed in the house.

Bath Western Dispensary.

The annual meeting of the subscribers of the Bath Western Dispensary was held on Jan. 23rd, under the presidency of the Rev. J. Stedman. The medical report stated that 1001 patients had been attended during 1900, including 302 patients visited at their homes. The financial statement was satisfactory and showed a favourable balance of £63. The thanks of the committee were given to Mr. J. Davies and Mr. G. E. Bloxam, the medical officers, for their work during the past 12 months.

The late Professor Alfred Hughes.

At a meeting of the executive committee of the Hughes Memorial Fund held at Cardiff on Jan. 18th, under the presidency of Dr. W. T. Edwards, it was reported that the subscriptions now amounted to £700.

Newton Abbot Hospital.

The annual meeting of the subscribers of the Newton Abbot (Devon) Hospital was held on Jan. 24th. The medical report for 1900 was very satisfactory and the financial statement showed that the income amounted to £1552 and the expenditure to £1390, leaving a favourable balance of £162. The committee decided upon an alteration in one of the rules in reference to the admission of out-patients as it was considered that this department was abused.

St. Columb Workhouse.

At a meeting of the St. Columb (Cornwall) Board of Guardians held on Jan. 24th Mr. Preston Thomas, of the Local Government Board, reported that on Jan. 22nd he had visited the workhouse and found a scarlet fever patient being illegally nursed by an inmate. The chairman of the visiting committee said they had no isolation hospital and

the workhouse nurse was not allowed to go to infectious cases.

University of Wales.

Lord Tredegar and Dr. Isambard Owen have been appointed life members of the Court of the University of Wales in succession to the late Marquess of Bute and the late Rev. Principal Edwards.

Bristol Royal Infirmary.

Mr. Alfred Robinson, J.P., has given a donation of £1000 towards the funds of the Bristol Royal Infirmary.

Health of Falmouth.

Dr. W. K. Bullmore, the medical officer of health of Falmouth, reports that during 1900 there were 272 births, equal to a rate of 22·3 per 1000. The deaths numbered 195, equal to a death-rate of 15·9 per 1000, the population of Falmouth being estimated at 12,665. Dr. Bullmore states that owing to the epidemic of typhoid fever in 1899 there were 1044 tests applied to drains, 419 intercepting traps laid, 707 defective sinks replaced, and various other sanitary improvements made. During the year 350 children were vaccinated and no prosecutions took place.

Jan. 28th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The late Dr. Stevenson Macadam.

By the death on Jan. 24th of Dr. Stevenson Macadam the School of Medicine at Surgeons' Hall, Edinburgh, has lost one of its oldest teachers. Dr. Macadam was born in 1829. After working at chemistry for some time in Glasgow Stevenson Macadam succeeded his brother John as assistant to Dr. George Wilson in Edinburgh when his brother obtained the appointment of professor of chemistry in the University of Melbourne. In 1855 he started classes specially for the pharmaceutical students in Princes-street, and when Dr. Wilson was appointed Professor of Technology in the University Macadam became Lecturer on Chemistry in the School of Medicine. At the close of last summer session Dr. Macadam completed 50 years as a lecturer, in 45 of which he had been an independent teacher. He held the degree of Doctor of Philosophy from the University of Giessen and was a Fellow of the Royal Society of Edinburgh. He was an original member of the Institute of Chemistry and of the Society of Chemical Industry. As a lecturer his style was lucid and interesting. His classes were always well attended. He was a keen sportsman as well as a splendid walker and good oar. He is survived by his widow, two sons, and two daughters.

Edinburgh Medical Missionary Society.

The annual meeting of the Edinburgh Medical Missionary Society was held on Jan. 24th, Professor A. R. Simpson presiding. The annual report referred to the death of their president, Sir Thomas Grainger Stewart, of Sir Douglas Maclagan and Dr. J. B. Fleming, two of their senior directors, and of Sir Thomas Clark. The report stated that as a result of their jubilee effort they had in hand a nucleus of £3000 with which to face the much needed extension of their premises in Edinburgh. The total number of cases dealt with at home was 9575 and 221 patients, women and children, had spent some time in Hawthornbrae Convalescent Home. The expenditure for the year had exceeded the income by some £1005. The directors, in view of the serious falling off in subscriptions, urged upon the public the necessity of an increased liberality so that the beneficent work of the society might not be curtailed. Subsequently the Rev. Dr. James A. Dyer, from Santalia, and Mr. D. D. Muir, from Manchuria, spoke. After the adoption of the report Dr. James Ritchie was appointed president of the society and the Rev. Dr. M. Murtrie vice-president. The Rev. Dr. Cameron Lees, the Rev. Professor A. R. S. Kennedy, Mr. Charles E. Green, Dr. Andrew Balfour, and Sir Archibald Campbell were added to the directorate.

Inter-Universities Conference at Aberdeen.

The annual conference of the delegates from the Students' Representative Councils of the four Scottish Universities was opened in the Debating Hall, Students' Union, Marischal College, Aberdeen, on Jan. 25th. In the absence of Principal Lang the students were welcomed by Professor Stephenson, the senior professor. The only point of interest from a medical point of view was a motion, which was unanimously adopted, that a representation be made in favour of the institution of a doctorate in surgery. The mover objected that under the new regulations the M.D. thesis must be written exclusively on a medical subject, and that the M.D. was no longer the all-round examination it used to be. The Ch.M. degree was not popular. Another motion which was passed unanimously was that the University authorities be petitioned to give preference to senior students at cliniques and to institute a double final in medicine where not already existing. In the course of Saturday's sitting Principal Lang, who had been absent on the previous day, welcomed the delegates in the name of the University.

Glasgow Royal Infirmary.

The reconstruction scheme continues to excite a considerable measure of criticism, the majority of the comments taking a hostile tone. Hitherto the voices of disapproval have been those of individuals without organisation, but during the past week there are signs of the opposition taking to itself a more definite shape and expressing itself in a campaign of protest. On Jan. 21st the Glasgow Institute of Architects addressed to the managers of the infirmary an open letter, in which it is stated that in the opinion of the institute the adopted plan will fail to give a building in conformity with the modern standards of hospital requirement. It is urged that the sketch plans issued to the competing architects are in many vital particulars inadequate and out-of-date, and that these faults are equally displayed in the selected design. The unanimous opinion of the institute is also advanced against the erection of a Jubilee block seven storeys high on the ground that such a building, on the site selected, will dwarf and irretrievably injure the appearance of the cathedral. And further, a protest is lodged against the action of the sub-committee in setting aside without any reason given the award of the professional assessor, Dr. Rowand Anderson, more especially as the decision against his recommendation was carried by a simple majority of one vote. Another expression of the opposition to the adopted scheme was heard at the annual meeting of the contributors to the infirmary held on Jan. 28th. The report there submitted contained the announcement that the managers had acquiesced in the scheme approved by the Jubilee Memorial Committee, with the proviso that the sole financial responsibility in connexion with the reconstruction shall rest with the last-named body. After the adoption of the report had been proposed Dr. Ebenezer Duncan moved an amendment disapproving of the action of the managers. He agreed that there was urgent need for a reconstruction of the infirmary, but argued that the proposal to erect on the present site a hospital to accommodate 700 patients was to perpetuate the present overcrowded condition of the infirmary and necessitated a building some parts of which would receive an inadequate supply of fresh air. The "plenum" system of ventilation would not, he considered, meet the wants of the infirmary, and he pointed out certain defects in it as revealed by the experience of the Victoria Infirmary. After a reference to the published opinion of the Institute of Architects he urged that the contributors should so far disapprove of the report and should appoint a small committee to meet the managers with a view to reconsider the whole question. The amendment was seconded, but on a vote was lost by 10 votes to 23 in favour of the report. As far as a show of hands is concerned, therefore, the managers and the Jubilee Committee are the victors, but it is impossible to deny that considerable dissatisfaction exists among the citizens and this must necessarily affect the subscription lists. The dispute is a most unfortunate one. The responsibility for it rests principally with those among the authorities who have systematically and somewhat superciliously disregarded that expert advice without which a satisfactory modern hospital cannot possibly be devised and erected.

The Sale of Poisons by Medical Practitioners.

The recent action of the General Medical Council in dealing with a medical practitioner who had been fined for permitting an unqualified assistant to sell poisons in his "open surgery," has caused considerable feeling in the West of Scotland where "open surgeries" are not infrequent. A meeting of practitioners to consider the question was held in Glasgow on Jan. 23rd, under the auspices of the Glasgow Southern and Eastern Medical Societies and the local branch of the British Medical Association. The chairman (Dr.

Watson) and several other practitioners severely criticised the action of the General Medical Council, and contended that the Pharmaceutical Society was entering on a crusade having for its object the entire suppression of the practice of selling drugs as at present conducted by some medical men. The right of retailing drugs was possessed by every individual, and it was only the sale of the scheduled poisons which was restricted to the chemist and druggist. A motion embodying these views was proposed by Dr. Charles Robertson. In speaking on the motion, Professor Glaister advised the meeting to proceed with caution. The facts of the recent case were not fully before the meeting and they certainly included the conviction on three separate occasions of unqualified assistants of the incriminated practitioner when summoned at the instance of the Pharmaceutical Society. He agreed that the desire of that society was to shut up the "doctors' shops," and he quoted in support of this view several clauses from the draft of a Bill which the society are promoting for submission to Parliament. Professor Glaister contended that the monopoly which the society aimed at would be intolerable, and he advised the meeting not to rest their case on the particular instance which had recently occurred but on the secure grounds of the rights which they possessed as citizens and medical practitioners. After several other speakers had addressed the meeting a motion was carried by a large majority representing to the General Medical Council that their recent decision is "unwarrantable and interferes with the rights and privileges of the profession as embodied in the Medical and Pharmacy Acts." A committee was also appointed to oppose the Pharmacy Acts Amendment Bill when this in due course is submitted to Parliament.

Small-pox in Glasgow.

The extension of the small-pox epidemic is assuming serious proportions. On Jan. 27th 11 new cases were admitted to hospital, making a total of 378 under treatment. The disease for the most part is not of a severe type, but there have been over a dozen deaths. An anxious feature of the epidemic is its widespread character. Cases have been detected in nearly every quarter of the city and the neighbouring burghs and townships are also beginning to suffer. It is feared that the disease will spread still more widely.

Jan. 29th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Chief Secretary for Ireland on the Registration of Plumbers.

ON Jan. 23rd a deputation of members of the Parliamentary Committee of the Irish Trades Congress waited upon the Right Honourable George Wyndham, Chief Secretary for Ireland, in Dublin, to urge his support of the aims of the Congress, including the registration of plumbers under statutory powers. In the course of a sympathetic reply Mr. Wyndham expressed his sense of the importance of plumbers' work and his opinion that a number of deaths and a great deal of disease were attributable to defective sanitation and to bad work by incompetent plumbers.

The Death of the Queen.

The winter meeting of the North of Ireland Branch of the British Medical Association was held in the Belfast Museum on Jan. 24th. The President (Professor J. W. Byers) on taking the chair said they met that day under circumstances of peculiar sadness. The heart of the British nation had been moved to its depths by the passing away of their august and peerless sovereign who from the age of 18 years to 81 years ruled with such perfect dignity and wisdom over an empire increasing in wealth and in extent as well as in scientific attainments. She was, as was truly said by Bismarck, "the greatest statesman in Europe" but she was beloved by her people and she won their affections because they admired her character and her matchless purity of life. In her exalted position her example in the Court and in her family had exerted a boundless influence throughout the entire world. The great Victorian era, which ended almost contemporaneously with the close of the century, had been a glorious one in the progress of science, and they who met there that day were no doubt above everything else thinking of the marvellous progress of medicine during the reign of their deeply-lamented Queen. The nation in all its departments had been affected by her life; it would be still more affected by her death if, quickened by the present universal sorrow, they all rose to a higher sense of duty and tried even at a distance to follow in the footsteps of her who during her entire life served her country so truly and so well. He begged to move the following resolution:—

That the members of the North of Ireland Branch of the British Medical Association meeting in Belfast desire most respectfully to record their profound sorrow at the calamity which has befallen the empire in the death of their beloved and revered sovereign, and to express their sincere and heartfelt sympathy with His Majesty the King and the other members of the Royal Family in their irreparable loss.

—Dr. P. Redfern having seconded the resolution it was passed in silence, all the members standing.—The President proposed that under the circumstances the ordinary business of the meeting be adjourned.—This was seconded by Professor W. Whitla and the meeting concluded.—Dr. W. Calwell (secretary of the branch) has forwarded to the King's secretary the resolution of condolence.

The Belfast Hospital for Sick Children.

At the annual meeting of this hospital, held on Jan. 26th, it was reported that during the year 573 children were intern patients, an increase of 99 over the previous 12 months. Of these 335 were medical, 223 were surgical, and 15 were eye and ear cases. There were 21 deaths, 14 in the medical ward and seven in the surgical ward. 292 operations were performed. There were 5235 extern patients. A large number of senior students are attending the hospital clinique. Owing to the generosity of certain friends of the charity the convalescent home has been open practically all the year. The receipts during the year amounted to £2463 0*s.* 1*d.* and the expenditure was £2021 13*s.* 8*d.*

Londonderry County Infirmary.

At the annual meeting of the Board of Management held in the institution on Jan. 24th it was reported that during 1900 1569 patients had been treated and of these 572 were intern; 103 operations were performed during the year. Financially there is a deficit of £216 17*s.* The subscriptions and donations are apparently £300 in excess of last year, but this is owing to special donations of £200 and £100. The reports were adopted.

The Forster Green Hospital, Belfast.

At the annual meeting of this hospital, held on Jan. 28th, it was reported that 119 patients had been treated in the hospital and 361 extern cases. The staff speak hopefully of the improved results of the open-air treatment of tuberculosis as compared with ordinary hospital treatment, but hold that patients must be sent in the earliest stages. Mr. F. Green has provided accommodation for 30 patients on an excellent site suitable for "sanatorium" treatment. It is hoped that the citizens of Belfast will all do their share in the matter. The past year's accounts show a deficiency of £214.

Jan. 29th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Hygiene in Theatres.

THE question of the hygienic arrangement of theatres is again to the fore and at the recent congress on Theatrical Art the Society of Medical Officers to Paris Theatres was represented by a committee of three. This committee handed in a number of important resolutions and asked that a medical man should be upon the Superior Committee of the theatres, as, singularly enough, up to now no medical man has been upon that committee. Certainly a member of the profession in question would be able to afford the committee valuable advice upon questions of ventilation and the like when plans for the reconstruction or building of a theatre come before it. A medical man could, for instance, in the case of the Comédie Française have ordered the disinfection of the dressing-room of one of the artistes who died from phthisis and whose successor who took over the room also contracted phthisis and died in her turn. M. Henriot, professor *agrégé* at the Faculty and a member of the Committee of Hygiene, has undertaken a scientific inquiry into the defects of the Paris theatres from a hygienic point of view and is taking samples for future analysis of the air from different parts of the house in the hope of discovering the microbes

of the diseases to which theatre-goers are liable. According to hygienic authorities theatres are insanitary for many reasons, chiefly because they are badly ventilated and badly lit in so far that they get no sunlight. The ventilating fan is no good, for it raises clouds of dust and is far worse in this matter than the feather broom. Then there is the floor upon which the audience frequently spits and which when swept gives off clouds of dust which rise in the air only to fall down again The most successful theatres, according to M. Henriot, are the most dangerous, for in them the audience stamps with enthusiasm and a quantity of dust is the result. M. Henriot's desiderata would be: 1. Better air and a natural system of ventilation. 2. Large windows through which the rays of the sun could enter. 3. All upholstery instead of being in velvet should be in leather and no stuff drop scenes should be allowed. 4. All wooden furniture should be varnished so that it could be washed over with a wet sponge. 5. The floor should be of some impermeable material so that it could be washed, and should be covered over with a layer of fine gravel which should be swept off every day, and would carry with it all dirt, dust, &c. (*scories*), without the dust floating up into the air. The medical officers of theatres ask for the installation in all theatres, cafés, concerts, and circuses of a "loge médicale," that is to say, a room kept specially for the purpose, to which can be removed any actor or spectator who may meet with an accident or be suddenly taken ill. The room should be of fair size to enable the patient to be easily attended to and must be ventilated by a window which opens easily. Its furniture should be only such as is necessary—viz., a sofa, a wash-basin, two or three hand-basins, some receptacle holding two or three litres of some antiseptic solution, and a cupboard for a few necessary drugs and dressings. There should also be a pair of scissors, a knife, a tongue forceps, a Pravaz syringe, and a night commode. The medical men who ask for this installation argue that in the great number of cases of accident cure depends upon immediate treatment by a medical practitioner, who must have the necessary articles for the application of such treatment.

Infant Mortality among the Urban Population of France.

At the meeting of the Academy of Medicine which was held on Jan. 8th M. Balestre and M. Giletta communicated a memorandum in the name of the Bureau of Hygiene at Nice relative to infantile mortality among the urban population of France. The memorial, which was drawn up in great detail, set forth that it was in the industrial and mining towns and in the large ports that infantile mortality was the heaviest. The departments with the highest death-rate were those where most alcohol was consumed, while the agricultural departments showed the lowest rate. More than three-quarters of the infantile deaths were due to avoidable causes, and in six years ignorance, want of proper care, alcohol, and other avoidable pathological conditions had given rise to 220,000 infantile deaths, which was equivalent to an annual loss of an army corps of 45,000 men. M. Balestre and M. Giletta thought that it was a matter for State intervention. The State should strengthen the existing laws relating to infant life protection, should draw up laws as to the protection of public health, and should enforce the existing regulations relating to unhealthy houses. Towns should have State assistance when undertaking sanitary improvements and the efforts to check the progress of alcohol should be furthered in every possible way. In conclusion M. Balestre and M. Giletta appealed to private charity to organise everywhere for the better protection of infants and to instal more generally those excellent *cliniques de nourissons* which at Paris, Fécamp, and elsewhere have given such excellent results.

Anæsthesia of the Spinal Cord during Labour.

M. Doléris, M. Malartie, and M. Dupaigne sent certain notes upon the employment of spinal anæsthesia to the Academy of Medicine, and at the meeting held on Jan. 22nd M. Guéniot read a paper founded upon the notes of these observers. He stated that if there was injected into the lumbar sub-arachnoid space 0·01 centigramme of cocaine in solution a localised anæsthesia was produced affecting the whole of the body below a line passing round the umbilicus. An injection of this kind given to a woman in labour did away with the pains caused by the contractions of the uterus and by the passage of the child. Furthermore, instead of delaying the course of labour it seemed to accelerate it. The anæsthesia lasted for about one and a half hours and the only toxic phenomena hitherto observed had been slight cramps or trembling of the limbs, a headache, which, however, soon passed off, a little sickness, and a small rise in temperature. These injections were contra-indicated in women with affections of the heart or of the great vessels, in any chronic disease of the respiratory organs or of the central nervous system, and, further, they should not be used unless perfect asepsis during the puerperium were obtainable. M. Guéniot drew attention to certain special contra-indications relating to the rate of labour, to the number and force of the uterine contractions, and, finally, to the necessity, or the contrary, for manual intervention within the uterine cavity. These three last contra-indications arise from the fact that cocaine is a powerful stimulant of uterine contractions. Indications for the use of cocaine in labour are as follows:—(1) any obstetrical operation necessitating the use of anæsthesia, except such as entail the introduction of the hand into the uterine cavity; (2) excessive pain, which sometimes occurs in labour; (3) delayed labour owing to feeble or irregular contractions; and (4) conditions likely to give rise to hæmorrhage, such as uterine inertia or vicious implantation of the placenta.

Jan. 27th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Financial Difficulties of a Hospital.

THE managing committee of the Kaiser and Kaiserin Friedrich Hospital for Children, an institution belonging to the class of "private hospitals," has informed the municipal authorities that it will be compelled by want of funds to close the wards on Feb. 1st. The municipal council has, therefore, decided to pay to the committee a sum of 30,000 marks (£1500) for the two months of February and March and a sum of 100,000 marks (£5000) for the financial year from April 1st, 1901, to the corresponding date in 1902. It was, moreover, resolved to enter into negotiations with the committee with a view to the hospital becoming a municipal one. This is, so far as I know, the first instance in which financial difficulties have rendered it impossible to carry on a hospital. The hospital system of Berlin is quite different from that of London, the hospitals being divided into three classes—State, municipal, and private. The Charité Hospital, the largest in Berlin, is a State hospital and contains the majority of the university clinics; apart from it several other university clinics have their own premises, for instance, the surgical and the obstetrical clinics. The second division includes the great municipal hospitals—the Friedrichshain Hospital, the Urban Hospital, and the Moabit Hospital; a fourth municipal hospital is in course of construction, the expenses being no less than 13,000,000 marks (£650,000). The third division includes the private hospitals which belong partly to religious communities, such as the Roman Catholic Hospital, the Jewish Hospital, the Bethanien Hospital, and others, and partly to private associations, such as the Augusta Hospital, the Lazarus Hospital, the Kaiser Friedrich Hospital, &c. The financial problems of hospitals are not so pressing in Germany as they are in England. It is the rule in Germany that hospital patients must pay for their accommodation a daily sum which in Berlin is fixed at 2 marks 50 pfennige (2*s.* 6*d.*). This condition is not so hard as it may appear. In serious cases patients are admitted without prepayment and as the whole working-class must belong to a sick club under municipal control the hospital charges are in the great majority of cases paid by the club. Those who do not belong to a club (almost exclusively very poor people without regular work, or women and children) either do not pay at all or are allowed to pay afterwards in small amounts. For the poor who are unable to pay anything the hospital charges are defrayed by the Armen-direction (guardians of the poor) if the patients have been admitted to the hospital by order of a poor-law medical officer (Armen Arzt) or if the case has been urgent. In many instances the hospital does not receive any money for individual patients, and this has been especially the case in the Kaiser Friedrich Hospital where the patients, being exclusively children, were, of course, not members of sick clubs, and their parents were mostly poor people. It is to be hoped that the municipal

council will agree to take over the hospital, so that its financial difficulties will be at an end. If the hospital were closed it would be a great misfortune both for the children of the poor and also for medical science, because much valuable work in connexion with children's diseases has been done there. It was in this hospital that anti-diphtheritic serum was first used on a large scale.

Ligature of the Coronary Artery.

Dr. Pagenstecher of Elberfeld, whose successful suturing of a wound of the heart was described in THE LANCET of Sept. 9th, 1899, page 747, has again had the opportunity of performing a similar operation and has published details of it in the *Deutsche Medicinische Wochenschrift*. The patient was an Italian workman who had stabbed himself in the chest with suicidal intention. When admitted into the Elberfeld municipal hospital he was found to be in a state of extreme shock and pulseless. He had lost an enormous quantity of blood, although there was at that time no hæmorrhage from the wound, which was situated in the fourth left intercostal space. The operation was performed two hours later. The fourth and fifth costal cartilages being divided, a flap was formed consisting of skin, muscle, and cartilage, and having its base towards the sternum. The mediastinum was found to be infiltrated with blood and air. It was difficult to ascertain the situation of the wound of the pericardium owing to the hæmorrhage but ultimately it was ascertained that it had been perforated on a level with the sixth rib. When the wound was enlarged air made its way into the pericardial cavity and the blood there was churned into a frothy state. The right ventricle proved to be enormously dilated, so that it seemed as if it might burst during the diastole, the heart muscle being degenerated. The right ventricle was turned aside with the finger and the left ventricle was brought into view. This had no prejudicial influence on the heart and it was found that the heart muscle itself was not injured, but that the left coronary artery was divided. The artery was tied and the pericardium and the skin were sutured without drainage. The operation lasted only half an hour. The patient was very excited immediately afterwards but became quieter on the following day. Subcutaneous emphysema appeared a few hours after the operation; the pulse was 120, strong and regular; the temperature was normal. On the third day the dressing was removed as the temperature had risen to 38·9° C. (102° F.) and there was dyspnœa. The emphysema had increased greatly, but the cardiac action was normal. On the fifth day the temperature rose to 39·2° C. (102 6° F.), the pulse was 130, and the dyspnœa was increasing; the wound was, therefore, opened again under chloroform and the sutures in the skin were removed. The pericardial cavity proved to be closed by adhesions. Puncture in the sixth intercostal space revealed the presence of sanguinolent fluid in the pleura, and on an incision being made several litres escaped. Half an hour after the second operation the patient died. At the necropsy purulent pericarditis and pleurisy with effusion were found. Degenerative myocarditis and chronic nephritis were also present. Apparently the pleura had been injured in the course of the operation. It was remarkable how little effect all that was done had upon the action of the heart.

Jan. 28th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Bellevue Hospital.

MATTERS at Bellevue Hospital appear to be reaching the acute stage. Three of the nurses accused of causing by violence the death of an inmate of the insane pavilion have been indicted by the grand jury and will have to stand their trial for homicide. Various other instances of inhumanity on the part of nurses have been reported as occurring both in the insane pavilion and in the alcoholic ward. As a result of the investigations promised by the Commissioner of Charities of New York City, who is in virtue of his post at the head of the municipal hospitals, many of the nurses have resigned, dreading probably the disclosures which may follow. The latest development, however, of the scandal is that the medical board are making common cause against the Commissioner, impelled to this course by the reflections cast upon them from outside and by the action of the Commissioner in discharging one of their number. Dr. Alan McLane Hamilton, a prominent alienist of New York, has written to the *New York Herald* formulating serious charges against members of the Bellevue Medical Board with regard to the treatment of the insane while in that hospital. As a matter of fact, everyone who is acquainted with the management of Bellevue Hospital is well aware that abuses exist and have existed for some considerable time in the working of the institution. It is the system which is in fault. The management of Bellevue Hospital is wholly controlled by politics, and to a person who is cognisant of the methods used by New York politicians this is a sufficient explanation of the trouble. The showing-up of the manner in which the New York city hospitals are governed will in the long run have a good effect. The entire system will inevitably be reorganised and city institutions will be placed on such a footing that they will really be of benefit to those persons for whose behoof they were established.

Epidemic of Influenza in the United States.

Influenza is at the present time epidemic throughout almost the whole of the United States. New York city has a very large number of cases, and although some of the lay journals, with their usual tendency to sensationalism and exaggeration, have magnified the gravity of the situation—stating that there are at present more than 400,000 sufferers from the malady—there can be no doubt but that it is very prevalent. The most encouraging feature with regard to the epidemic now in New York is the mild character that the disease has so far displayed. The deaths have been proportionately few. In January, 1899, there were 287 deaths for which influenza was held responsible. Most of the cases have been of the catarrhal type. Many prominent citizens are down with the troublesome complaint. In Chicago, where the number of cases is roughly estimated at 100 000, the epidemic is said to be raging in a more virulent form than for years. In Buffalo it is reported that a third of the population are prostrated with influenza. In Philadelphia much the same condition prevails and the physicians of that city state that the changeable weather which they are experiencing is daily developing fresh cases. Baltimore is another large American city in which influenza seems to have gained a foothold; reports thence say that not only has the disease spread widely but that it is of a severe type. Connecticut has 60,000 of its inhabitants suffering from influenza, in New Haven alone there being 10,000 cases. In many parts of the south influenza holds sway. In Washington the epidemic is on a widespread scale; many of the nation's legislators are incapacitated and the President himself has been confined to his bed for several days.

New Lying-in Hospital in New York.

There is approaching completion in New York city one of the most magnificent maternity hospitals in the world. This building, the cost of which with the site is said to have reached the sum of $1,000,000 (£200,000), has been given by the well-known financier, J. Pierrpoint Morgan. In addition to this Mr. Morgan has provided ample funds for its endowment. The building, which is of eight storeys, is a fireproof structure of steel, brick, and stone, about 150 feet in height. It faces Second Avenue, in which is its main entrance with a frontage of 184 feet; it extends along Seventeenth-street for 83 feet and along Eighteenth-street for 186 feet. The basement will be used for outdoor work. The first storey will contain the executive offices, the second the nurses' department, the third the septic department, and the fourth, fifth, and sixth storeys wards for patients, providing 200 beds; the seventh storey will be the operating-room, laboratory, kitchen, and laundry; and the eighth storey is occupied by an extension of the laboratory with amphitheatre seats for the operating-room. The heating of the building will be furnished by three boilers of 200 horse-power each. The motive power for the ventilating apparatus, elevators, laundry, kitchen, and for the ice-making and other plants necessary to a modern hospital will be provided by these boilers. There are two laundry plants, one of which is termed the septic laundry, in which a steriliser is to be placed, and the whole of the laundry machinery will be driven by electricity. The Society of the Lying-in Hospital of New York is one of the oldest charitable institutions for the benefit of the sick in the city. It was founded in 1798, and a small building in the poorest part of the town was utilised as a

shelter for homeless and destitute parturient women. It should be said that the new building is exceptionally handsome externally and is built of buff Indiana limestone and red brick.

Jan. 20th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Health of Sydney.

THE last quarterly report of the medical officer to the Sydney Water and Sewerage Board, which has just been issued, shows that the population of Sydney has increased by 11,350 since the corresponding quarter of 1899. The death-rate has also increased, especially from diarrhœa, typhoid fever, diphtheria, and phthisis, and Dr. T. M. Kendall states his opinion that so long as the present system of scavenging and removal of house refuse continues diarrhœa will flourish. The present system fills the houses in the city with contaminating dust, and the municipal garbage-tips are greatly responsible for the diphtheria mortality.

The Medical Practitioners Act of New South Wales.

The Bill to amend the Medical Act of New South Wales to]which I referred in a previous communication [1] passed its third reading in the Legislative Council, with the insertion of a fresh clause, moved by Dr. Nash, providing for the registration at the discretion of the board on a separate register of men who, though not properly qualified, could prove that they had passed a course of study at some recognised college or school and had conducted a reputable practice in New South Wales for 15 years prior to the passing of the Act. Such persons were to have all the rights of medical practitioners and be subject to all the provisions of the Act. The Bill was assented to and is now law and known as Act No. 33, 1900, and its administration has been placed under the control of the attorney-general. The New South Wales Branch of the British Medical Association accorded a vote of thanks to Mr. Price, M.L.A., who took charge of the Bill, for his work in successfully passing "the first Medical Bill worthy of the name in the colony." The branch recognised that to make the Bill acceptable it had necessarily to be short, but it was a great thing to have a satisfactory basis upon which additions might be built from time to time as expediency might suggest.

"Earth-eating Disease" in Queensland.

Dr. T. U. MacDonald, resident surgeon at the Geraldton Hospital, North Queensland, has stated that the disease known in North Queensland as the "earth-eating disease" [2] is assuming serious proportions in the northern towns. It has raged at Cooktown, Townsville, and Geraldton, and is extending nearly as far south as Brisbane. He had treated 120 cases, of whom 10 per cent. were adults. The earth-eating was merely a symptom, not necessarily constant, of a serious parasitic disease due to ankylostoma duodenale.

"The Battle of the Clubs."

At the inter-colonial conference of the boards of directors of the Australian Natives' Association the subject of the relations of the association with medical practitioners came up for discussion and, as might be expected at such a conference, the action of the New South Wales Branch of the British Medical Association which I referred to in a recent communication [3] came in for strong condemnation. The medical practitioners in New South Wales, however, are standing to their guns and will not accept positions as medical officers to the Australian Natives' Association. In Victoria the Medical Defence Association is organising the profession on the subject of women's lodges and other matters connected with the friendly societies. Under its auspices meetings have been held of all the medical men in all the various metropolitan and in several of the country districts, who have all agreed to certain definite and united action.

Sydney Hospital.

A conference has been held between representatives of the Sydney Hospital and representatives of the Hospital Saturday Fund Association with regard to the action of the latter body in withholding the amount allotted to the Sydney Hospital out of the year's collection pending an undertaking that the collectors of the hospital would refrain from attempting to collect when collections were being made by the association. After discussion the following proposals were drafted and submitted for the approval of both the hospital and the association and were adopted by the board of directors of the hospital :—

That the Sydney Hospital reserves the right to collect from any persons or body of persons on behalf of the hospital as an appeal to charity without offering any inducements other than those provided for in the bylaws.

That in the event of any such collection organised by the association being diverted to the hospital the association may fairly deduct the amount so diverted from the industrial portion of the fund when making the annual distribution.

Dr. C. E. Corlette has been appointed honorary assistant pathologist. The nurses at the Sydney Hospital have protested against the long hours which they have to work—80 per week—with only one full holiday of 24 hours in the year. The matter was brought under the notice of the Premier who has given instructions that the hours should be altered.

Prince Alfred Hospital, Sydney.

Dr. Gordon Craig has been appointed honorary assistant surgeon. Dr. N. W. Kater and Dr. G. Allen have been appointed clinical assistants in the out-patient medical department and Dr. T. S. Kirkland clinical assistant for the ear, throat, and nose department.

Melbourne Hospital.

The position of matron has become vacant by the resignation of Miss Farquharson and will probably be filled by a selection made in London. The salary is £200 per annum, with quarters. Dr. G. L. Laycock and Mr. H. L. Murray have been appointed honorary medical electricians.

Death of Staff-Surgeon J. Steel.

On Nov. 10th Staff-Surgeon J. Steel, of the New South Wales Naval Forces, died from an accident while on active service with the naval contingent at Taku in China, to the great regret of all who knew him. He was 45 years of age and was the son of the late Rev. Dr. Steel of St. Stephen's Church, Sydney. He received his medical education at Glasgow, Edinburgh, and Paris, and subsequently obtained the degree of M.B. at the University of Melbourne, having first passed the examination for the Licentiate of the Royal Colleges of Physicians and Surgeons of Edinburgh. He held the position of resident medical officer at the Royal Infirmary, Glasgow, and commenced practice in Sydney in 1882. Besides being a capable and successful practitioner Dr. Steel was a scholar and man of great literary attainments and a man of tender courtesy and generous heart. To his untiring energy and zeal the efficiency of the medical corps of the Naval Brigade was largely due. One of the special correspondents with the China contingent referred to Dr. Steel's heroic conduct during the forced march of the Australians to the Peitang forts as follows :—

It was a frightfully hot day, and sunstroke incapacitated a dozen. It was about 23 miles home, and of the 330 who formed the Australian contingent 40 returned from the halting-place on the railway line by train. The worst cases were taken to the hospital, where they speedily recovered, and the others marched out to the camp, and were warmly received by the party left in charge. The officer who came through the march with the most credit was the New South Wales surgeon, Dr. Steel. The Victorian surgeon was unable to stand the first marching, and remained in camp, Dr. Steel being left with the care of the officers and men of both bodies. Until the men began to fall his task was not more arduous than that of any other officer, but no sooner did one fall than the doctor was by his side administering stimulants, then doubling up to the main body again, arriving just in time to attend to another sufferer. The latter portion of the march was more like a series of running races for the doctor than a march. Nor had his work ceased when we camped for the night. Most of the stragglers made their way in, but there were still four victims missing at 10.30. Out went the doctor with a search party along the road, and for the greater part of the night he was busy with the sufferers. All the next morning he went on with his duties, but the sun got him at noon and he was carried unconscious to the railway station. After three days in the Gordon Hall Hospital he returned to camp to-day and got a splendid reception, the men cheering him again and again. He did double duty and did it well.

The Plague.

Lately two or three fresh cases of plague have occurred in Queensland, and on Nov. 17th a suspected case was reported by Dr. W. Irwin of Singleton, New South Wales, and Dr. Dick, the Government medical officer, was sent to report. He considered the case suspicious and isolation was enforced.

Dec. 26th, 1900.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the second professional examination for the Diploma of Fellow at the last half-yearly meeting of the examiners and the Diploma of Fellow has been issued to them by the Council of the College:—

Frederic Pinsent Maynard (Major I.M.S.), M.B. Durh., L.R.C.P. Lond., D.P.H., St. Bartholomew's Hospital, Diploma of Member dated April 28th, 1885; Edgar Godfrey Carpenter, L.R.C.P. Lond., D.P.H. Camb., St. Bartholomew's Hospital, Member August 1st, 1889; John Herbert Parsons, M.B., B.Sc. Lond., L.R.C.P. Lond., University College, Bristol and London, and St. Bartholomew's Hospital, Member Nov. 12th, 1891; Elmore Wright Brewerton, L.R.C.P. Lond., St. Bartholomew's Hospital, Member Feb. 7th, 1895; Alexander Gordon Wilson, M.B. Lond., L.R.C.P. Lond., London Hospital, Member May 13th, 1897; Edward Septimus Earnshaw Hewer, L.R.C.P. Lond., St. Bartholomew's Hospital, Member Feb. 10th, 1898; Irwin Walter William Hunter, M.A., B.Sc. New Zealand, L.R.C.P. Lond., Otago University, New Zealand, and London Hospital, Member May 4th, 1898; Percy William George Sargent, M.A., M.B., B.C. Camb., L.R.C.P. Lond., Cambridge University and St. Thomas's Hospital, Member May 4th, 1898; Thomas Alfred Mayo, M.B. Camb., L.R.C.P. Lond., St. Bartholomew's Hospital, Member Nov. 10th, 1898; William Archibald Logan, M.B., Ch.B. New Zealand, L.R.C.P. Lond., Dunedin University, New Zealand, and King's College Hospital, Member July 21st, 1899; James Sherren, L.R.C.P. Lond., London Hospital, Member July 27th, 1899; Robert James Johnstone, B.A., M.B., B.Ch. R.U.I., Royal University of Ireland and Queen's College, Belfast, not previously a Member. One other gentleman passed the examination, but not having yet attained the legal age of 25 years will receive his Diploma at a future meeting of the Council.

37 gentlemen presented themselves for this examination, 13 of whom assed and 24 were referred, 21 for six months and three for one year.

The following gentlemen passed the first professional examination for the Diploma of Fellow at the last half-yearly meeting of the examiners, viz.:—

Oliver Francis Haynes Atkey, King's College, London; Sidney Arthur Boyd, Charing Cross Hospital; Arthur Robinson Bailey, B.A. Camb., Cambridge University and Guy's Hospital; John Hay Burgess, St. Mary's Hospital; Harold Benjamin Day, King's College, London; Robert Valentine Dolbey and Arthur Sydney Downton, London Hospital; John Howell Evans, M.R.C.S. Eng., M.A., M.B., M.Ch. Oxon., L.R.C.P. Lond., Oxford University and St. George's Hospital; Robert John Ewart, M.R.C.S. Eng., M.B., Ch.B., B.Sc. Vict., L.R.C.P. Lond., University College, Liverpool; Francis Willoughby Goyder, B.A. Camb., Cambridge University and St. Mary's Hospital; Vivian Tudor Greenyer, M.R.C.S. Eng., L.R.C.P. Lond., St. Bartholomew's Hospital and King's College, London; Arthur Hyde Greg, M.R.C.S. Eng., L.R.C.P. Lond., Cambridge University and St. Thomas's Hospital; Arnold Gregory, Yorkshire College, Leeds; Walter Lidwell Harnett, University of Cambridge and St. Thomas's Hospital; Geoffrey Seccombe Hett, University College, London; David Morgan Hughes, University College, Cardiff; George John Jenkins, M.B., C.M. Edin., Edinburgh University and King's College, London; Francis Seymour Kidd, B.A. Camb., Cambridge University and London Hospital; Peter N. Lakshmanan, M.R.C.S. Eng., L.R.C.P. Lond., M.B., C.M. Madras, University of Madras and King's College, London; Stanley Thorpe Lewis, M.B., B.C. Camb., Cambridge University and Middlesex Hospital; Archie Trevor Moon, London Hospital; James Keogh Murphy, M.R.C.S. Eng., M.A., M.D. Camb., L.R.C.P. Lond., Cambridge University, St. Bartholomew's Hospital and King's College, London; Henry Bailey Mylvaganam, L.M. and S. Ceylon, Ceylon Medical College and London Hospital; Donald Luttrell Kilve Naesmyth, M.R.C.S. Eng., L.R.C.P. Lond., Charing Cross Hospital; William Robson Nichols, M.R.C.S. Eng., L.R.C.P. Lond., M.D., Trinity College, Toronto, Trinity Medical College, Canada, and University College, London; Frederick Norman, M.R.C.S. Eng., L.R.C.P. Lond., M.D. Brux., St. Bartholomew's Hospital and King's College, London; Francis Montagu Maxwell Ommanney, Guy's Hospital; Leslie Johnston Paton, B.A., B.C. Camb., Cambridge University and St. Mary's Hospital; Edwin Arthur Peters, M.R.C.S. Eng., M.D., B.C. Camb., L.R.C.P. Lond., Cambridge University, Guy's Hospital, and King's College, London; William Primrose, M.R.C.S. Eng., M.B., C.M. Glasg., Glasgow University, London Hospital, and King's College, London; William Arthur Rees, Middlesex Hospital; William Hunter Richards, M.B., B.S. Durh., L.S.A. Lond., Durham University, London Hospital, and King's College, London; William Jones Richards, M.R.C.S. Eng., L.R.C.P. Lond., St. Bartholomew's Hospital; Harold Rischbieth, B.A. Camb., Cambridge University and London Hospital; Reginald Henry Robbins, B.A. Camb., Cambridge University and St. Mary's Hospital; Ernest Edward Robert Sawrey, M.D., B.S. Melb., University of Melbourne and King's College, London; Arthur Rendle Short, B.Sc. Lond., University College, Bristol; Thomas De Smith, B.A. Camb., F.C.S., Cambridge University and London Hospital; Ernest Malcolm Stockdale, M.R.C.S. Eng., L.R.C.P. Lond., University College, Liverpool; Hubert Maitland Turnbull, B.A. Oxon., Oxford University; and Edward Allan Wilson, Yorkshire College, Leeds.

89 gentlemen presented themselves for this examination, 41 of whom were approved and 48 were referred.

DR. MARTIN HAHN has been commissioned by the Bavarian Government to proceed to Egypt and India for the purpose of studying the plague.

MEDICAL MAGISTRATES.—Mr. Alfred Roberts Steele Perkins, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A., and Mr. John Delpratt Harris, M.R.C.S. Eng., L.S.A., have been placed on the Commission of the Peace for the city of Exeter.

VACCINATION GRANT.—Mr. G. Shepley Page, L.R.C.P., L.R.C.S. Edin., the public vaccinator for the Bristol district of the Bristol Union, has been awarded a grant for successful vaccination by the Local Government Board.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. E. Ingals, formerly Professor of Forensic Medicine in the Rush Medical College, Chicago.—Dr. Depasse, Director of the Imperial College of Medicine, Tientsin.—Dr. Robert Moericke of Stuttgart, formerly Professor of Midwifery in Santiago, Chile.—Dr. Julius Lehmann of Copenhagen, one of the chief hygienists of Denmark.—Dr. Chatin, honorary director of the École Supérieure of Pharmacy in Paris.—Dr. Wilhelm Wellner of Fürth, who has written on the subject of mercurial poisoning amongst workers in the mirror factories for which Fürth is famed.—Dr. Alexander Spengler of Davos, who was one of the first to bring Davos into prominence as a resort for phthisical patients. Two of his sons are practising there. He was 73 years of age.

LITERARY INTELLIGENCE.—Mr. Mortimer Menpes's book, "War Impressions," is in the press and will be ready in about a month. Its chief feature will be 97 page illustrations in colour, of which a large number are portraits sketched by permission in the field. These include Earl Roberts, Sir Alfred Milner, Cecil Rhodes, General French, General Macdonald, and General Pole-Carew, and practically everyone whom the campaign has brought into prominence. Other subjects of illustration are Boer prisoners on their way to Paardeberg, Modder River, City Imperial Volunteers in camp, and Lord Roberts watching the battle of Osfontein. The volume also contains a series of autograph letters, in facsimile, from Earl Roberts and several of the generals, as well as reproductions of a Boer doctor's letter and a Boer plan of the battle of Magersfontein. Besides the ordinary edition there will be an edition de luxe on hand-made paper, limited to 350 copies. Messrs. A. and C. Black are the publishers.

RURAL DISTRICTS OF BUNTINGFORD, &C., AND CERTAIN URBAN DISTRICTS.—Medical Officer of Health. Salary £600 per annum, including travelling and all other expenses.

SALFORD ROYAL HOSPITAL.—House Surgeon, salary £100 per annum; also House Physician, salary £80 per annum; also Junior House Surgeon, salary £70 per annum, with board and residence in each case.

SALOP INFIRMARY.—Assistant House Surgeon for six months, capable of renewal for a further period of six months. Salary at the rate of £60 per annum, with board and washing.

ST. BARTHOLOMEW'S HOSPITAL, Rochester.—House Surgeon, Salary £120 per annum, with board, lodging, washing, firing, and light.

STOCKPORT INFIRMARY.—Junior Assistant House Surgeon for six months. Salary at the rate of £24 per annum, with board, washing, and residence.

THE CHIEF INSPECTOR OF FACTORIES gives notice of vacancies as Certifying Surgeons under the Factory Acts at Somerton, in the County of Somerset; and at Limerick, in the County of Limerick.

WARNEFORD ASYLUM, Oxford.—Assistant Medical Officer, unmarried. Salary £100 a year, with board, lodging, and washing.

WEST BROMWICH DISTRICT HOSPITAL. — Resident Junior House Surgeon. Salary £50 per annum, with board, lodgings, washing, and attendance.

YORK COUNTY HOSPITAL.—Resident Assistant House Surgeon. Salary £60 per annum, with board, attendance and washing.

Births, Marriages, and Deaths.

BIRTHS.

MACK.—On Jan. 26th, at Roman-road, North Bow, E., the wife of H. Hamilton Mack, B.A. Adelaide, L.R.C.P. Lond., of a daughter.

MANSELL.—On Jan. 28th, at Crofton, West-hill, Hastings, the wife of Harry R. Mansell, M.R.C.S., of a son.

ROBINSON.—On Jan. 16th, at Rocester, Stafford, the wife of Bernard Robinson, L.R.C.P., M.R.C.S., of a son.

DEATHS.

EKENS.—On Jan. 28th, Joseph William Ekens, M.R.C.S., aged 54 years.

KNOWLES.—On Jan. 25th, at 5, Ashford-road, Maidstone, John Knowles, M.R.C.S., aged 52 years. Interred at Maidstone Cemetery on Jan. 29th.

VERNON.—On Jan. 28th, at Clarges-street, Piccadilly, Bowater John Vernon, F.R.C.S., Ophthalmic Surgeon to St. Bartholomew's Hospital.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

RETRIBUTION FOR A QUACK.

ON Jan. 25th a case was heard before His Honour Judge Parry in the Manchester County Court in which a Mrs. Fell brought an action against W. Mellor of Offord-road, Manchester, to recover a sum of 10 guineas. Counsel for the plaintiff said that she had a daughter whose sight was affected. At the end of 1898 Mrs. Fell saw a pamphlet in which the defendant advertised himself as "the only eye specialist in Manchester," and undertook to cure diseases of the eye without operations. The pamphlet contained testimonials and a notice to the effect that the defendant guaranteed to effect a cure in every case. Plaintiff took her daughter to the defendant who said that he would refund the 10 guineas if a cure was not made. Plaintiff's daughter said that defendant had told her that there were ulcers affecting her eyes. Dr. Hill Griffith, however, said that he had examined the girl's eyes and gave it as his opinion that they had not been affected by ulcers, at all events for a long time. Defendant said that he had practised with great success for 20 years. He had obtained his training in Australia under his father-in-law, who was not a doctor but a Trinity College man. He had stopped the issue of the pamphlet in question because he thought it was "too big." His Honour, in giving judgment, said that a man could not be criminally prosecuted for practising as the defendant was doing, but it was a question for the community whether it would not be better to make such men's position legal. A man who could send out thousands of papers with such absurd guarantees by way of alluring people to his place would promise anything for the sake of 10 guineas. Judgment would be for the plaintiff and he hoped that the public would take warning from the case not to enter into such foolish contracts with men of the class of the defendant. His Honour will be, we fear, disappointed. There will always be silly persons who will consult quacks or buy Bodger's Blue Boluses. We are glad to see, however, that his Honour suggested the advisability of making such men's position legal, by which we suppose he meant putting them into a position where the law could take cognisance of their deeds. We cannot see why quacks should not be made to hold a licence to practise. A man has to have a licence to sell tobacco or buttons in the street, and such licence in no way implies any guarantee of the goods. The licence should cost a great deal, say £200; it should be necessarily renewable annually and should be able to be withdrawn without any reason being given. The same law should apply to all sellers of quack medicines; that is to say, the trade should be so heavily taxed that it would not be worth the quack's while to continue it.

FRERE'S ARSENICAL PASTE.

To the Editors of THE LANCET.

SIRS,—I should be much obliged if any of your readers would give me information regarding the efficacy of Frere's arsenical paste (Squire's formula)—arsenic, 1; charcoal, 1; red sulphide of mercury, 4; and water, q.s.—as a means of destroying a small rodent ulcer of about the size of a split pea situated half an inch from the eye, and also information in reference to any points in its use—i.e., indications for length of time the application should be made and best after-treatment with a view to preventing a scar that will contract and draw the lower eyelid down. In the case in question any efficient method of getting rid of the ulcer is preferable to the use of the knife.

I am, Sirs, yours faithfully,

Jan. 22nd, 1901. L.R.C.P. LOND., M.R.C.S. ENG.

A NEW FRAUD: A WARNING TO THE WIVES OF MEDICAL MEN.

To the Editors of THE LANCET.

SIRS,—May I through your columns warn the wives of your medical readers against a species of fraud of which they may become the victims? I can best describe the plan by relating my experience. Last week a respectably dressed woman called at my house representing herself as a hospital patient of my husband upon whom he had operated, and saying that he had asked her to come and report progress to him and to leave a message with me should he be out. As she gave the name of a hospital to which he is attached her tale sounded most plausible. She said she was much better and strong enough to work and was going back to the firm at which she had been employed before her operation. But wages were only paid at the end of the week and her illness had swallowed up all her money. Could we lend her a shilling or two to be going on with? I regret to say I was thrown off my guard by her story and let her have a small sum of money. Of course my husband knew nothing of her when I questioned him, and I feel sure she is going the round of medical men's houses with some such tale, first looking up the hospital appointments of the intended victims.

I am, Sirs, yours faithfully,

Jan. 28th, 1901. M. H. G.

"CHRONIC DIARRHŒA: SUGGESTIONS FOR TREATMENT DESIRED."

To the Editors of THE LANCET.

SIRS,—In answer to "Perplexed," in THE LANCET of Jan. 26th, p. 296, I have found benefit in similar cases to the one he describes from: 1. Restriction of fluid, allowing no liquid till the solid meal has been eaten and then drinking moderately. 2. From an infusion of oak bark. Pour a quarter of a pint of boiling water upon two drachms of oak bark; let it stand for two hours and strain or filter; drink a wineglassful three or four times a day. It should be made fresh daily. The decoction of oak bark is too strong and does not act as well. 3. If opium in any form is needed I have never found any preparation of so much service as the compound kino powder—10 grains in an ounce of water arrowroot two or three times a day, and when it seems to have answered its purpose diminishing the frequency of the dose. 4. A warm pad round the abdomen is useful.

I am, Sirs, yours faithfully,

Jan. 28th, 1901. K.

OBSTETRIC PRACTICE IN NEW ZEALAND.

To the Editors of THE LANCET.

SIRS,—Will any reader of THE LANCET well acquainted with New Zealand kindly give information as to the prospects of practice, private or otherwise, that would be open to a legally qualified British lady practitioner who makes obstetrics her specialty settling there?

I am, Sirs, yours faithfully,

Jan. 3rd, 1901. ÆSCULAPIA.

THE VOCABULARY OF NEUROLOGY.

To the Editors of THE LANCET.

SIRS,—As a student of medicine who has this evening been immersed in the study of the spinal cord, will you allow me to suggest that the various authorities on that region of the body should come to some definite conclusion regarding its terminology? At present no two books seem to agree in the least on this rather important matter, except that most of the names attached to the various tracts vie with each in leaving the reader in the dark as to their probable function. For instance, there is a tract, whose anatomical position is antero-lateral, which, as far as I can see, may be called the comma tract, the ascending antero-lateral tract, the ascending cerebellar tract, or the tract of Gowers. One of my tomes also kindly warns me against confusing it with the descending tract of Schultze which is also sometimes known as the comma tract. Surely such a multiplication of verbiage is undesirable. Probably to you, Sirs, these various names have so long been known to be synonymous that you may fail to see my difficulty. And I admit that, now that I have collected them together and copied them out, I shall probably never have any further trouble with them. But consider that I have spent a whole evening over the performance, and that, on countless other evenings, I have recoiled with a reeling brain when only half way through it; and you will recognise that my plea, which is made on behalf of generations of medical students yet unborn, or not yet through their first professional, is a worthy one. And if, through you, I can reach the ear of Ferrier or Gowers I shall go to bed feeling that, though I have done practically no work to-night, I have accomplished something to ameliorate the sufferings of the medical student.

I am, Sirs, yours faithfully,

E. M. GLANVILLE.

Edinburgh University, 1 A.M., Jan. 29th, 1901.

"THE CERTIFYING OF STILLBORN INFANTS."

A CORRESPONDENT points out that in our annotation published on Jan. 19th (p. 195) under this heading the technical aspect of the cause is not accurately represented. The defence relied upon was not that a medical man is justified in giving a stillborn certificate for a child practically dead but that the child was not viable, never had lived, and the certificate was a proper one to be given under such circumstances.

A NEW REACTION FOR SUGAR.

IN the *Deutsche Medicinische Wochenschrift* of Jan. 17th Professor E. Riegel describes a new method of applying the phenylhydrazin test for sugar. As much pure white hydrochloride of phenylhydrazin as will lie on the point of a small knife (0·1 gramme) is put into a somewhat large test-tube; to this are then added 0·5 gramme of crystallised sodium acetate, one cubic centimetre (20 drops) of the sugar solution, and two cubic centimetres of water; the test-tube is now heated to boiling over a spirit lamp and 10 cubic centimetres of a 10 per cent. solution of soda are immediately run in; the test-tube is then shaken five or six times and left at rest. Either immediately or after the lapse of some minutes the whole solution assumes a fine red-violet colour. Exactly the same method is followed in testing for sugar in the urine. Into a large test-tube are put 20 drops (one cubic centimetre) of urine, 0·1 gramme of pure white hydrochloride of phenylhydrazin, 0·5 gramme of crystallised sodium acetate, and about two cubic centimetres of water. The whole is then heated to boiling over a spirit lamp. 10 cubic centimetres of a 10 per cent. solution of soda are immediately run in, the test-tube is shaken five or six times and left to rest. If the amount of sugar present exceeds 0·1 per cent. the fluid will in a few seconds assume a red-violet colour. In testing for sugar in the urine it is essential that the colour should be viewed by transmitted light, that the fluid should be coloured throughout, not merely the precipitated phosphates, and that not more than five minutes at the most should be allowed for the red-violet colour to make its appearance, for after a longer period even normal urines and such as do not contain a pathological amount of sugar become coloured. The delicacy of the reaction may be considerably increased by proceeding in the following way. The above quantity (0·1 gramme) of pure white hydrochloride of phenylhydrazin is put into a shallow porcelain basin about three centimetres in diameter; to this are added 0·5 gramme of crystallised sodium acetate and 20 drops (one cubic centimetre) of the sugar solution; the basin is then held in crucible tongs over a spirit lamp until everything is dissolved and the fluid boils; it is then laid on the table and from 20 to 30 drops of a 10 per cent. solution of soda are added—best out of a dropping glass—without shaking the basin. Either in a few seconds or after about five minutes the fluid becomes red-violet, even when the solution of sugar contains no more than 0·005 per cent. of it. If the solution examined contains no sugar a slight pink tint makes its appearance in from 15 to 30 minutes as the result of atmospheric oxidation. Sugar in urine may be tested for in exactly the same way, but not more than one minute must be allowed for the development of the red-violet colour. Aldehydes give the same reaction as sugar and must therefore not be present.

THE DENTON EXPLOSION.

MUCH cannot as yet be said as to the exact cause of the disastrous explosion which took place at some hat works at Denton on Jan. 14th. This much, however, seems to be made out: (1) that the "proof" house where it took place was filled with the vapour of methylated spirit; and (2) that a new patent drying-stove on which some suspicion had been cast was not in use at the time. The report of the explosion was heard for many miles, having been noticed by residents in Broughton and Moss Side, two widely separated parts of Manchester. Up to Jan. 19th 14 deaths had taken place, five of them at the Manchester Infirmary.

REMOVED FROM THE ROLL.

To the Editors of THE LANCET.

SIRS,—I am directed by the President and Fellows of the Royal College of Physicians of Ireland to forward you the inclosed copy of a letter which has been sent to the coroner for the city of Westminster.

I am, Sirs, yours faithfully,

Jan. 22nd, 1901. JAMES CRAIG, M.D., Fellow and Registrar.

[COPY.]

Royal College of Physicians, Ireland,
Kildare-street, Dublin, Jan. 19th, 1901.

JOHN TROUTBECK, Esq., Coroner for the City of Westminster.

SIR,—In connexion with the inquiry recently held before you concerning the death of Chrystabel Ham who died at King's College Hospital on Dec. 22nd, 1900, at which inquiry Charles Lumley is reported by the *Daily Telegraph* to have stated that he is an L.R.C.P. (Dublin), I am directed by the President and Fellows of this College to inform you that Charles Louis Lumley was deprived of his Licences and his name erased from the Roll of Licentiates of the College on July 24th, 1900.

Yours faithfully,

(Signed) JAMES CRAIG, M.D.,
Fellow and Registrar.

PARACUSIS OF WILLIS.

WITH reference to this anomaly of hearing, by which auditory acuity is greater in a railway train or in other places where the environment is full of confused sounds, a correspondent writes to us: "I saw lately an old woman with old chronic dry catarrh of middle ears. Her husband brought her, and when I was asking questions leading up to the existence of 'paracusis' he related how some years ago in a train as he was relating to others present some not over-refined pleasantry about his wife, trusting to her deafness, she suddenly caught him a cuff on the head because, to his astonishment, she heard perfectly well."

"MAGAFFIN."

WE have given this excellent paste considerable practical trial with very satisfactory results. It consists of a modified starch manufactured in a special manner which renders it glairy and at the same time tenacious. It is very clean to use, containing no "gluey" substances which in a great number of pastes give to them a very disagreeable smell. The paste is quite permanent and contains an agreeable antiseptic. It may be had in concentrated form, which is a great advantage where large quantities are in constant use, as in newspaper offices and other places where labeling is required. The paste is prepared by the Magaffin Co., of 49, Eagle-street, Holborn, London, W.C.

THE FIGHT AGAINST TUBERCULOSIS.

THE Committee of the National Sanatorium for Consumption and Diseases of the Chest at Bournemouth recently asked their resident medical officer, Dr. A. E. Burroughs, to draw up a little set of rules for consumptives. This he has accordingly done and has also forwarded a copy to us. A copy is sent to every applicant for admission and the rules are practically an abstract of the treatment pursued in the institution. They are perfectly plain and simple

and we have nothing but praise for them, except that we think that the statement about the cold bath is rather too sweeping. However, perhaps even this may be read permissively. Short rules are given as to the dangers of the sputum and the way in which these are to be avoided. Personal and local cleanliness is insisted upon and there is a timely warning to patients not to neglect these rules of hygiene after they return home.

COTTAGE BATHS.

THERE is some hope that the Manchester Corporation will at length give a favourable response to the oft-repeated prayers for cottage baths in Hulme. The question was considered at a meeting of the Baths Committee on Jan. 16th. Alderman Evans brought forward a resolution from the Ladies' Health Association "praying the committee to provide cottage baths for the poor people in the Hulme district." A sub-committee was appointed to consider the question and report on the best method of trying the experiment. The idea is to fit up a large cottage with baths where the mothers may take their children and "wash them more frequently and readily than can be done now in many of the houses of the poor." All who are regardful of the wants of the poor will wish the scheme every success.

PROGNOSIS AND CLASSIFICATION OF HYSTERIA.

DR. JOSEPH FRAENKEL of the New York Hospital for Nervous Diseases has published in the *New York Medical News* of Jan. 5th a concise and interesting article on the prognosis and classification of hysteria in which he deals with the interesting question as to how far the disease may be regarded as fatal, a point which the text-books seem to neglect. Hysterical disorders are divided into three main clinical groups which, he observes, are not sharply demarcated, as many intermediate and complicated types may be met with. The first group comprises the predominantly mental forms—i.e., hysterical psychosis with more or less pronounced somatic symptoms. The second group includes those with disturbances affecting a lower level of the nervous system—e.g., the cerebro-spinal forms. The symptoms of this group mainly consist of phenomena of paralysis of motor and sensory nerves and phenomena of irradiation. The third group is marked by disturbances which are predominantly splanchnic in their distribution—i.e., visceral and vascular disturbances, and including those of digestion and secretion such as vomiting, constipation, diarrhœa, meteorism, ulcerations, œdemata, &c. Around these main groups there cluster the varying kinds of hysterical seizures and crises, *grand ou petit mal hystérique*. As regards prognosis he believes that this is favourable in the first and second groups of cases. In the third or splanchnic group, however, a few cases have been recorded which have ended fatally, and amongst these Dr. Fraenkel enumerates four cases which had been under personal observation, three of which had ended fatally while under observation during the course of two years. Dr. Fraenkel points out that in fatal cases death is believed to be due to paralysis or spasm of the glottis, or is the result of inanition following persistent hysterical anorexia, or is due to uncontrollable hysterical vomiting. These modes of death do not include the rare cases which end by suicide. The three cases of Dr. Fraenkel are of rare and exceptional interest, and the first of these is as follows. A woman, aged 42 years, single, suffered from severe hysteria with anorexia for nine months. There was no attributable cause for the onset of her symptoms, and her family history was good. On admission to hospital the chief symptoms were emaciation, anorexia, vomiting, and obstinate constipation. The pulse and temperature were subnormal. No organic disease could be found by repeated examination. "The patient took only a small amount of nourishment, and after two weeks she died suddenly, apparently of exhaustion." The necropsy revealed the following conditions. There were small hæmorrhagic erosions in the stomach and scattered spots of ulceration in the small and large intestines. These ulcerations were dark and parchment-like, and very similar in appearance to trophic ulcerations of the skin. The brain and spinal cord showed no changes to the naked eye, excepting that the meninges were unusually dry. The patient was embalmed prior to the performance of the necropsy, so that the results of microscopical examination (in the form of slight changes in the central nervous system) were not regarded as trustworthy or genuine, inasmuch as the possibility of their being artifacts had to be borne in mind. The sympathetic nervous system was not examined. Dr. Fraenkel therefore concludes, and his conclusion is supported by Fournier, that it is reasonable to assume that in hysteria death when it occurs is due to "irritation or paralysis of splanchnic or vegetative functions and that a case of hysteria with more or less constant and prevailing splanchnic or vegetative symptoms is from a prognostic standpoint to be adjudged very cautiously."

Astrion.—1. The question as asked by our correspondent is too vaguely put. The giving of the appointment would probably vary according to the port of exit and of entry. Our correspondent had better write to the Colonial Office, the Board of Trade, and the Emigrants' Information Office, the address of which last establishment is 31, Broadway, London, S.W. 2. We do not know the formula of the particular preparation in question. The formula for "grey oil," as given by Dr. E. Lang of Vienna, who introduced it into practice, is as follows: Lanolini anhydrici, four drachms; chloroformi, half an ounce. Evaporate in a large mortar with continual stirring down to one ounce. Then add one ounce hydrargyri vivi depur., stir slowly until the chloroform is wholly evaporated and the metallic mercury can be no longer distinguished. This preparation is known as unguentum cinereum laninolatum forte. To prepare an injection of 50 per cent. strength, which is the one most commonly used, take of the above ointment 135 grains and ol. vaselini 45 grains; add the oil to the ointment very gradually with constant stirring until a smooth oily mixture is obtained. The dose given is usually 0·05 cubic centimetre.

Enquirer (2) must, we think, look to his own patient for the fee. He attends the consultation in the plaintiff's interest, for it would harm his case if he declined to go.

W.H.—The objection urged is a possible one.

ERRATUM.—In the report of Dr. Churton's paper on Disease of the Prefrontal Lobes, published in THE LANCET of Jan. 26th, the name "Lichen" at page 251, col. 1, line 9, ought to be *Ziehen*. The passage at lines 29–32 of the same column ought to be as follows: "..... malingering were included in the first division. As illustrations of disorders characterised by depression of the activity of the prefrontal cells cases were briefly related....."

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (4th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M.).

TUESDAY (5th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

WEDNESDAY (6th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.)

THURSDAY (7th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.) University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

FRIDAY (8th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

SATURDAY (9th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (4th).—OTOLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos-street, Cavendish-square, W.).—4.30 P.M. Cases will be shown by Dr. D. Grant, Dr J. Horne, Dr. Milligan, Mr. de Santi, Dr. StClair Thomson, and Mr. P. M. Yearsley. Specimens will be shown and Notes of Cases read by Mr. C. A. Ballance, Dr. A. Bronner, Mr. A. Cheatle, Sir W. Dalby, Mr. C. H. Fagge, Dr. D. Grant, Mr. R. Lake, Dr. Milligan, Dr. U. Pritchard, and Dr. StClair Thomson. A Discussion will follow each item.

TUESDAY (5th).—PATHOLOGICAL SOCIETY OF LONDON (Medical School of St. Bartholomew's Hospital).—8 P.M. Laboratory Meeting. Dr. Andrewes and Dr. Schölberg: The Relative Agglutination Phenomena seen after Immunisation against the Typhoid Bacillus and its near allies.—Dr. Garrod and Dr. Drysdale: The Action of Intestinal Bacteria upon Bilirubin.—Dr. Klein: (1) A New Pathogenic Torula; (2) Agglutination of Plague Bacilli.—Dr. M. Gordon: Bacillary Forms of Streptococci.—Dr. Andrewes and Dr. Horne: Demonstration of the Collodion Method applied to Paraffin Sections for Class Purposes.

WEDNESDAY (6th).—OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Mr. H. Gliford (introduced by Mr. Targett), Dr. W. Duncan, and others. Annual Meeting. Mr. A. Doran (President): Annual Address.

THE ELIZABETHAN SOCIETY (Toynbee Hall, 28, Commercial-street, E.).—8 P.M. Mr. D'Arcy Power: The Elizabethan Revival of Surgery in England.

THURSDAY (7th).—HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne-street, Edgware-road. W.).—8.30 P.M. Dr. I. Parsons: Persistent Menorrhagia and its Treatment.

FRIDAY (8th).—ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND (College, Guy's Hospital, S.E.).—4.30 P.M. Exhibition of Specimens by Mr. W. L. Duckworth, Mr. A. M. Paterson, Mr. H. L. Barnard, Prof. Dixon, and Mr. A. Keith. Papers:—Mr. W. H. Gaskell: The Origin of the Vertebrate Ear and Eighth Pair of Cranial Nerves.—Mr. W. L. H. Duckworth: A Critical Review of Recent Literature on Fossil Anthropoids.

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich-road, S.E.).—8 P.M. Special General Meeting. 8.45 P.M. Ordinary Meeting. (Postponed from Feb. 1st, owing to the funeral of the Queen.)

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith-road, W.).—Ordinary Meeting.

CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Papers:—Dr. Nabarro (introduced by Dr. Thin): A Case of Pronounced Splenomyelogenic Leucocythæmia subsequent to an attack of Malarial Fever.—Mr. E. W. Shenton (introduced by Dr. J. H. Bryant): Instantaneous Radiography.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (4th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. A. Whitfield: Consultation. (Skin.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. McAdam Eccles: Lantern Demonstration of Hernia Cases.

TUESDAY (5th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. C. T. Williams: Consultation. (Medical.)

WEDNESDAY (6th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—5 P.M. Mr. S. Boyd: Clinical Lecture.

LONDON THROAT HOSPITAL (204, Gt. Portland street, W.).—5 P.M. Dr. Cathcart: Examination of the Larynx. (Post-graduate Course.)

THURSDAY (7th).—CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL (Gray's Inn-road, W.C.).—5 P.M. Dr. D. Grant: Treatment of Tuberculous and other Specific Affections of the Pharynx and Larynx.

CHARING-CROSS HOSPITAL.—4 P.M. Mr. Waterhouse: Surgical Cases. (Post-graduate Course.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—3 P.M. Dr. H. Low: Class. Roentgen Rays. 4 P.M. Mr. J. Hutchinson: Consultation. (Surgical.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. McAdam Eccles: Lantern Demonstration of Hernia Cases.

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. Poynton: Demonstration of Selected Cases.

THE HOSPITAL FOR DISEASES OF THE SKIN (Stamford-street, Blackfriars).—3 P.M. Clinical Demonstration:—Dr. P. S. Abraham.

FRIDAY (8th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. T. Collins: Consultation. (Eye.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—In consequence of the death of Her Majesty the Queen the Hunterian Dinner, which had been announced for Feb. 14th, will not take place. The Hunterian Oration will, however, be delivered by Mr. N. C. Macnamara, as already announced, at 4 P.M. on Feb. 14th. The College will be closed on Saturday, Feb. 2nd.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1900, which was completed with the issue of Dec. 29th, and the Title-page to the Volume were given in THE LANCET of Jan. 5th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1900, bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half-year's numbers, cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Office, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been received from—

A.—Dr. B. Addenbrooke, Kidderminster; Anglo-Continental Guano Works Lond.; Messrs. Allen and Hanburys, Lond.; Alpha, Lond.: *Archives Générales de Médecine*, Paris, Editor of.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France,—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

An Address
ON
GASTRIC HÆMORRHAGE AND ITS SURGICAL TREATMENT.

Delivered before the Edinburgh Medico-Chirurgical Society on Wednesday, Feb. 6th, 1901.

BY A. W. MAYO ROBSON, F.R.C.S. ENG.,

SENIOR SURGEON TO THE GENERAL INFIRMARY AT LEEDS; EMERITUS PROFESSOR OF SURGERY IN THE YORKSHIRE COLLEGE OF THE VICTORIA UNIVERSITY.

MR. PRESIDENT,—I can assure you that I feel it a very high honour to be asked to give an address before so distinguished a society as the Edinburgh Medico-Chirurgical Society, and as the northern capital has for ages been such a stronghold of medicine I should almost have hesitated in venturing on another trespass of surgery had I not felt that the opinion held by many practitioners of medicine "that bleeding from the stomach, the result of ulceration, rarely proves fatal," required carefully reconsidering and the facts marshalling and looking at also from the surgical point of view.

Just as in other internal hæmorrhages, bleeding from the stomach was until quite recently a subject that so far as treatment is concerned only came under the notice of the physician, and it is only since the advances in surgery have demonstrated the feasibility and safety of exploring the abdomen that the question of the surgical treatment of hæmatemesis has been a subject that could be discussed with advantage in a mixed medical and surgical society. Were it desirable, the time at my disposal this evening would render it impossible to consider all the varieties of hæmatemesis. I shall therefore confine my remarks altogether to the most common and certainly the most important cause of gastrorrhagia, simple ulcer, leaving out of consideration the vomiting of blood from cirrhosis of the liver, cancer of the stomach, miliary aneurysm, aneurysm of the aorta and other vessels, purpura, scurvy, heart disease, leukæmia, typhoid fever, and other more obscure conditions only amenable to medical treatment.

When it is borne in mind that gastric ulcer occurs in 5 per cent. of the community and that according to Brinton, Habershon, Müller, Dreschfeld, Lebert, and others the mortality from all causes in all cases of ulcer is from 10 per cent. to 50 per cent. it must be at once allowed that the consideration of the subject is a matter that should claim the attention of the profession to a greater extent than it has hitherto done. Its importance will be better grasped if these figures are applied to the population of a city like Leeds which, for convenience' sake, I will take at 500 000. Of this number 25,000 persons may be supposed to have or to have had ulcer of the stomach and out of these, taking the mean estimate of mortality as 25 per cent.—though this is under the mean as given by the authorities named—6250, or 12,500 per 1,000,000, of the population may be expected to die from gastric ulcer or some of its complications. When it is fully grasped that many of the complications can only be dealt with successfully by surgical means and that even in the mildest cases of gastric ulcer some of the most serious complications, such as perforation and hæmorrhage, may suddenly supervene I think that my audience will agree with me when I express an opinion that physicians and surgeons should in the treatment of these serious cases be in closer touch and have a more perfect understanding so that valuable time may not be lost when surgical interference is required. At present I have no hesitation in expressing my conviction that the treatment of gastric ulcer, especially among the working classes, is altogether too careless and unscientific, and I feel sure that the out-patient treatment of such cases, whether in hospital or private practice, is absolutely wrong, and attended with great danger, either of sudden catastrophe from rupture or bleeding, or of the transformation of an acute into a chronic disease which can then only in the greater number of cases be set right by a surgical operation. I think that as soon as gastric ulcer is suspected, the patient should be told the serious nature of the disease and the uncertainty of cure without rest in bed and long-continued care in diet under proper medical supervision. If, then, from business or other reasons, the advice of the medical attendant is ignored, the blame rests on the patient and not, as at present is so often the case, on the slipshod method of aiming at relief and calling it a cure. Fortunately, the surgical treatment of chronic and recurring gastric ulcer and its complications is becoming more and more advocated, and with increasing experience more and more perfect, so that to-day the tale is very different to what it was even a year ago, when I gave a series of lectures on the subject from the Hunterian chair at the Royal College of Surgeons of England. I was then able to collect from all sources 188 cases of operation for chronic gastric ulcer, including 34 cases of my own, but excluding operations for perforation and hæmorrhage. Out of these cases, 31 patients died, giving a mortality of 16·4 per cent., but my recent experience in a largely extended number of cases shows barely a rate of 5 per cent., and as all the patients were either chronic invalids or ill unto death, that means a saving of life in 95 per cent. of the cases, either by gastro-enterostomy, gastroplasty, pyloroplasty, pylorectomy, or gastrolysis.

I must now confine myself to my special subject for this evening, the complication of hæmorrhage, which according to different authorities occurs in a greater or less degree in from 50 to 80 per cent. of all cases of gastric ulcer, and is, according to various authors, fatal when medically treated in from 11 to 3 per cent. (Müller, 11 per cent.; Welch, from 3 to 5 per cent.; Brinton, 5 per cent.: Debove, 5 per cent.; Steiner, 6 36 per cent.; Lebert, 3 per cent.; Dreschfeld, 3½ per cent.; and Rodman, 8 per cent.). If we take the average, 7 per cent. of deaths in cases of gastrorrhagia from ulcer will not be far from the truth. If this is worked out in the 500,000 population of a city like Leeds, it means that of the 25,000 persons who have or have had ulcer, 12,500 suffer from hæmatemesis, and of these 7 per cent., or 875, die. We are, therefore, dealing with a very serious and common accident, and one which a society composed of experienced physicians and surgeons such as are here assembled, can do real good by discussing.

The bleeding may be arterial, venous, or capillary, and curiously, capillary hæmorrhage may be so free as to render it difficult to say that some large vessel has not given way, yet after death a careful examination may fail to discover any gross vascular lesion. Although capillary hæmorrhage may supervene on other conditions, such as congested portal circulation, enlargement of the spleen, and general engorgement of the venous system, when general treatment will usually be all-sufficient, yet there are two special conditions in which the bleeding may be so free as to raise the question of surgical treatment: these are vicarious hæmatemesis at the menstrual period, and post-operative hæmatemesis. The former condition is well recognised and usually yields to medical treatment. Petersen's experience of surgical treatment in three cases terminating fatally after operation would not encourage surgical intervention unless the circumstances of the case were very exceptional.

In my Hunterian lectures I drew attention to post-operative hæmatemesis, of which I have seen several cases; three fatal. The cases occurred after operations for intestinal obstruction, tuberculous peritonitis, herniotomy, and gall-bladder operations. Other cases have since been reported; one by Dr. Winslow in a stout woman, aged 65 years, after operation for umbilical hernia, where death occurred from profuse gastrorrhagia on the third day, and at the post-mortem examination, though the stomach and intestines contained a large quantity of blood, no vascular lesion could be discovered; and another by Mr. C. W. Mansell Moullin in a young man, aged 23 years, who died from profuse hæmatemesis within 48 hours of a simple exploratory incision in the left iliac fossa It was then neither generally recognised nor well understood, but since that time several papers have appeared on the subject both at home and abroad, and though now fully recognised its cause remains obscure. Herr Eiselt ·g tried to explain it as a result of injury to the omentum from several cases observed in the Königsberg Klinik occurring after hernia operations, after operations involving ligature of the omentum. and after torsion of the omentum. Although this explanation may serve as a cause it does not account for all cases, as proved by one of my own, in which a malignant tumour of the common bile-duct causing jaundice and distended gall-bladder was operated on under cocaine, the distended gall-bladder being simply exposed through a small incision, stitched to the parietes and drained, without in any way exposing any other viscera, yet violent hæmatemesis set in the day after operation and proved fatal in three days. This case also disproves

two other theories that have been advanced—one that general anæsthesia is the cause, and another that sepsis affords an explanation, the latter being a theory advanced by Dr. Rodman in his oration before the American Medical Association in June, 1900. That sepsis was not the explanation in the only three cases in which I have had the opportunity of observing the condition after death is undoubted, for in each there was no sign of peritonitis or other septic trouble, and, moreover, there was no gross evidence of ulcer or injury to any vessel of sufficient size to be visible to the naked eye. The theory of sepsis is also negatived by recovery in the greater number of cases and by there being no sign of distension or of the other usual concomitants of septicæmia when it occurs after abdominal operations. The only explanation that seems to me at all feasible is that the hæmorrhage is dependent on a reflex nervous influence, and it is quite possible that this same explanation applies to vicarious hæmatemesis at the menstrual period; but it should also be remembered that slight erosion of the mucous membrane of the stomach sufficiently deep to cause severe gastrorrhagia may be almost imperceptible to the naked eye even when searched for carefully on the post-mortem table. Though serious, it is not necessarily fatal, and I have known several cases to yield to general treatment, such as high injections of hot water at a temperature of from 112° to 116° F., as advocated by Tripier, free purgation by calomel, the stopping of all mouth-feeding and the application of ice to the epigastrium, &c. In post-operative hæmatemesis operation can be seldom feasible or advisable, and Reichard's experience of operations followed by death in two cases would lead me in the future as in the past to rely on general rather than on surgical treatment.

Venous hæmorrhage, if from perforation of one of the large trunks such as the coronary, splenic, or portal, may cause rapid death, but owing to the diminished pressure in the veins and the more languid circulation a rapidly fatal result is less likely than in arterial bleeding, and should the hæmorrhage persist or recur such cases would be likely to benefit by surgical treatment.

Arterial bleeding is mostly responsible for the serious and fatal hæmatemesis due to gastric ulcer. The bleeding may be from the small arterioles which radiate between the peptic glands, from the trunks along the curvatures, the coronary being the most frequently affected, or from extrinsic arteries, the splenic alone being responsible according to Brinton for 55 per cent. of the deaths in fatal hæmatemesis. The following list of 54 fatal cases of hæmatemesis is taken from M. Savariaud's Thesis: Ulcerations of the splenic artery, 17 cases; ulcerations of the coronary artery, 6 cases; ulcerations of the pancreatico-duodenal, 7 cases; ulcerations of the gastric arterioles, 10 cases; branches of the coronary vein, 2 cases; other veins, 2 cases; vessel not determined, 2 cases; no vascular orifice visible, 4 cases; vessel not mentioned, 4 cases. The pancreatico-duodenal and right gastro-epiploic are the arteries chiefly affected in pyloric and duodenal ulcers. The peculiarly fatal nature of hæmorrhages from medium-sized arteries depends on the fact that an ulcer makes a lateral opening into the vessel which prevents natural hæmastasis by retraction and contraction of the artery, the whole force of the heart is then exerted on the clot which tends to form during the syncope that usually occurs when a large quantity of blood is suddenly poured out.

The interval between the first onset of bleeding and death is of great importance surgically and is well shown in the table from M. Savariaud's Thesis which is therefore worthy of note.

Vessel.	No. of cases.	Sudden death.	Rapid death.	Survived considerable time.
Heart	4	1	1	2 (three days).
Aorta	2	—	1	1 (10 days).
Hepatic	2	—	1	1 (10 days).
Splenic	17	3	7	7 (from two to eight days).
Coronary	6	1	3	2
Pancreatico-duodenal	6	1	3	2 (from eight to 15 days).
Arterioles	10	1	1	8 (from four to 15 days).
Small veins	4	1	1	2 (from seven to 11 days).
Invisible veins	3	—	1	2 (21 days).

This table shows that in the present state of our knowledge it is impossible to diagnose the size of the vessel perforated either from the amount of blood lost or the length of survival. A probable diagnosis of the site of bleeding may, however, often be arrived at in hæmatemesis from ulcer by a careful study of the previous history, especially with regard to the site of pain, the time of onset after food, and the influence of posture on it, as well as by the way in which the pain radiates. The situation of the tender spot, the presence or absence of tumour and of dilatation or contraction of the stomach also afford assistance. As will be seen later the diagnosis of the site of the ulcer and therefore presumably of the bleeding is of great importance from a surgical point of view and will influence both the advice given as to treatment and the method of procedure when the abdomen is opened.

TREATMENT.

From the fact that medical and general treatment is successful in arresting hæmatemesis in 93 per cent. of cases, and that it is difficult in the present state of our knowledge to say at first that the bleeding is not occurring from capillaries or small arterioles, it necessarily follows that medical treatment should always have a fair trial in every case of acute hæmatemesis. The very fact of medical treatment being so often successful in cases of apparently alarming hæmatemesis, goes to show that capillary oozing or bleeding from arterioles is much more common and accounts for many more cases of gastric hæmorrhage than has hitherto been supposed. But while thoroughly believing this we must also not close our eyes to the experience we have in general surgery of bleeding from medium-sized arteries, such as the radial or ulnar, which we know would rapidly bleed a patient to death, if only perforated on one side and surrounded by warm compresses, a condition that practically applies in all cases of hæmatemesis where the larger vessels are eroded. If, therefore, medical treatment and rest properly carried out are not successful in arresting the bleeding in a few hours, or if after being arrested it recurs, we should be driven to the conclusion that a large vessel is perforated, and if a surgeon has not been previously asked to see the case, I would say emphatically that a surgical consultation ought to be held with a view to considering the question of operation and immediate arrest of the bleeding by direct treatment if the patient is in a fit condition to bear it, just as would be the case if an ovarian artery were bleeding in a case of ruptured extra-uterine gestation, or a brachial or radial after an accident. The views which I am enunciating to-day are perhaps more pronounced and more emphatic than those which I expressed a year ago in my Hunterian lectures, this being the result of a much extended experience in the surgery of the stomach, a much greater success on all hands in the surgical treatment of stomach diseases and a careful study of more recent statistics.

An analysis of the table by M. Savariaud of 54 cases showing the prolongation of life in various fatal cases of hæmatemesis, demonstrates that in 10 out of 54 cases—that is in 18·5 per cent.—death occurs so rapidly that there is barely time to consider the question of surgical treatment, and that in 17 out of the 54 cases, which equals 31·4 per cent., death occurs within from 24 to 36 hours after the first appearance of hæmorrhage. Now, although at present these cases are often allowed to die without operation, yet if the bleeding were from a radial or tibial or any accessible artery they would all be saved by the simple operation of direct ligature of the bleeding vessel, which operation would also cure the bleeding stomach artery could it be readily found. The difference between the two is, however, not merely only one of accessibility, but also one of diagnosis, for if we are able to diagnose capillary hæmorrhage, the case will be generally one for medical treatment alone, but if the time arrives when we can diagnose with great probability arterial hæmorrhage from a large vessel the case will, I believe, be considered one for the adoption of surgical measures. Our efforts, both as physicians and surgeons, must therefore be directed towards making a diagnosis of the size of the damaged vessel, for if it can be asserted that in all probability a large artery has given way, an operation could be undertaken in an early stage of the case, before exhaustion and profound anæmia have supervened, with great probability of success.

Where there have been distinct signs of gastric ulcer preceding the hæmorrhage and where a sudden hæmatemesis has occurred with great loss of blood accompanied by an attack of syncope, a large vessel will usually be found to be

the source of the bleeding. In all such cases not speedily yielding to medical and general means surgical treatment will probably in the future be carefully considered and in some it will be followed out, for there can be no absolute rule formulated that will apply to every case and each must be considered on its merits. The present condition of the patient, the previous history, the surroundings, the possibility of skilled surgery and of good nursing and other circumstances will all help in the decision. Although both surgical and medical treatment in cases of fulminating hæmorrhage has so far yielded disappointing results, in the remaining 50 per cent. of fatal hæmorrhage where repeated bleedings occur and the interval between the first seizure and death varies from a few days to two or three weeks, medical treatment will have been fully tried and failed and there can be no question as to the advisability of surgical procedures being adopted.

At present with the exception of Dieulafoy, who advocates operation during the first bleeding if as much as half a litre of blood is lost, all other surgeons who have written on the subject agree that general means ought to be relied on during and after a first attack, as in from 93 to 95 per cent of cases such treatment succeeds, and until our means of diagnosis as to the size of vessel injured is rendered more reliable we must assent to this rule; but after a second bleeding I have no hesitation in advising operation even during the course of the hæmorrhage if the patient can stand it or as soon after as his condition will permit the operation to be done, for experience tells us that further hæmorrhages are almost certain to occur unless preventive measures be adopted. I saw a case of this kind last year which created a great impression on my mind. I was asked to see a single woman, close on 30 years of age, with a view to operation after a second attack of hæmatemesis, which had, however, ceased when I saw her, and as the patient, though anæmic, was apparently much easier and expressed herself as feeling well operation was deferred, and a third attack which occurred a few days later during my temporary absence from home proved fatal. In another case I operated during the third attack, found the bleeding vessel, and saved the patient. Doubtless the desirability of stopping bleeding from an ulcer of the stomach by surgical means must have occurred to many minds before being put into execution.

To Mikulicz, however, belongs the claim of having been the first to operate, on Feb. 13th, 1887, for hæmorrhage from a gastric ulcer, though Roux of Lausanne was the first to perform a successful operation, and that in a case of hæmorrhage from the coronary artery in which he excised the ulcer and ligatured the artery at both ends. In my Hunterian lectures I drew up a table of all the cases of operations for hæmatemesis I could then find. It included operations for post-operative and vicarious hæmorrhage, cases not associated with ulceration and all ending fatally. Excluding these and correcting Hartmann's series it would give 26 cases of acute hæmatemesis with 14 deaths and 19 cases of chronic hæmatemesis with two deaths; otherwise a mortality of 53 8 per cent. in acute and of 10·5 per cent. in chronic hæmatemesis treated surgically. A more recent table has been drawn up by Dr. Rodman[1] in which he has collected 32 operations for acute gastrorrhagia with 13 deaths, or a mortality of 40·6 per cent., and 31 operations for frequently recurring, or so-called chronic, hæmorrhages with six deaths, or a mortality of 19·3 per cent., and even since that list was drawn up other operations have been performed. This mortality is very high, but it must be remembered that in every case medical treatment had been first tried, and in many of the cases probably over too long a period before operation was performed; for instance, in one of my cases in which I operated successfully during the third seizure the blood seen at the operation was so diluted and thin as to be more like water tinged with blood than blood itself, yet the bleeding was still going on. Moreover, it is to be remembered that gastric surgery is advancing in safety and efficiency by leaps and bounds and will before long I feel sure, be one of the most satisfactory branches of the surgeon's work.

TECHNIQUE OF OPERATION FOR GASTRORRHAGIA.

On account of the fear of exciting fresh hæmorrhage, it is undesirable to wash out the stomach before operating on a bleeding ulcer, and as the patient is usually anæmic and will therefore bear shock badly it is desirable to have him enveloped in cotton-wool or otherwise kept warm on a heated table and to give him a subcutaneous injection of strychnine before operation. If it be unnecessary to infuse saline fluid before the operation an assistant should be ready to perform that duty while the abdominal operation is being proceeded with should it be called for. After the abdomen is opened the stomach may be emptied by pressing the contents into the duodenum, as suggested by M. Terrier. This saves much time, and rapidity is of great importance. The surface of the stomach should then be carefully examined, as very frequently a puckering of the surface or thickening of the coats will be noticed at the site of the ulcer, or a difference in colour may sometimes indicate its site. Should the operator be fortunately able to find these indications much time may be saved, but if no indications of this sort be obtainable, the stomach must be drawn well forward and opened either by a vertical incision, which gives less hæmorrhage, or by an incision in the long axis of the stomach, which affords a much better view of the interior. In order to avoid soiling the peritoneum, thin flat sponges should be placed within the abdomen and it is well to have a perforated sterilised gauze pad covering the stomach, the opening to correspond with the opening in the stomach. The edges of the stomach should then be held open by forceps, one above and below and one at each end.

The interior of the stomach must now be systematically examined; first the anterior and posterior surfaces, then the upper and lower curvatures, and lastly the pyloric and cardiac orifices, all of which can be done by the naked eye or by the aid of an electric cystoscope or a reflected light. If the posterior wall of the stomach cannot be efficiently examined a slit may be made in the omentum and two fingers, or even the whole hand, pushed through it and employed to invaginate the posterior wall. If no ulcer can be found on the wall of the stomach the duodenum should be explored, not only by the finger but by invagination. If no ulcer be found anywhere and the bleeding proves to be capillary or from small undiscoverable ulcers, gastro-enterostomy should be performed, but if an ulcer be discovered and it be possible to excise it, that operation should be done, as it undoubtedly offers the likeliest method of cure. After excision of the ulcer and ligature of the bleeding vessels the edges of the wound should be brought together by sutures, of which one or two layers may be employed. Should the excision involve the peritoneal coat, it would be desirable to apply Lembert's sutures, and if it be on the posterior wall the operation may present some, though not insuperable, difficulty. Should the ulcer be discovered in some region where excision is impracticable—for instance, near the cardiac end—the method adopted by Mikulicz in his first operation in 1887, of applying the cautery, may be employed. This seems to have answered well in several cases, and where death occurred afterwards it was not from a recurrence of the bleeding. In a case of this kind gastro-enterostomy is also advisable by way of setting the stomach at rest. If any superficial points of bleeding be discovered they may be caught up by forceps and ligatured, but this is more easily said than done, as the mucous membrane is very friable, and a ligature if drawn at all tightly tends to cut its way through; moreover, forceps easily tear the mucous membrane and may produce a larger bleeding area. The method of ligaturing *en masse* may be employed if the ulcer is small; it has proved serviceable in several cases, for instance in Case 5, which will be described presently, and it is easy of application when the ulcer can be reached. It has been tested by experiments on animals by Dr. Eisendrath, but it has been shown to endanger perforation if the serous coat be taken up, except when supported by external sutures. Ligature of the main arteries of the stomach was suggested theoretically by Savariaud when no bleeding ulcer could be discovered; it does not, however, commend itself as being safe or likely to be efficient.

Should the bleeding be from an ulcer at the pylorus the operation of pyloroplasty may be performed, the ulcer being excised and the edges of the gap left by the excised ulcer, as well as the edges of the incision being united so that the line of sutures shall be transverse to the axis of the pylorus. I would not, however, advise pyloroplasty when there is active ulceration of the pylorus unless the ulcer can be completely excised, for in three cases of this kind I have had subsequent disappointments owing to contraction in healing. In one case the patient made a good recovery from the operation but subsequently suffered from stenosis, for which a further operation had to be done. In a second case recovery took place and the patient regained his

[1] Philadelphia Medical Journal, June 9th, 1900.

lost weight, but subsequently a tumour of the pylorus developed which was thought to be cancer and for which I had to perform pylorectomy, and in the third case perforation subsequently occurred. I think, therefore, that in cases of ulcer of the pylorus where a clean excision of the ulcer cannot be done it would be better to perform gastro-enterostomy or pylorectomy, whichever at the time may appear to be easier. Wherever the pylorus is adherent, as in my experience it is in so many cases of ulcer, I should certainly prefer gastro-enterostomy; but if the pylorus be extensively ulcerated and free from adhesions pylorectomy can be almost as quickly performed as gastro-enterostomy, seeing that the pylorus is already in the hand. Although the operative treatment of parenchymatous or capillary hæmorrhage by any surgical method would seem to be of doubtful value—for according to a report by Petersen from Czerny's clinic of three cases operated upon for severe parenchymatous hæmorrhage from vicarious menstruation operation entirely failed to relieve, and in two other cases of post-operative parenchymatous hæmorrhage by Reichard the patients both died—yet if such cases, owing to persistence, seem to call for operation, then gastro-enterostomy, by securing complete physiological rest, would seem to offer the best chance of success.

In performing gastro-enterostomy my recent experience has led me to prefer the posterior operation which I have modified by using my decalcified bone bobbin as a hollow splint over which to apply the double continuous suture, uniting the mucous and serous margins of the openings between the viscera, thus securing an immediately patent channel between the stomach and jejunum and a temporary protection to the line of union. I may say that my last 20 gastro-enterostomies by this plan have all recovered without regurgitant vomiting or other untoward symptoms, thus affording a great contrast to what has occurred in the anterior operation, both in my own and in the hands of other surgeons.

The conclusions I would urge concerning the treatment of gastric ulcer are the following:—1. All cases of acute uncomplicated gastric ulcer should be submitted to thorough medical treatment in the shape of long-continued rest and attention to diet, the patients not being allowed to get up or to resume solid food until at least a fortnight after all disappearance of pain. 2. Where the ulceration persists and proves intractable to medical treatment, or where relapses occur, gastro-enterostomy should be performed so as to secure physiological rest and relieve the hyper-acidity of the gastric juice nearly always found in such cases. 3. Perforation demands immediate surgical treatment. 4. The complications of disabling adhesions around the stomach and pylorus, pyloric contraction, and hour-glass contraction due to chronic ulcers leading to pain, dilatation, loss of flesh, and general impairment of health, now often treated as chronic indigestion, should be treated surgically. 5. In recurring, or so-called chronic hæmatemesis from gastric ulcer, surgical treatment is decidedly called for. 6. In acute hæmatemesis, further accuracy in diagnosis as to the size of the bleeding vessels is urgently needed; and the coöperation of the physician and surgeon is advisable in all cases of hæmatemesis, so that if relief be not obtained by medical and general treatment surgical means may be adopted if the bleeding is believed to occur from a large vessel; but seeing that capillary hæmorrhage is capable of relief by medical means alone, medical should always precede surgical treatment.

The following are brief descriptions of all the cases of hæmatemesis on which I have operated.

CASE 1. *Chronic hæmatemesis; ulcer of the pylorus; pylorectomy.*—In 1891 I was asked by a medical friend to see a man, aged 54 years, who for six months had suffered from pain coming on an hour after food, and more recently from vomiting of blood of coffee-ground character in considerable quantities, so that he was not only reduced in flesh and strength but had been rendered profoundly anæmic by the loss of blood. A tumour of the pylorus could be easily felt and the stomach was markedly dilated. As he was rapidly losing ground I operated and found the pylorus thickened and nodular with adhesions to the liver and omentum. After separating the adhesions the pylorus was excised and the open end of the duodenum was fixed to the opening in the stomach, the rest of the stomach aperture being closed by a double layer of sutures. The tumour proved to be inflammatory around an open ulcer which had been the source of the hæmorrhage. The bleeding was not repeated and the patient rapidly gained flesh and returned home within the month.

CASE 2. *Hæmatemesis following on a stab wound of the abdomen; abdominal section.*—On Jan. 27th, 1897, a young mechanic, aged 20 years, was admitted to the Leeds General Infirmary under my care with free vomiting of bright blood following on a stab wound of the abdomen, the wound having been inflicted by a long fine triangular file that had caught in the lathe at which the youth had been turning. On admission he was pale and collapsed, with a pulse of 190, and as there were signs of free fluid in the peritoneal cavity, it was thought that the stomach had been perforated and that the bleeding was from a ruptured gastric artery. On opening the abdomen a large quantity of blood and clot was found free in the abdominal cavity and in the kidney pouches and pelvis, but on examining carefully the stomach no perforation could be found. After some searching the superior mesenteric vein was found bleeding freely, the file having bruised and pushed aside the stomach, pierced the great omentum, and then wounded the vein. The abdomen was washed out with hot water after the vein had been ligatured, and this also arrested the gastrorrhagia, as the patient made a good recovery and had no further hæmatemesis. The shock was relieved by infusion of three pints of normal saline solution into the median basilic vein and by injection of liquor strychniæ. The bleeding was evidently from bruising, and possibly laceration, of the mucous coat of the stomach and not from a large vessel, as it was arrested by the hot lavage.

CASE 3. *Acute hæmatemesis from ulcer of the duodenum eroding the gastro-duodenal artery; anterior gastro-enterostomy with Murphy's button.*—I was asked by my colleague, Dr. T. Churton, to see a man, aged 36 years, who after a year's history of ulcer of the stomach with great loss of flesh and strength was suddenly seized with profuse hæmatemesis, which was followed in 24 hours by a second seizure, when I saw him. He was then extremely weak and very thin and anæmic and looked as if he must die if further hæmorrhage occurred. His pulse at the time of operation was 150. The history clearly pointed to the pylorus as being the seat of bleeding, but the patient was too ill to bear pylorectomy and an anterior gastro-enterostomy was performed by means of a Murphy button, the whole operation only occupying 15 minutes. He bore the shock well and for five days made good progress, but on the sixth day he was suddenly seized with severe abdominal pain, and from that time he lost strength; vomiting set in on the eighth day and he died on the tenth. No further bleeding occurred and at the necropsy a duodenal ulcer opening into the gastro-duodenal artery was found. The cause of death was peritonitis, the result of the leakage when the button began to separate. So far as the hæmorrhage was concerned the gastro-enterostomy had been completely successful, and the vessel, though perforated at one side, was occupied by a firm clot.

CASE 4.—A man, aged 44 years, was sent to me by Dr. P. Macgregor of Huddersfield, on Jan. 2nd, 1900, with the history that he had had pain after food together with other symptoms of gastric ulcer for four years, though his first attack of vomiting blood occurred in May of the previous year. The bleeding was rather profuse, but under medical treatment and rest he recovered and was able to resume his occupation. A week before he was sent to me there had been a recurrence of the hæmorrhage which was repeated three days later. On his arrival at the surgical home he was in a state of collapse with a barely perceptible pulse. There was well-marked dilatation of the stomach with tenderness over the pylorus. The history of the pain occurring one and a half hours after food, together with the site of the tenderness and the presence of a large amount of blood in the motions, left no doubt but that the ulcer was at or near the pylorus. As the bleeding had recurred twice in the week and was probably persisting and passing into the bowel, operation was decided on. This was done on the 4th. As the patient was in such a feeble condition every precaution was taken to guard against shock, and it was decided only to perform gastro-enterostomy as it was quite clear that he could not stand any prolonged search for the bleeding point. A posterior gastro-enterostomy was therefore done, a decalcified bone bobbin being used to make the anastomosis. His temperature and pulse were never above normal and he made an uninterrupted recovery. He was fed by nutrient enemata for the first few days, only taking sips of water by the mouth, but at the end of that time he was allowed to

take milk and soda water, and then gradually to have stronger food. He was up at the end of the third week and returned home within the month. A year later he was in perfect health and had had no recurrence of his stomach symptoms or any further bleeding.

CASE 5.—On July 6th, 1900, I was asked by Dr. G. P. Humphery of Armley to see a female patient, aged 33 years, who had been seized with violent hæmatemesis a week previously, the attack having recurred four days later and again on the day when I saw her. The patient had been anæmic before operation and had had some slight indigestion, but otherwise she did not consider herself ill, and she had been married only three months. On my arrival I found her quite blanched and with a very rapid, feeble pulse, but as the bleeding had resisted ordinary remedies and as she would clearly die if unrelieved, though it seemed a rather desperate procedure, we decided to give her the chance of relief by operation. She was removed by ambulance to a surgical home, and as during the journey the bleeding began again I operated without delay. A pint of saline fluid containing one ounce of brandy was given into the rectum and 10 minims of liquor strychniæ were administered just before the operation, the patient being completely enveloped in cotton-wool. On opening the abdomen there were no indications on the surface of the stomach as to the situation of the bleeding ulcer. I therefore made an incision in the axis of the stomach which enabled me to explore the interior. I counted no less than seven bleeding points. As two of them were bleeding freely I took them up by artery forceps and ligatured the mucous membrane *en masse;* the other points stopped on exposure to air. I then rapidly closed the wound in the stomach and performed posterior gastro-enterostomy, using one of my bone bobbins as a splint over which to make the anastomosis. We had a little anxiety on account of shock for the first 24 hours, but by administering saline fluid by the bowel and injecting it freely into the subcutaneous tissue, together with the administration of several injections of liquor strychniæ, the difficulties were tided over and the patient's further progress towards recovery was uninterrupted. She was able to take solid food in the second week, and when she left at the end of the month she could eat any ordinary food without discomfort. Six months later she had no recurrence of symptoms and was well in every respect.

Five is not a large number of cases to report, but the treatment of hæmatemesis by operation is a comparatively new operation, and only few cases have been reported. Had it not been for the accident of leakage when a Murphy button was beginning to separate there would have been no casualty in the list, and that is an accident which is avoidable by employing sutures around a decalcified bone bobbin, as is now my regular custom. Undoubtedly without operation all the patients would have died. The cases present individual points of interest. In Case 1 a pylorectomy was performed as the pylorus was the site of a tumour that might have been malignant, though could it have been asserted that the enlargement was simply thickening around an ulcer gastro-enterostomy would have answered equally well, as it did in Case 3 and Case 4 by securing physiological rest and freedom from the irritation due to hyper-acidity of the gastric juice which is usually present in ulcer of the stomach. In Case 2 hot lavage acted in the same way as it does when given by high injections into the bowel, only in this case it was necessary to open the abdomen to search for and to ligature the large vessel bleeding into the peritoneum. Case 5 illustrated the feasibility of exploring the stomach even in a patient brought very low by excessive loss of blood, and although the ligature of the chief bleeding points was effected it was deemed advisable to secure rest to the stomach by performing a posterior gastro-enterostomy, especially as it could be done without materially prolonging the operation.

It only remains for me to thank you for giving me such a patient hearing and to hope that the discussion which is to follow may prove of interest to the society and to the profession at large.

NEWPORT WORKMEN'S INFIRMARY FUND.—At a meeting of the committee of the Newport (Mon.) Workmen's Infirmary Fund held on Jan. 29th it was reported that £1317 had been received during 1900 £1000 were transferred to the infirmary, leaving a balance of £266 in hand after sundry payments.

The Baillie Lectures

ON

CONSIDERATIONS TOUCHING THE PATHOLOGY AND RELATIONS OF DIABETES.

Delivered at St. George's Hospital on Dec. 5th and 12th, 1900,

BY W. HOWSHIP DICKINSON, M.D. CANTAB., F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET; HONORARY FELLOW OF CAIUS COLLEGE, CAMBRIDGE.

LECTURE II.[1]

Delivered on Dec. 12th, 1900.

GLYCOGENESIS.

GENTLEMEN,—Some of the mystery which surrounds diabetes will be dissipated when we have come to a common consent about the bearing of the liver upon sugar. When Bernard made his famous research more than 50 years ago a sudden light was thrown upon glycosuria which led to the expectation that all would be soon made clear. But this hope has not been justified. We seem to be within sight of a great discovery without knowing exactly where to seize it. The spirits of the wise sit in the clouds and mock us. The time will come when all the disjointed fragments of the puzzle will be fitted together and those who look back upon the accomplishment may say, How easy, how obvious, and how strangely missed!

The liver is the great, though not the only, seat of the making of glycogen. As to the making of sugar there is more to be said. The liver receives by the portal vein what the veins take up from the alimentary canal, passes it through its own capillary system, with results which are still *sub judice*, and discharges the whole by the hepatic vein through the pulmonary into the general circulation. Certain parts of the food, notably the carbohydrates, are arrested in the liver and converted into glycogen or animal starch. This was discovered by Bernard and is admitted by all. The next step is upon debateable ground. Bernard supposed that the glycogen was converted in the liver into sugar and discharged as such into the blood. Thus the liver, according to Bernard, makes sugar out of glycogen and feeds the blood with it. This view is diametrically opposed by Pavy who considers that the liver, in making glycogen out of the carbohydrates, keeps sugar out of the blood. In Bernard's view the liver is a sugar-making organ, in Pavy's a sugar-arresting organ. Both these physiologists agree in looking upon diabetes as the result of too much sugar being put into the blood; they differ in the respect that according to Bernard too much is put in, according to Pavy too little is kept out. In Dr. Pavy's own words the sugar in diabetes is allowed to pass through which ought to have been arrested and assimilated. I will not presume to decide between these conflicting opinions. Both must be treated with respect. Bernard was the greatest physiological genius of the nineteenth century. Pavy has spent a long life of unremitting labour in a field of inquiry wherein he can scarcely be supposed to have toiled in vain. For the present we must halt between the two opinions, but it cannot be for long.

That the blood in diabetes contains too much sugar is undisputed. Theoretically this may be either because too much gets in or because too little is taken out. In both the views which have as yet been stated too much gets in, but it behoves us to glance at the other possibility. If any sugar reaches the blood in health, which Pavy contends is not the case, it is used up, since none, or practically none, escapes with the urine. Supposing it to reach the blood, to what use is it put? Bernard first thought that it was burnt in the lungs, afterwards that it was consumed in the systemic capillaries—in other words, by the tissues. It is clear that if any sugar enters the blood in health it is disposed of in

[1] Lecture I. was published in THE LANCET of Feb. 2nd, 1901, p. 299.

the body, since none leaves it excepting under disease. It has been supposed by some that the accumulation of diabetes is due to insufficient removal rather than superabundant introduction. In this view the tissues fail to take up their due of sugar, which accordingly remains in the blood. This failure, however, supposing it to occur, must be quite inadequate to account for the enormous amount of sugar which the blood, in cases of severe diabetes, pours into the urine. This may come to over two pounds a day, a quantity which cannot be explained otherwise than by over-production of the article. It is impossible to suppose that the normal appetite of the tissues for sugar, if such there be, could account for so large a consumption of this aliment. We must conclude that diabetes depends on too much sugar being put into the blood rather than on too little being taken out, and the question narrows itself as to whence this is derived. I have already referred to Bernard's view that under diabetes too much sugar, or sugar instead of glycogen, is made in the liver. I must dwell for a moment on Pavy's contention that instead of too much being made too little is kept back. Pavy[2] holds that the carbohydrates of the food are, in health, prevented from reaching the general circulation by three modes of arrest: (1) conversion into fat before they reach the liver, mainly in the villi of the intestine; (2) conversion into proteid by means of superadded nitrogen; and (3) transformation into glycogen in the liver.

The failure of all or of any of these modes of turning the sugar into something else would, in this view, lead to its entrance into the general circulation and its discharge with the urine. In one view the liver has all to do with the diabetic process; in the other view something to do with it. Here I leave the question to the arbitration of the future with only this remark—whatever view physiologists may hereafter agree upon they will have to take into account the connexion of glycosuria with the nervous system as shown experimentally in animals, traumatically in man, and as the result of certain mental states and impressions. We know nothing of the action of the nervous system upon the villi or upon the building up of the carbohydrates into proteid, but we cannot doubt that the function of the liver is regulated by its nerves. All glands are under nervous control, and of two kinds—exciting and inhibitory. It is to be presumed that the sugar-puncture acts especially upon the liver, and that through its nerves, whether in the way of excitement or restraint. As a provisional theory, or hypothesis, which is probable though unproved, we may accept that which connects human diabetes, or at least the commonest form of it, with a morbid influence directed upon the liver from the brain.

It is probable that the glycosuric action in connexion with puncture is of the nature of irritation not of paralysis. For the sugar presents itself while the injury is recent and disappears when the immediate effect has subsided, before there has been time for any structural repair. What nerves are irritated is another question; there are nerves which promote glandular action and others which restrain it. Whether the irritation be of a kind to excite or inhibit may be regarded as uncertain. It is conceivable that the irritation may act by preventing the proper development of glycogen and allowing its elements to pass as sugar without that intermediary. On the other hand, it is possible that the morbid influence may cause the glycogen, after being properly formed, to run into sugar instead of being applied to other uses.

I have alluded to certain states of mind, or, in other words, of brain, as productive of diabetes. Grief, anxiety, and terror are noticeable in this relation. How these act we know not. If we require the satisfaction of a phrase we may say by means of cerebral irritation.

It is apparent, speaking superficially, without speculating on ultimate and hidden causes, that there is more than one kind of diabetes, or rather diabetes of more than one origin. Facts have come to light with regard to the pancreas which our present knowledge does not suffice to explain but which will have to be taken into account in any comprehensive view of diabetes. It has been shown that complete removal of the pancreas in the dog is followed by persistent and fatal glycosuria. If the removal be incomplete no such result follows nor does it follow if a piece of the organ be transplanted to another part of the body. The duct may be tied without any result in glycosuria which does not ensue so long as any portion of the pancreas is in vascular connexion with the system. It would seem that the pancreas, apart from its secretion, does something to the blood which in conditions of health restrains the formation of sugar. Many instances have been brought to light in which disease of the pancreas in the human subject has been attended with diabetes, fibroid and fatty degeneration, cancer, and calculi.

In diabetes there is much room for speculation, hypothesis, and error. Provisionally it may be suggested that the pancreatic origin of this disease is not necessarily inconsistent with its more frequent origin in the brain and the liver. It looks as if the carbohydrates were always tending to run into sugar and needed prevention at every stage. Hepatic glycogen passes rapidly into sugar as a post-mortem change. It is restrained from doing so above measure during life and health, presumably by an influence directed upon the liver by its nerves. Every dead man should be diabetic could he feast up to the moment of departure and secrete urine afterwards. There may be other stages at which the carbohydrates tend to slip into sugar if not prevented; one of these may be in the systemic blood, and the pancreas be the withholding agent. It may be that the saccharine conversion needs to be bridled in two places, the liver holding one rein, the pancreas the other. But I know the stigma which attaches to those who rush in where their betters fear to tread, and will quit the dark paths of physiology, which are not within my beat, for the familiar march of practical medicine where the concrete supersedes the abstract, where experience takes the place of experiment, and where science, often falsely so called, must ever submit to the correction of the wards and the dead-house.

The chief purpose of pathological research is to direct or withhold us in the treatment of disease. In this view the treatment of diabetes gains little from pathology. We must presume that the disorder depends on a lesion which is unknown in its fundamental part though converging evidence assigns it to the nervous system. We have reason to believe that the essential lesion is not to be cured though some of its effects can be obviated. We can treat the symptoms and results but not the disease. The most characteristic of these is glycosuria, and it may be added that it is the one most amenable to therapeutic measures. The discovery of Rollo, an army surgeon whose name suggests other adventures than with sugar and starch, is the basis of the scientific treatment of diabetes; not that this comprises the whole problem but only the first part of it. In early or slight cases the removal, even the partial removal, of sugar and starch from the diet may accomplish the removal of sugar from the urine; but in more advanced or severe conditions the glycosuria will persist notwithstanding that the food be deprived of these carbohydrates with the greatest attainable strictness. It seems that in mild or incipient cases the sugar which finds exit is only that which is introduced into the body as sugar or starch; in the more severe or advanced cases the sugar is formed at the expense of the nitrogenous constituents of the blood. The albumin is broken in two, one fragment being sugar, the other urea. Both make their way out by the kidneys. Thus the albumin, the chief nourisher in life's feast, becomes, so far as the disease seizes it, wholly excremental and feeds the urine instead of the body. "Hydrops ad matulam" is an old and not inappropriate name for the disease. The language sometimes

[2] Dr. Pavy has kindly enabled me to append in his own words an abstract of his views as contrasted with those of Bernard. "The position," writes Dr. Pavy, "may be thus expressed: Under Bernard's view the carbohydrate of the food reaches the general circulation as sugar and is conveyed to the tissues for oxidation. A portion in its transit through the liver is temporarily detained as glycogen to be reconverted into sugar and sent to the tissues as needed. I hold that there is not this transit of sugar through the circulation, from the food to the tissues, in a free form. The sugar in the blood, which is only small in amount compared with what was formerly supposed, I regard as a constitutional ingredient just as exists in all the tissues of the body and unconnected with the application of alimentary carbohydrate. It is not influenced in amount by the nature of the food; it does not perceptibly vary in amount in different parts of the general circulation; and it is present after prolonged fasting even after glycogen has disappeared completely from the liver and tissues. Looking at all the existing circumstances it is not conceivable that this sugar is being drawn upon for direct oxidation purposes, but that it rather serves as a pabulum in connexion with nutrition. The trace of sugar found in healthy urine harmonises with the condition of normal blood. I consider that the carbohydrate of food is disposed of—(1) by conversion into fat, (2) by synthesis into proteid, and (3) by transformation into glycogen, and is thus prevented from reaching the general circulation as sugar. When such is the case the urine remains uninfluenced, whilst if the carbohydrate should not be thus fully disposed of, that which escapes being disposed of will reach the general circulation as sugar and thence escape as waste material with the urine. For the urine to be kept free from sugar the sugar must be kept out of the blood."

employed would seem to convey that in mild cases the sugar is derived from the food, in severe cases from the tissues. It is obvious that in both cases the sugar in the urine is derived immediately from the blood, which is the only source of the renal secretion. In cases of the milder type the carbohydrates only are thus perverted; with the more severe cases the nitrogenous part of the blood is destroyed and excreted. The blood is mainly supplied by the food, probably only to a comparatively small extent by the disintegration of the tissues, and we must suppose that diabetic sugar is chiefly derived from the food, though it is not possible to deny that the waste of the living structures may contribute towards it. It is obvious that no restriction of diet can stop the excretion of sugar so far as this is derived from the albumin, but if only from the carbohydrates it may be put a stop to by their withdrawal. Whether the disease be slight or severe it equally concerns the carbohydrates, notably the sugar and starch; if severe it seizes the nitrogenous constituents of the blood plus the carbohydrates.

It has been supposed that certain toxic matters which are found in the urine in severe diabetes, such as acetone, diacetic acid, oxybutyric acid, and are in some sort a measure of its severity and peril, are derived not so much from the food as from the tissues of the body. At any rate they appear to be to a certain extent controlled by diet, though in severe cases the strictest exclusion of the carbohydrates though it may diminish will not exclude them. In such cases it is clear that these toxic products are derived, as in the sugar, from the disintegration of the nitrogenous products, whether of the food or the frame, probably chiefly of the food.

By diet we can always lessen the diabetic perversion even where we do not abolish it. Diet, putting aside exceptional circumstances, always does good, though not always all the good that is required. It is not necessary that I should inform this audience that the avoidance of sugar and starch is the guiding principle of diabetic diet, nor do I propose to weary you with a list, for such may be found in any text-book relating to the subject, of what the patient should eat, drink, and avoid. The sufferer from diabetes has a large liberty in the way of food. It is true that bread and water would not suit him, but so long as he keeps out of jail and avoids fasting, whether entailed by piety or poverty, he may do well. He may dine with a city company and so long as he does not take bread or potatoes feast like an alderman. The substitutes for ordinary bread present the chief difficulty. Gluten bread is theoretically correct, but some patients cannot get it down; they say it is like chewing india-rubber. But the gluten flour need not be made into bread, and it is often less objected to in other shapes which can be given to it in the domestic kitchen, cakes, buns, and puddings. Bran biscuits often do well and are useful, as they tend to obviate the constipation which is one of the troubles of the disease. Green vegetables—spinach, French beans, and the like—are fully recognised as fit for the diabetic; but I may mention some vegetable products which are not green and yet are of especial use in diabetes: I refer to vegetables containing much cellulose. It is true that cellulose is a carbohydrate, but it does not appear to be easily converted into sugar, and indeed it is doubtful whether in the human body it undergoes any such conversion. One of the troubles of diabetes is constipation; cellulose largely passes off in the fæces and tends to obviate this condition. The more bulky varieties of garden stuff, whether roots or fruits, may be made use of, such as cucumbers, vegetable marrows, tomatoes, and radishes. Apples, if not obviously sweet, may be permitted in small quantity. These articles of diet are not all absolutely free from sugar, but none contain much sugar, and certainly they are often useful, though perhaps not absolutely correct in theory. Anything is better than nothing, and if the diabetic cannot take what he should he had better take what he can.

It is of importance, even of vital importance, not to overdo the restrictions or to be too sudden in their introduction. In mild cases, where a minor degree of deprivation will suffice to remove the sugar from the urine, do not push it further. Milk, which as containing sugar of milk is theoretically inadmissible, is often normally assimilated when cane sugar is not. If milk is found not to increase the sugar in the urine it should be freely given. As to water, let the patient drink as much as his thirst demands. If there be any threatening of diabetic toxæmia, the more he drinks the better, to wash out the cause of offence. That the liberal introduction of water into the blood exerts a purifying action upon it and relieves it, if only for a time, of some of the toxic products of the disease, is evident from the marvellous though temporary emergence from diabetic coma which has been known to follow aqueous injections into the veins. Probably the water acts by increasing the excretions and assisting the exit of the diabetic poison.[3]

With diet as the fundamental part of the treatment of diabetes we may next come to the accessories. Of these opium and its constituents demand the first consideration. That opium, morphia, and codeia lessen the excretion of sugar is certain, a result which is consistent with the hypothetical origin of the disease in nervous irritation. The use of opium in diabetes was introduced, so far as I know, by Pelham Warren, physician to St. George's Hospital and to King George the Fourth. The paper may be found in the Medical Transactions of the College of Physicians for 1812. Dr. Pavy[4] refers to a Dr. McGregor as having placed on record in 1837 two cases of diabetes treated with opium as if the practice had been invented by him or were then a novelty, but I do not observe that Dr. McGregor makes any such claim himself though he does not mention Pelham Warren by whom he was anticipated in this use of opium by exactly a quarter of a century. Not that opium had never before been given in diabetes, though I suppose never before Warren's time was it credited with any special action in this disorder. Aretæus recommends the Theriaca of Mithridates,[5] of which one of the ingredients was opium, as of use in diabetes; but as this celebrated medicine contained 72 drugs it is difficult to know to which to attribute any good which it did, if, indeed it did any. As a modern and working practice I presume that the use of opium in diabetes belongs to Pelham Warren, though whether he has done more good or harm in this respect is an open question. That opium controls glycosuria is certain; that in severe diabetes a remarkable tolerance of opium is often manifest is apparent; but that opium cures diabetes or can be in general beneficially used in its treatment is a question. Opium disturbs the normal functions and often upsets the general health. Diabetes is attended with constipation which opium makes worse; one of the chief dangers of the disease is the special and fatal form of coma which the careless use of opium appears to invite. Of late years I have practically given up opium and codeia in the treatment of diabetes, and my impression is that my patients have lived longer without them than they would have done with them. If it be determined to make trial of one of these drugs I would, at any rate, urge its association with something that will antagonise its constipating effect: a few grains of compound rhubarb pill or a minute quantity of extract of colocynth or of podophyllin with each dose of the opiate and an occasional clearance with a mercurial.

Are we to do nothing, then, for diabetes save in the way of diet? Not quite this, though diet is of all things the most important and neglect is better than over-medication. I have no doubt that good is often done by the nerve tonics, especially strychnia, in favour of which I have nearly abandoned all other remedies of this class. Liquor strychniæ can be associated with tartrate of potash without fear of precipitation, though not with the alkaline carbonates. I have been in the habit, perhaps on insufficient reason, but with some aim at the nervous system and as I have thought with good result, of adding a few grains of phosphate of potash which, though it may serve no other purpose is a laxative. Diabetes is sometimes associated with gout and with excess of uric acid. Alkalies are of use in such cases. I must revert for a moment to another remedy which is called for both in gout and in diabetes, and that is water, soft water for choice—the universal solvent and eliminant, an eliminant that may postpone the coma which it cannot cure. The benefits of water-drinking and of alkaline or saline medication are combined in some of the baths to which diabetics resort, notably Carlsbad, the water of which contains chiefly sulphate of soda. No doubt Carlsbad water sometimes does good, and the air, the exercise, and the diversion may do good too. But before we send people to a foreign country let us make sure that they cannot get what they want at home. Travel and change are often in themselves remedial; but travel, if sometimes a

[5] Paris's Pharmacologia, ninth edition, p. 78.

remedy, is sometimes an aggravation, and change is good when not for the worse; but the ills we know not of may be unwisely preferred to those we have.

Mineral waters contain many ingredients, some possibly good for the disease it is desired to benefit, some, perhaps, the reverse; let us find out what is required and give it without admixture or contamination. The chief remedy conveyed by every spring is the *water*, using the term in its chemical sense; we have plenty of water at home and that of the best. With regard to mineral springs, these are mere geological accidents; there was no thought of us, of the action of our livers or of the state of our urine, when the cracks in the earth's crust began to discharge their rinsings. Here is a spring, let us say, which tastes of brimstone and comes up hot, suggesting a greater proximity to the infernal regions than would generally be thought a recommendation. No beast will touch it. Man is more adventurous or more confiding. No sooner does he become aware that a certain spring yields water of exceptional impurity than the happy thought occurs to him, "Let us drink some." A course of mineral water is spoken of as a "cure," though possibly the patient may find his disease made worse thereby. Many a calculus, instead of being dissolved or expelled as the credulous proprietor was led to expect, has become the seat of fresh deposit and diversified stratification. A person with an incurable malady will go about from one "cure" to another enjoying, if nothing else, the pleasures of hope. Among the constituents of Carlsbad water are, according to Pereira, soda, lime, magnesia, alumina, manganese, iron, and silica in combination with sulphuric, hydrochloric, phosphoric, and fluoric acids. The time will come when we shall know which of these does good in diabetes and give it, or them, in a pure solution instead of the chance medley of a mineral spring. All we should ask of our location would be pure water in which to dissolve the essential salts. We should not be tied to a gushing fissure but might seat ourselves wherever air, scenery, and season indicated. And those who preferred to stay at home would find at home the salutary drink though not the salutary surroundings. But this is looking too far ahead; perhaps by the millennium we may have developed some such system of pure science and become able to deal with abstract properties, but at present we have to take things mixed and to do our best with barbaric methods. In Utopia, where the air and the water are the purest known, are places of easy resort where cunning chemists prepare the exact solutions suited to every ailment which is to be benefited by water. A series of taps dispense to every ailment its appropriate remedy. The gouty, the rheumatic, the rheumatoid, and the diabetic are each supplied with the precise drink which will do for him all that a drink can do. The glutton and the sot drink out of neighbouring channels and both are made ready for fresh excesses; while he who has taken too much out of himself finds his balance duly adjusted as well as he who has put too much in. Inspiriting adjuncts are provided, not omitting the "fiddlers three."

I have taken a retrospective view of our knowledge concerning a very common and very obscure disease, having regard to what we think we know and humbly confessing that what we do not know is assuredly the more important part. If such a sketch as I have attempted comes to the notice of the Baillie Lecturer of 1900 years hence it may appear to him to be inadequate and erroneous, perhaps even to a ludicrous extent. It is probable that minute morbid anatomy will by that time have been carried far beyond anything within the reach of our rude methods and our imperfect instruments and that modes of action within the body which now admit of doubt and dispute may then be so clear as to afford no scope for either. The wise man of the future whose topic is diabetes will know what importance to attach to such evidences of disturbed circulation as have been found in the nervous centres and may possibly be aware of other changes in them as yet unknown. He will know something of the way in which mental impressions fill the blood and the urine with sugar and why a lesser degree of the same contamination is a concomitant, though an infrequent one, of lunacy. The extravagant excretion of phosphate of lime in diabetes will be fully understood and the loss of the patella reflex will present no doubts as to the nature and the cause of the nervous lesion which it indicates. As to the treatment in the future it is unsafe to speculate, but we may with some confidence predict that it is more likely to rest upon improved physiology than upon the empirical use of drugs. As to mineral waters, I suspect that they will be resorted to in the future as in the past and that the chance mixture which nature provides will long be preferred to anything which the most accomplished physician, aided by the most accurate chemist, can design.

Three Lectures

ON

THE SURGERY OF PREGNANCY AND LABOUR COMPLICATED WITH TUMOURS.

Delivered at the Medical Graduates' College and Polyclinic on Jan. 11th, 18th, and 25th, 1901,

BY J. BLAND-SUTTON, F.R.C.S. ENG.,

SURGEON TO THE CHELSEA HOSPITAL FOR WOMEN; ASSISTANT SURGEON TO THE MIDDLESEX HOSPITAL.

LECTURE I.

Delivered on Jan. 11th.

PREGNANCY AND LABOUR COMPLICATED WITH OVARIAN TUMOURS.

GENTLEMEN,—Anything which jeopardises the life of a woman when she is advanced in pregnancy, but more especially when she is enduring the "pain of childbirth," always excites our deepest interest and sympathy quite apart from the fact that two lives are involved. This being so I shall begin this lecture by briefly stating the details of two cases which will well illustrate the grave dangers which beset the life of a mother and of the child when, after being some hours in unavailing travail, it is discovered that her pelvis is occupied by a tumour.

CASE 1.—On Oct. 3rd, 1900, a woman, aged 28 years, had been in labour with her first child for about 20 hours. She was then seen by Dr. A. B. Calder who found delivery obstructed by a large, tense, semi-fluid mass occupying the outlet of the pelvis. He at once recognised the gravity of the case and had the patient conveyed to the Chelsea Hospital for Women in a cab. I happened to be at the hospital when she arrived and quickly satisfied myself that the hollow of the sacrum was filled with a large, tense, cystic mass which completely occupied the true pelvis. We at once arranged for speedy relief The abdomen was carefully washed and made as antiseptic as possible in the circumstances and the patient was etherised; the uterus was exposed by a free incision in the linea alba and an attempt was made to extract the tumour. The head of the fœtus was so thoroughly impacted in the pelvis that I could not even insinuate a finger between the uterus and the pelvic brim; under these conditions I incised the uterus and extracted the fœtus with its placenta and membranes; this enabled me to reach the cyst and to withdraw it from the pelvis. As is always the case in such circumstances, it had a long and slender pedicle which I ligatured with thin silk in the usual manner. The incision in the uterus was closed with two layers of silk sutures, one set including the mucous and part of the muscular wall, the second including the serous layer and subjacent portion of the muscular wall of the uterus. The incision in the linea alba I closed in three layers. The vagina was thoroughly irrigated and the patient, who had lost very little blood, returned to bed in excellent condition. The infant, a vigorous boy, "wauled and cried" as usual on his advent into the atmosphere, and on the second day he took the breast in the ordinary way and throve as usual. The mother convalesced with as little difficulty as after normal labour. I considered it desirable to keep her resting in bed for three weeks to allow the uterine, as well as the abdominal, incision to heal soundly. The tumour was a dermoid with a single cavity filled with the usual pultaceous matter mixed with shed hair and containing one piece of bone. It was somewhat ovoid in shape, its axes measuring ten centimetres by eight centimetres. The consistence of the contents of the dermoid was about

equal to that of soft soap, so that under the pressure of the strong uterine contractions it had become very accurately moulded to the cavity of the true pelvis.

CASE 2.—On July 29th, 1896, a friend of mine, a practitioner with extensive experience in midwifery, asked my advice in regard to a woman, aged 33 years, the mother of two children, in travail with her third child, but delivery was obstructed by a pelvic tumour. I advised him to send the patient into the hospital without delay so that ovariotomy could be carried out. Instead of this he obtained the assistance of another practitioner and they succeeded in pushing up the tumour and extracting the child with forceps. On August 2nd—that is, the third morning after delivery—the patient had severe pain in the abdomen, accompanied by vomiting, an accelerated pulse, and high temperature. This naturally caused alarm; my friend came to me and described the treatment that had been adopted and which I have just described. The patient was admitted into the hospital in an extremely critical condition; the abdomen was greatly distended and tender, the pulse rate was 150 to the minute, the temperature was 100° F., and the patient looked extremely ill and vomited frequently. I gently examined the abdomen but could not distinguish a tumour and I came to the conclusion that it had in all probability been burst when it was pushed out of the pelvis. This conjecture, however, proved to the erroneous. The patient's condition, though clearly desperate, was not entirely hopeless, and it seemed cowardly to abandon the poor woman to her fate, so I performed cœliotomy. On incising the abdominal wall a large quantity of muco-purulent fluid escaped and the intestines were villous with patches of inflammatory lymph. An ovarian tumour of the dimensions of a fœtal head was detected and removed; its pedicle was twisted through one complete revolution. No signs of injury were observable on the uterus or in the pelvis. The exudation was carefully removed and the wound was secured in the usual way. The operation failed to improve matters and the patient died 18 hours later. A very thorough post-mortem examination failed to throw any light on the cause of the peritonitis. The tumour was a semi-solid ovarian adenoma.[1]

These two cases deserve careful consideration, for whilst the issue in each instance is in striking contrast the method which I adopted in the successful case is by many regarded as distinctly unorthodox, inasmuch as it is contrary to authority and tradition, whilst the ancient method adopted in Case 2, which resulted in the death of the child and subsequently involved the life of the mother, has the sanction of some practitioners who make midwifery the principal work of their lives.

The subject is specially interesting to me because when preparing the second edition of my book on "Surgical Diseases of the Ovaries and Fallopian Tubes" I accumulated a quantity of records from a variety of sources and analysed them in regard to this particular point, and although I was able to work out certain principles for my own guidance it is quite clear from a study of some of the "remarks" made on the subject that the Fellows of the Obstetrical Society of London are very uncertain which is the best way of dealing with this serious difficulty.

Let me first show you how uncontrolled nature acts in such an emergency as is set forth in these two cases—that is, when an ovarian tumour occupies the pelvis and offers mechanical impediment to delivery. In such circumstances the fœtus almost invariably dies and the following accidents may happen: (1) rupture of the cyst; (2) rupture of the uterus; (3) rupture of the vagina; and (4) extrusion of the tumour into the rectum. This is a formidable list of dangers and, extraordinary to relate, with the exception of rupture of the uterus women have recovered even under such awful conditions. It will serve my purpose very well briefly to refer to some of the more important of them, as it will enable me to indicate in precise terms the disadvantages of some of the methods of treatment which are still advocated.

Rupture of the uterus.—This, I believe, is a somewhat exceptional accident under these conditions, but the best known case was recorded by Ogier Ward[2] in which a cyst of the right ovary as large as a cocoanut prevented the head of the fœtus from entering the true pelvis. The uterus ruptured and the woman died.

Rupture of the vagina.—This is an unusual accident when it occurs as a result of the efforts of the uterus alone. One of the best-known examples is that recorded by Kerswill. A woman in labour was found to have an obstruction in the pelvis. In the course of the delivery an ovarian cyst of the size of a cocoanut was detached and forced through a rent in the vagina. Five centimetres of the pedicle remained on the tumour. The patient recovered.[3]

Extrusion of the tumour into the rectum.—One case has been observed and recorded in which an ovarian dermoid obstructing labour has been pressed into the rectum and the wall of the bowel has become invaginated and the tumour, invested by the bowel, has been extruded through the anus. In these circumstances the practitioner has incised the mucous membrane and seized the tumour and detached it after ligaturing the pedicle. The patient recovered.[4]

Rupture of the cyst.—This is, I believe, the common way in which nature overcomes the difficulty, and if the cyst be thin-walled and the fluid sterile so far as micro-organisms are concerned the results are not necessarily harmful, but when the tumour has thick walls and contains dermoid material the effects are often very grave.

Brewer recorded a case in which an ovarian cyst obstructed delivery. The cyst burst and its contents escaped through a rent in the vagina; the woman recovered.[5] This observation is of some interest because some accoucheurs recommend in cases where a cyst obstructs the transit of the child that it should be emptied through a vaginal puncture (Herman). It is certain that some patients have survived this unsurgical procedure and that some have died after it. On one occasion a practitioner not only punctured the cyst but stitched the edges of the puncture to the vaginal wall.[6] Attempts to clear an obstruction of this kind by the vaginal route could easily be pushed a step further if the practitioner had a little operative experience and the whole cyst could be removed through an incision in the vagina, a procedure recommended by Dakin.

As delivery by nature's own efforts when a firm ovarian cyst or solid tumour blocks the pelvic outlet can scarcely be described as successful it will be useful to consider the various expedients adopted by accoucheurs to meet these difficulties and the results which have accrued therefrom.

A remarkable case is that reported by Berry. A woman taken in labour with her tenth child was found to have her pelvis obstructed by a tumour. The child was delivered by forceps. The same evening the patient felt something escape from the vagina during a fit of coughing. This Dr. Berry recognised as an ovarian cyst extruded through a rent in the vagina. He ligatured the pedicle and removed the tumour. The woman recovered. This cyst is preserved in the museum of St. Bartholomew's Hospital.[7]

In 1898 a ruptured ovarian dermoid was exhibited at the Obstetrical Society of London which had obstructed labour in a woman, 27 years of age, the mother of one child four years old. Attempts made to deliver with forceps failed; the dead child was then extracted by turning. Next day signs of peritonitis appeared and the patient died on the third day. At the post-mortem examination the burst dermoid was found.[8]

In a case full of interest recorded by Griffith delivery was obstructed by a large solid tumour of the ovary. He performed craniotomy, but then the fœtus could not come through; he then turned the child and even in this way its transit was difficult. The mother died.[9] This is a rare complication and it gave rise to an erroneous diagnosis. Griffith regarded the mass to be an extra-uterine fœtus. The pelvis, in section, is preserved in the museum of the Royal College of Surgeons of England and is represented in Fig. 1.

When a small dermoid obstructs delivery it may be possible to effect delivery by turning, but I think the subjoined case is not a recommendation for this manœuvre.

CASE 3.—A young married woman under my care in 1892 made the statement that she had been twice delivered of stillborn children after exceedingly difficult labours. The fœtuses in each case were extracted by turning and her life was despaired of after each confinement. On the second occasion the practitioner detected a tumour in the pelvis. I removed this in the Middlesex Hospital; it was an ovarian

dermoid with an average diameter of five centimetres firmly fixed to the pelvic floor by dense adhesions. The patient recovered and re-conceived and had a living child two years after the operation.[10]

The methods of dealing with labour when obstructed by a pelvic tumour which we have just considered may for

FIG. 1.

convenience of reference be described as craniotomy, forceps, and version, and they have only been mentioned and illustrated by typical cases in order that they may be thoroughly condemned.

To-day the choice of treatment really lies between two methods. 1. In the early stage to push the tumour out of the pelvis and allow labour to be completed and then at some convenient season to perform ovariotomy. This is often referred to as "reposition." 2. To perform ovariotomy at once and then to accelerate the labour by the use of forceps. If the tumour cannot be extracted then perform Cæsarean section. This method may be conveniently referred to as ovariotomy which may occasionally require Cæsarean section. The two cases which I detailed in opening this lecture illustrated very well some of the chief points of the two rival methods, but it is necessary to enter somewhat into detail concerning re-position because it is advocated by some obstetricians whose experience entitles their opinions to careful consideration. They advocate reposition whenever it is practicable on the ground that it allows labour to be completed, and although the necessity for ovariotomy is not avoided, nevertheless it does allow such an operation to be carried out in a more convenient manner and under conditions which not only safeguard it from sepsis but permit it to be performed by an individual skilled in this class of work.

To these views it may be urged that the surroundings of a woman in labour ought to be such that she runs no risk from sepsis. At the present time no surgeon would think of performing even a trivial operation without antiseptic precautions of some formula or other, and exactly the same precautions should be made for nature's interesting and important operation of childbirth. Further, in all large towns experienced operators are available and, in the case of the poor, well-equipped hospitals are always ready to receive urgent cases of this kind, as well as accidents, into the wards; and it is undeniable that an ovariotomy performed by an operator skilled in pelvic surgery is attended with far less risk to life and health than a normal labour in septic surroundings.

There are two very grave dangers which attend reposition—namely, rupture of the cyst and acute twisting of the pedicle; each of these are conditions which when they occur in non-pregnant women are held as justification for immediate ovariotomy. It is easy to collect half a score of cases in which reposition has been successful, but the unsuccessful cases are not recorded and thus we are deprived of any means of comparison. Be this as it may, I am quite certain from the remarks made at the Obstetrical Society of London in 1897, on the occasion when Dr. R. G. McKerron's painstaking paper on "The Obstruction of Labour by Ovarian Tumours in the Pelvis" was read, that the majority of practitioners will, when face to face with a difficulty of this character, make a determined effort to push the tumour out of the pelvis. This is, however, decidedly in opposition to all the canons of surgery, as I will now endeavour to show. It may perhaps be useful to indicate the position in a decided way and to state that *pregnancy exerts a baneful influence on ovarian tumours; and ovarian tumours are, as a rule, inimical to successful pregnancy.*

As a matter of fact tumours of the uterus as well as those arising in the ovaries are very liable to induce abortion and it is difficult to state which are the more pernicious in this respect, but I will take the opportunity of relating the details of a case which will well illustrate the malign influence of even a small ovarian tumour in pregnancy.

CASE 4.—A woman, 26 years of age, was placed under my care in the Middlesex Hospital in 1900 on account of a small ovarian tumour. The patient had been married 18 months, and in this short time had miscarried on three occasions and was pregnant for the fourth time. After the third abortion a small moveable tumour was detected at the back of the uterus, and when her medical attendant realised that she had again become gravid he urged her to submit to operation. I performed ovariotomy and removed the right ovary which was converted into a cyst as big as a fist, and the pregnancy, which had then advanced to the end of the second month, was not disturbed, and she is now daily expecting her travail.

In studying the literature of ovarian tumours complicating pregnancy, and especially tumours incarcerated by the gravid uterus, one of the most prominent facts is the frequency with which the tumours are dermoids; in many instances also the dermoids are bilateral, and this is a fact to bear in mind. For example, Berry Hart performed ovariotomy on a woman in the beginning of the fifth month of pregnancy and removed a dermoid of the left ovary "enlarged to about the size of a man's brain by recent hæmorrhage resulting from a twisted pedicle. The patient made good progress for a week, but on the ninth day died of cardiac failure." A frozen section was made of the pelvis, and on inspecting the cut surface the right ovary was seen to be incarcerated in the recess of the sacrum (Fig. 2). Bilateral ovarian dermoids co-existing with, or detected soon after, delivery have been observed and recorded by Knowsley Thornton, Bantock, F. Page, Cullingworth, and others, including myself, which have demonstrated that a woman may have one or both ovaries transformed into dermoids and yet they are capable of yielding fertilisable ova.

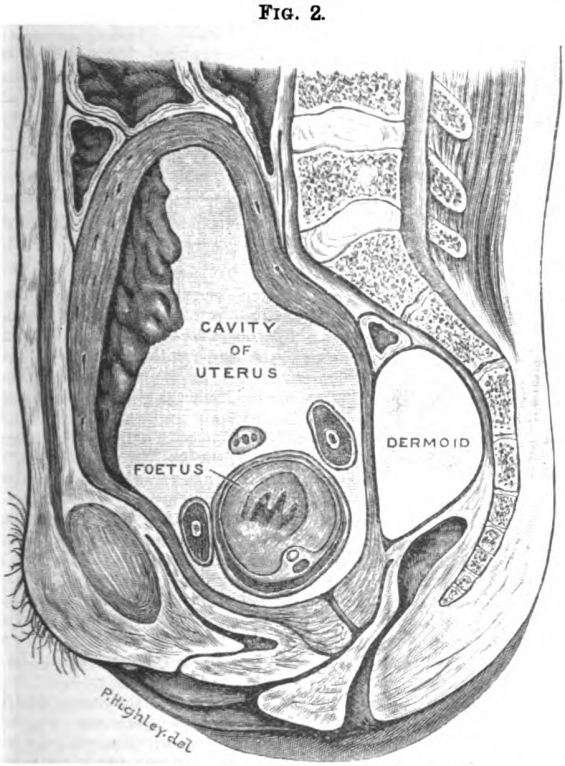
It may not be amiss if I briefly draw your attention to the steps by which the surgical treatment of ovarian tumours complicating pregnancy has been evolved. Although ovariotomy during pregnancy had been successfully performed in 1847 by Burd of Shrewsbury, by W. L. Atlee in 1850, and by Marion Sims, the procedure did not meet with favour until Spencer Wells forced it on the professon in 1877. This surgeon had pointed out its justifiability in 1870; but seven years later he strengthened his argument by reporting nine cases of ovariotomy during pregnancy with one death. The discussion which followed the reading of his paper at the Obstetrical Society of London is well worth perusal as indicating the opinions regarding this grave complication and its treatment held by the leading obstetricians of that period. A very large number of cases have since been recorded which show that it is now the recognised method of treatment in the early stages of pregnancy.

It would be suspected that the risks of ovariotomy during pregnancy would be those of an ordinary ovariotomy *plus*

[10] Medical Press and Circular, 1892, vol. ii., p. 94.

the chance of abortion with its ordinary dangers, but an analysis of a large number of cases demonstrates that when ovariotomy is performed before the fourth month of pregnancy the chances of abortion are very small, whereas the average mortality is less than in ovariotomy performed on non-gravid women. The risks of even double ovariotomy during pregnancy when the operation is undertaken before the fourth month are very small and the chances of disturbing the pregnancy are few. A critical study of a large number of records led me to formulate the results in this

FIG. 2.



Frozen sagittal section of a pelvis at the beginning of the fifth month of pregnancy. A dermoid of the right ovary is incarcerated in the hollow of the sacrum by the gravid uterus. (From Clarence Webster's Researches on the Anatomy of the Female Pelvis.)

way: Before the fourth month of pregnancy single and double ovariotomy is attended with an exceedingly low rate of mortality, and the risk of disturbing the pregnancy is small. The removal of a parovarian cyst during pregnancy is more liable to disturb the uterus than simple or double ovariotomy. After the fourth month the risk is that of an ordinary ovariotomy, but the chance of abortion increases with each month.

Now that we realise the importance of removing ovarian tumours whenever they are detected quite a large number of records have been published in which ovariotomy has been successfully performed in the later stages of pregnancy, and in three instances it has been carried out successfully at the end of the ninth month of pregnancy by Pippingsköld,[11] by myself,[12] and by Morse.[13] In Morse's, as in my patient, the tumour was a dermoid incarcerated in the pelvis by the pregnant uterus. In my case the tumour was detected during the birth of the patient's child, which was stillborn in consequence of the obstruction which it offered to delivery, and no active steps were taken to have the tumour removed until the woman was again well advanced in pregnancy (seven and a half months). This being the condition I thought it judicious to keep her under observation in the hospital until near term, so that in the event of the operation precipitating labour the child would be thoroughly viable. Five years after the operation the mother and child presented themselves in excellent health.

It has now been clearly demonstrated that ovariotomy has been performed with very marked success in each of the nine months of pregnancy and it has now in a fair number of instances been carried out whilst the patient was in labour. In this extreme condition the necessity for ovariotomy may be formulated thus: When an ovarian tumour is discovered during labour and it impedes delivery ovariotomy should be performed. If the tumour offer no obstacle to the passage of the fœtus it should not be interfered with until after the puerperium unless unfavourable symptoms arise.

It may be urged in reply to the above aphorism that it is not always easy to carry out the operation, and in the case with which this lecture opens it was impossible to extract the tumour from the pelvis until after the uterus had been emptied by Cæsarean section. This difficulty also occurred to Dr. Boxall; it is clearly one which will present itself from time to time. I have thought it desirable to add a list of recorded cases in which ovariotomy has been performed upon women actually in labour. The cases have been drawn from purely British sources. For this I hope not to be accused of what is sometimes facetiously called "insularity." I am convinced that the enormous population of this island should furnish material enough to settle the principles of treatment which should govern these terrible cases of obstructed labour.

Ovariotomy for Tumours obstructing Labour at Term.

Boxall *	Dermoid.	Recovery.	Ibid., vol. xl., p. 25.
Bland-Sutton *... ...	Dermoid.	Recovery.	This lecture, Case 1.

* In these cases Cæsarean section was necessary in order to extract the cyst from the pelvis.

It is not stating the case too positively to assert that "when an ovarian tumour complicates pregnancy the life of the woman is imperilled throughout the whole of the term; the peril increases with each succeeding month of gestation and culminates in a climax with labour (or abortion)." During delivery, however, mischief may be produced which is only appreciable during the puerperium.

Throughout this lecture we have almost exclusively considered those cases where an ovarian tumour is incarcerated in the pelvis and obstructs (as a rule completely) the transit of the child. We have now to deal with a much more insidious, and a far more fatal, complication—namely, where an ovarian tumour complicates labour and delivery is completed without in some cases its presence being even suspected. The two great dangers at this period are (1) rupture of the cyst and (2) axial rotation.

It is natural to infer that when an ovarian cyst with thin walls be subjected to pressure from a uterus during labour it would burst, and it by no means follows that the accident is necessarily lethal, for cases have been accurately observed in which the cyst has burst and the fluid absorbed by the peritoneum has been excreted by the kidneys. All operators of experience in abdominal surgery have found collapsed ovarian cysts in the abdomen and the intestines inundated with the viscid colloid stuff, and after removal of the tumour the patients have recovered. It is also true that even the distribution of the greasy material characteristic of dermoids among the pelvic viscera and adjacent sections of the intestine is not always attended with fatal consequences; an ovarian cyst may be ruptured during delivery and may cause such disturbance that the patient's life is jeopardised, or in many instances destroyed. In other cases the collapsed cyst may slowly refill and may require to be removed many months afterwards.

When pregnancy and labour are complicated with ovarian tumours the latter are very liable to undergo axial rotation and to twist their pedicles. It is quite true that almost every viscus in the abdomen is liable to axial rotation, yet all writers on the subject agree that this accident most commonly arises with ovarian tumours associated with a

[11] American Journal of Obstetrics, vol. xiii., p. 308.
[12] Brit. Med. Jour., 1895, vol. i., p. 461.
[13] Transactions of the Obstetrical Society of London, vol. xxxviii., p. 221.

pregnant uterus. I have studied the question very closely and carefully. The torsion may occur early in the pregnancy or it may be delayed till delivery. The occurrence of acute torsion at the time of delivery (or abortion) is due to the rapid diminution of the uterus and the movement which this organ as it sinks into the pelvis imparts to the tumour. A case of very great interest in relation to this question was reported by Dr. St. John Edwards in THE LANCET of 1861.[14] A woman, 24 years of age, had for at least two years previously an ovarian tumour on the right side which did not attract much attention until she became pregnant in 1860. In October of that year she was delivered of a child who only survived a few days. Immediately after the birth of the child the tumour shifted over to the middle of the abdomen. On August 5th, 1861, this woman was delivered of another child at the seventh month; the infant lived a few hours. After the child was born the tumour was found in the middle line of the abdomen. The patient died three days later. At the post-mortem examination the pedicle of the cyst was found twisted one and a half turns; it contained four litres of blood-stained fluid. The ovary was on the surface of the cyst, which was therefore parovarian in origin. I have often referred to this case, for it illustrates very well the fact that the majority of ovarian cysts, when they rotate axially, turn to the middle line and instead of occupying a lateral position lie in the hypogastrium. I have on nine occasions performed ovariotomy when the tumour has been noticed a few days after labour. The patients state that they notice that the abdomen does not return to its proper size and in some instances that it seems to enlarge again. This enlargement in some of the cases was due to bleeding into the cyst. A marked feature in all the cases, and one which led to some doubt in the diagnosis, was the way in which the tumour occupied the middle line of the abdomen and simulated an enlarged uterus and in all the cases axial rotation had occurred. In some of them the skin of the abdomen exhibited the peculiar yellow pigmentation so often associated with pregnancy, but which very rapidly disappeared after the removal of the tumour. The axial rotation of an ovarian cyst not only menaces the life of the patient immediately on its occurrence, but the longer it is allowed to persist it increases the difficulty, and therefore the risk, of ovariotomy by establishing extensive adhesions between the tumour and the adjacent viscera, especially the intestines.

Another danger which threatens a puerperal woman when she has an ovarian cyst is the liability of the cyst to suppurate. A critical study of a large collection of histories of patients who have had their "labour" complicated with ovarian cysts shows that in the majority of instances the cysts have twisted pedicles and that in a fair proportion of cases suppuration has occurred in the cyst. In many of the cases a ruptured cyst has been found.

It is now a well-attested fact that ovariotomy can be successfully performed even while labour is in progress—that the operation in no way interferes with the contraction of the uterus. Single and even double ovariotomy can be successfully performed in the puerperium without in any way interfering with either the involution of the uterus or lactation. Therefore, it cannot be too strongly urged that *when a puerperal woman known to possess an ovarian tumour exhibits unfavourable symptoms ovariotomy should be resorted to without delay.*

[14] THE LANCET, Oct. 5th, 1861, p. 336.

MORETONHAMPSTEAD HOSPITAL.—The hospital which the Hon. W. F. D. Smith, M.P., has endowed with £2000 and presented to Moretonhampstead, Devonshire, as a memorial to his late father, was opened on Jan. 26th. Owing to the death of the Queen the formal opening by Lady Esther Smith was abandoned.

NEWTON ABBOT BUILDING BY-LAWS.—At Newton Abbot (Devon), on Jan. 29th, a builder was charged with two breaches of the building by-laws of the Newton Abbot Rural Council—viz., that he varied the plans of cottages after they had been approved by the council and that he permitted the houses to be occupied without obtaining the usual "occupation certificate." The magistrates fined him £1 and costs in each case and also a penalty of 1*s.* a day until the by-laws are complied with.

A PLEA FOR THE MORE CAREFUL STUDY OF THE SYMPTOMS OF PERFORATION IN TYPHOID FEVER WITH A VIEW TO EARLY OPERATION.

BY WILLIAM OSLER, M.D. MCGILL, F.R.S.,
PROFESSOR OF MEDICINE, JOHNS HOPKINS UNIVERSITY, BALTIMORE, MARYLAND.

THIS plea is addressed to the resident physicians and the house physicians of the general fever hospitals, and to those practitioners who see a large number of cases of enteric fever. From 7 to 14 per cent. of typhoid fever patients die. During the first 10 years of my service at the Johns Hopkins Hospital there were 63 deaths among 829 patients—7·5 per cent., the minimum rate reached in general hospitals. Of the deaths in typhoid fever 50 per cent. are by asthenia—a result of the fever, or of the poison, or of both; 25 per cent. from perforation; from hæmorrhages and other accidents, 25 per cent. Modern methods—hydrotherapy and good nursing—have reduced the death-rate in the asthenic class. The perforation group, as shown by the statistics of the Brisbane General Hospital (Hare), of the Johns Hopkins Hospital, and of other institutions, remains much the same as given in the large statistics of Murchison and of Fitz. Whether with early removal of the patients to hospital there may be a still further reduction in the mortality of the asthenic or toxic group, we cannot say; but we can speak positively of a reduction in the death-rate in what has been the most hopeless of all the complications of the disease—perforation. I shall not take up space by any discussion of the conditions under which this accident occurs. I wish to call attention to the fact that *early diagnosis and early operation may save from 30 to 40 per cent. of the cases.* To Jan. 1st, 1900, there have been 11 cases operated on from my wards with five recoveries, 45·4 per cent. It is often a desperate remedy for a desperate condition. There are three groups of cases: first, those with so much infiltration and necrosis that the gut is not in a fit condition for operation, and the state of the patient may contra-indicate any attempt at resection. This was the condition in a recent case. In a second group the operation is successful, but the patient dies in the due course of the disease from the intensity of the fever or in a relapse. In a third group complete recovery takes place.[1] To incessant watchfulness on the part of my senior assistants and to their constant consultation with the surgical members of the staff I attribute the remarkable percentage of recoveries in our cases.

The classical picture of perforation in typhoid fever is in reality not of perforation but of the consecutive peritonitis, and the vital question is whether we cannot recognise the perforation and hand the patient over to the surgeon within 12 hours of the onset before the peritonitis has become widespread. Unfortunately the symptoms are often obscure, and I know of no more anxious and critical task than that which confronts us in some of these cases. What I am particularly anxious to urge is the careful study of the abdominal symptoms in every case of typhoid fever. Specific instructions should be given to the sister in charge of the ward to notify the house physician at once of any complaint of abdominal pain, of hiccough, of vomiting, of sudden rise in pulse or respiration, of unusual sweating, or of signs of collapse. The house physician should bear in mind that perforation is an accident liable to occur in the severe cases, in those with delirium, with diarrhœa, or with hæmorrhage, and in those with abdominal symptoms, so that he should be on the watch, and his daily notes should be made with a view of gauging the progress of the symptoms. The following schedule may help him in drawing up his clinical memoranda.

1. *The pain.*—(*a*) Its onset, whether simply an aggravation of the slight abdominal pain such as is common with constipation or with diarrhœa, or whether it is a sudden, intense pain, which causes the patient to call out, and which, though relieved by stupes and ordinary measures, recurs in paroxysms and grows worse. (*b*) Its locality, whether in

[1] It is interesting to note the increasing percentage of recoveries. In Dr. Finney's elaborate analysis of 112 cases in the literature the death-rate was only 21. (Johns Hopkins Hospital Reports, vol. viii.)

the hypogastric or in the right iliac regions, or in the region of the gall-bladder; whether it is diffuse or localised; whether it radiates towards the pubes or to the penis. It is to be borne in mind that abdominal pain of a severe character in typhoid fever may be associated with an acute pleurisy, with a distended bladder, with a packed rectum, or it may follow an enema, or it may occur with acute cholecystitis.

2. *The state of the abdomen.*—(*a*) Whether flat, scaphoid, or distended, and whether, if distended, it is uniform, or chiefly in the hypogastric region. (*b*) The respiratory movements, whether seen uniformly, and whether below and above the navel. It is to be borne in mind that perforation may be present with a flat or even with a scaphoid abdomen. (*c*) Palpation. Observe the degree of tension of the abdominal wall, the presence of pain on pressure, the locality of the pain, the extent, the degree of pressure necessary to elicit the pain, and whether it is a pain of increasing severity; the presence or absence of muscle rigidity or spasm, noting particularly its presence or absence in the hypogastric region and in the right iliac fossa. (*d*) Percussion. The character of the note in the front of the abdomen and in the flanks. Auscultatory percussion may be helpful when gas is free in the peritoneum. A flat note in the flanks may be present, due to exudate, within 20 hours of the occurrence of the perforation. (*e*) The liver flatness. Note specifically every third hour after the onset of the symptoms the extent in the middle, nipple, and mid-axillary lines. Remember that obliteration may occur in a flat as well as in a distended abdomen. Complete obliteration in the nipple line may be caused by excessive tympany, but rapid obliteration in a flat, or a not much distended, abdomen is a valuable sign. (*f*) Auscultation. Note the presence or absence of the signs of peristalsis. A friction may be early, within 12 hours of the onset. (*g*) Examination of the rectum—whether there is tenderness or any fulness between the rectum and the bladder. (*h*) The stools—the character, frequency, and the presence of blood or sloughs. (*i*) The urine—whether pain on micturition, frequency, &c. The onset of symptoms with pain about the bladder or in the penis is not infrequent when perforation takes place in the coils of the ileum in close contact with the bladder.

3. *General condition of the patient.*—(*a*) Facies—whether there has been a change in expression; the presence of a risus sardonicus, marked or slight; the onset of pallor or of sweating; and the signs of collapse, as in cold hands, cold feet, and slight dusky suffusion of the face. (*b*) The pulse—whether a sudden change in the rate and force; the very rapid, running, thready pulse may not be present for 24 hours after the onset of perforation. (*c*) The temperature—whether a sudden drop or a sudden rise. (*d*) Respiration—a sudden increase, which is not infrequent; whether shallow and sighing; (*e*) Hiccough—sometimes a symptom of onset, more frequently late, when peritonitis is established. (*f*) Vomiting—whether with the onset of the pain; it is more frequently a late feature, associated with the presence of the diffuse peritonitis.

4. *The blood count.*—The constant leukopenia in typhoid fever must be remembered. In a majority of instances in cases well followed there is a rise in the leucocytes, but this is not constant; they may be stationary. Also note the condition of the red blood corpuscles and the hæmoglobin. A decided drop may suggest hæmorrhage.

Sudden pain, increasing in intensity, and recurring in paroxysms, is perhaps the most constant symptom of perforation. With an increase of the pulse rate, distension of the abdomen, increasing pain on pressure, and a rise in the leucocytes, the diagnosis is rendered probable. A surgical colleague should be called early, so as to share the responsibility of the case. In a doubtful case the patient should be given the benefit of the doubt and operation should be urged. It is surprising how well a patient, even in a desperate state, may stand it. A general anæsthetic may not be needed. In many cases cocaine has been used, with the help, sometimes, of a whiff of chloroform. One of our cases recovered after three operations in two weeks, two for perforations and one in which a perforation was suspected.

From a surgical standpoint the whole question is reviewed at length by Keen in his "Surgical Complications of Typhoid Fever" and by Dr. Finney and Dr. Cushing in the recently issued Series III. of "Studies in Typhoid Fever," in Johns Hopkins Hospital Reports, vol. viii.

Medicine has become a medico-chirurgical art, and to practise successfully we physicians must know the work of the masters in surgery. In the diagnosis of disorders of the abdomen we are their pupils. In cases likely to become surgical the early association with a surgical colleague is both a duty and a pleasure.

Baltimore, U.S.A.

OBSERVATIONS BASED ON THE PROBABLE MODE OF FORMATION OF URINARY STONE, RELATIVE TO ITS RECURRENCE AND PREVENTION.

BY REGINALD HARRISON, F.R.C.S. ENG.,
SURGEON TO ST. PETER'S HOSPITAL.

IN an article which appeared in THE LANCET[1] entitled "A Further Contribution to the Surgery of Stone in the Bladder" I endeavoured to illustrate how progressive this work had been during the latter period of the past century and how intimately this was associated with the general adoption of the method of operating which Bigelow originated in 1878 and which has since been known by the name of "litholapaxy." I then purposely left for further consideration the only feature connected with this class of operations which seemed to require amendment or improvement. I refer to the liability to recurrence, which is admittedly larger after crushing as compared with other methods for removing stone from the bladder, though the mortality of the former is considerably less. In the paper referred to there were 101 cases of stone operated upon by litholapaxy alone, in addition to other methods. Of this number there were six deaths, whilst in 23 cases there was recurrence in some degree. The average age of these 23 persons was a fraction under 63 years. Several of the recurrences only amounted to the formation of some phosphatic gravel mixed with tenacious mucus, which was readily removed by the washbottle and aspirator. 17 of these persons had considerable enlargement of the prostate, 12 had pouched bladders, and the same number were more or less dependent upon their catheters at the time of operation. In two cases it seemed probable that recurrence was due to fresh descents of stones from the kidney and their retention within the bladder by the large prostate. In one of the fatal instances recurrence was traceable to a pouched bladder complicated with neglected urethral stricture and chronic suppurative nephritis. Hence it may be inferred that though a stone is successfully removed by operation this does not necessarily imply that the original cause for its production has thus coincidently ceased to exist.

From these statements it seems clear that the class of cases where the tendency to recurrence is greatest and most difficult to deal with, subsequently to the primary operation, is that in which, before stone formed, the bladder was more or less functionally and structurally spoilt by the obstruction it had been submitted to by enlargement of the prostate. It is hardly necessary to enumerate atony or loss of muscular power to expel urine, pouching, trabeculation, and cystitis, as being amongst these commoner effects.

The liabilities in its application to this class of cases seem in some degree to discredit the crushing operation in the eyes of the profession and public. Mr. Cadge in 1886 referred to it in the following terms: "This seems a heavy indictment to bring against lithotrity, but I am afraid there is no gainsaying it, and if so, it would be wrong to pass it over or make light of it. Many of these relapses might be prevented if the patients would observe directions and persevere with treatment."[2] I shall endeavour to show in detail, later, how we may succeed in giving effect to the latter statement.

On the other hand, in otherwise healthy persons without these prostatic and other defects the liability to recurrence of calculus in the bladder after operation is slight, as was also shown in the previous paper, and may usually be accounted for by the unexpected descent of a fresh nucleus from the kidney in the form of a small urate or oxalate

[1] THE LANCET, Nov. 12th, 1898, p. 1250.
[2] Hunterian Lectures, Royal College of Surgeons of England.

stone. This is a cause for recurrence which applies equally to lithotomy as well as to lithotrity, however performed.

The information we now mostly require relative to the removal of primary stone from the bladder under the conditions first mentioned of more or less permanent catheter-dependence and prostatic obstruction is not so much as to how quickly the operation can be effected, or how speedily convalescence follows, but as to what happens within the 12 months or thereabouts immediately succeeding it and concurrent with the abnormal states of the parts referred to.

The object of my paper is relative to the former class of cases, from which the greater proportion of stone recurrences after operation are drawn, and to show what has been done recently to diminish this tendency in them, and upon what principle or lines the latter may now be successfully attempted. Thus may we hope to lessen this liability and so to increase proportionately the efficiency of treatment. For it seems to be a more reasonable proposal to endeavour to extend the scope of an operation attended with so much to recommend it and so small a mortality than to substitute a more serious proceeding. Though lithotomy may be necessary for special reasons connected with the size or hardness of a stone or for other considerations, I can hardly see how its mortality, apart from other drawbacks, is likely to be diminished in the future, having regard to the advanced age and enfeebled powers of the persons upon whom it is usually practised. A repeated litholapaxy or a substituted lithotomy are in no sense comparable in elderly or feeble people. I purpose, therefore, to deal with the class of cases noticed as being most prone to recurrence. I will arrange my remarks under three headings: (1) the local treatment of the bladder following litholapaxy; (2) preventive treatment based upon the mode in which it is assumed that urinary calculi are formed; and (3) some illustrative cases.

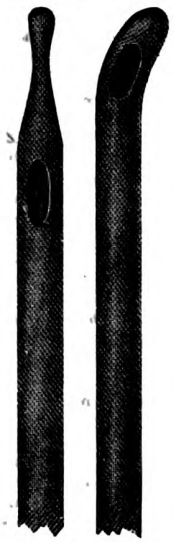
I.—THE LOCAL TREATMENT OF THE BLADDER FOLLOWING LITHOLAPAXY.

For some time past I have acted on the rule of regarding all cases operated upon for stone as "suspicious" until a sufficient interval has elapsed to free them from this imputation. This, as I have urged, is the more necessary in cases where the normal functions of the bladder are impaired by prostatic obstruction. Here personal supervision should be carried on for a period after the individuals have passed from the hands of the operating surgeon into those of the usual medical adviser. Such observation should have reference to the fact that there is a time in the history of all stones forming in the bladder, as well as in others where the nuclei descend from the kidneys in the shape of small calculi, when they would have escaped through an ordinary adult catheter as used for normal dimensions. Hence when the condition of the urine after an operation remains

FIG. 1.

abnormal, or unexpectedly becomes so, as indicated by appearance, smell, or microscopical examination, the bladder should be carefully attended to until such states are either explained or removed. Tentatively even under these circumstances, or for moving and withdrawing minute concretions or calculi, which would soon develop into larger stones, and before they have furnished full evidence of their presence, the bladder should be washed out as for exploration. Direct evidence of the necessity for this is often furnished by the withdrawal of a number of small phosphatic concretions or other crystalline bodies which on examination with a magnifying glass may be seen arranging themselves so as eventually to form distinct conglomerations of calculous material. In the accompanying illustration (Fig. 1), which is copied from Sir Everard Home's Lectures (vol. vi.), minute crystals of uric acid may be seen held together by wavy shreds of mucus in course of consolidation by the process described by Rainey, and which will be again referred to later, of molecular coalescence. These are frequently met with and may be readily recognised. If not removed they are the sure forerunners of stone. To effect their removal a suitable syringe and catheter are required. I have tried many kinds of the former and other apparatus used for washing out the bladder, but the best is a metal syringe made to fit various sizes of catheters. This should work easily, without jerking and with sufficient power for the purpose. The syringes I refer to are not liable to get out of order and can be readily rendered aseptic and kept so. The best catheters are the larger-sized, smooth-bored, silk web ones, with an ample bevelled eye (Fig. 2). The larger the instrument the better, so long as it will enter the bladder without causing pain or too much tension. It is convenient

FIG. 2.



to have the end somewhat funnel-shaped, so as readily and accurately to fit the conical nozzle of the syringe. For this purpose, until the patient is used to the passing of the catheter, the urethra may be rendered less sensitive by the application of a 5 per cent. solution of cocaine with a Guyon syringe. For injecting, warm water—preferably soft water—answers the purpose very well. If the urine is offensive boric acid, sanitas, or a solution of permanganate of potash may be added. Whatever is used should be used freely. From two to four pints at one séance, or even more, may be injected in instalments once or twice a day, the object being to dislodge any concretions that pouches or sacs may contain and to obtain a perfectly clear return fluid. Hence the object should be to sluice the bladder rather than to wash it in the ordinary acceptation of the term. I have often found it answer to fill the bladder fairly full and then to cause the patient to lie or roll on his stomach. By this and such like devices concretions may often be got rid of in considerable quantities. In some cases, when the bladder is sacculated and to make doubly sure, it is well to wash out occasionally with the usual evacuator catheter and aspirator as used for removing débris after litholapaxy, which will also be found a test or sound as to the presence of any calculous concretion that may be unable to escape through the eye of an ordinary flexible catheter. By attention such as is here indicated the bladder becomes gradually less liable to form these concretions, as I shall show when I refer later to some illustrative cases.

Where the mucous membrane remains relaxed and spongy, as evidenced by an excess of mucus in the urine, which is often met with in bladders that have held stones for considerable periods, it is well, after the usual sluicing has been finished, to conclude the process by injecting, two or three times a week, a couple of ounces of a solution of silver nitrate (one grain to 12 ounces). This may be increased in strength provided it causes no pain. It is the best astringent for this purpose, but its utility is often marred by being used too strong. This quantity of the solution should be left in the bladder after it has been emptied of the water or lotion previously used. By this means, as illustrated in the previous article,[3] the process of molecular coalescence may be interfered with. It is not possible to indicate precisely how long the local measures described must be continued or how often repeated. The absence or presence of the symptoms referred to in individual cases should determine these points. I will therefore pass on to the second portion of my subject, which may be utilised concurrently with what has been described.

II.—PREVENTIVE TREATMENT HAVING REGARD TO THE PROBABLE MODE IN WHICH URINARY CALCULI ARE FORMED.

It is stated, and no doubt with some truth, that the causation of stone is connected with processes of physiological chemistry as yet imperfectly understood. This may be so, but it must be a matter of common observation, considering the complex nature of stone-formation as it occurs in the human body, that advantage is not generally taken on more definite lines to abort the process and to render it inoperative. For it would seem that the more complex and precise are the conditions for a constructive act of this nature, the less likely is it to happen casually, whilst the more open is it to attack from the direction I have ventured to indicate. We may, for instance, be only imperfectly acquainted with all the changes connected with some delicate experiment, but none the less do we recognise how its failure may be effected.

It may be remembered that in 1851 Rainey [4] of St. Thomas's Hospital demonstrated a mode of making calculi artificially by what he described as molecular coalescence. The more recent works of the late Dr. Vandyke Carter [5] and Dr. W. M. Ord [6] tend to confirm and extend these views. It will not be necessary to refer to Rainey's experiments at length. From their study and repetition the following conclusions may be drawn in relation to the special object of this communication:—(1) that for the production of calculi artificially by molecular coalescence precision in regard to all details connected with it is required; (2) that success is dependent upon the sequence or concurrence of several factors or fixed conditions; and (3) that molecular coalescence as described by Rainey explains the formation of calculi in the human urinary apparatus.

1. Apart from any theory of stone-formation it could hardly be supposed that there are two or more ways of concreting the constituting elements of a calculus any more than there are two ways of forming a gumma, an atheroma, or other pathological product. This consideration probably largely underlies our modern views of therapeutics. The difficulty in procuring this precision in the conditions necessary for the formation of stone and their concurrence doubtless explains the comparative rarity of the disorder relative to the population as well as various apparent anomalies connected with its geographical distribution. The following passage from Rainey indicates what has to be provided for in the laboratory. Less exaction than this could hardly be expected in the bladder or within an organised body.

> The process of artificial stone-making consists in introducing into a two-ounce phial, about three inches in height, with a mouth about one inch and a quarter in width, half an ounce, by measure, of a solution of gum arabic saturated with carbonate of potash. The specific gravity of the compound solution should be 1·4088, when one ounce will weigh 672 grains. This solution must be perfectly clear; all the carbonate of lime which had been formed by the decomposition of the malate of lime contained in the gum and also all the triple phosphate set free by the alkali must have been allowed completely to subside.

If a fixed medium is required for the formation of stone, and precision in regard, for instance, to specific gravity, to such circumstances as chemical reaction, temperature, rest, and movement, and possibly to other physical, chemical, or bacteriological details, it must be obvious how comparatively rarely these conditions can casually concur in the human body and how open one or other may be to disturbance. Such elaboration necessarily opens a field for reflection in the minds of those who have to regard this combination of events from a pathological point of view.

2. I do not think that it is sufficiently recognised that in the multitude of factors or conditions necessary for the formation of stone there is both wisdom and safety. Illustration is given of this by the following consideration. Assuming that eight or 10 grains of so insoluble a deposit as uric acid is daily excreted it would appear that there is not an individual in fair health who is incapable of forming a stone in a reasonable time provided that the other circumstances for concretion are favourable. If, for instance, a man in the habit of excreting 10 grains of uric acid a day were only to void half this with his urine and concrete the remainder it is obvious that he might form a stone of this material alone, weighing not less than half an ounce, in something like 48 days.

It is hardly necessary to search for causes of excess in the excretion of uric acid when the natural amount, placed under favourable conditions, is capable of forming a stone of this weight in so short a time. If the production of stone were dependent upon a single link rather than upon a chain of them it is probable that these disorders would be far more common and general than they actually are. It would seem that hitherto we have almost exclusively paid attention to searching for causes of stone arising out of excesses of their characteristic ingredients rather than in studying other contributory conditions of the urine which are capable of bringing this about by the consolidation of that which is natural in the excretion. Extremes of uric acid, for instance, do not appear alone to influence the formation of this variety of stone. Its excess in the urine has not been shown to increase this liability in certain districts. The East Indian on his diet of milk and cheese, pulse, lentils, wheat, rice, and the like, as Mr. Freyer [7] pointed out, would appear not to suffer from excess of uric acid but from the power he possessed of converting all that a strictly non-nitrogenous diet can supply into stone.

The earliest stage of gravel and stone-formation as it may occur within the kidney or other portion of the urinary apparatus is well indicated in the following extract from a report on the urine of a person who from time to time suffered in this way: "A large number [of cells] yet remain unaccounted for, and these are believed to be derived from the superficial layer of the mucosa of the renal pelvis. Crystals of free uric acid are also present both singly and collected into microscopic masses. These facts taken together represent a conjunction of circumstances which, with the occurrence of hæmorrhage after exercise, seems to leave little room for doubt as to the correctness of diagnosis [calculus]." It is not unreasonable to suppose that the initial step of stone-making which is here demonstrated might without much difficulty be disturbed.

3. So far as the applicability of Rainey's views to the formation of human urinary calculi is concerned I will only quote the following passage from the late Dr. Vandyke Carter's work in support of it, as I am not aware that this has ever been denied.

> Regarding the probabilities of the case, it seems to me that the necessary conditions for the operation of molecular coalescence may at times well occur in the living human subject. Thus, an excess of mucus, perhaps altered in character, would furnish a colloid medium with which uric acid, the urates or oxalates, could combine in the manner described.[8]

On the assumption that Rainey's process explains the formation of stone as observed in man it would appear that molecular coalescence is capable of being disturbed or aborted by interference with the conditions indicated under the foregoing conclusions (1 and 2). This act differs essentially from what has already been attempted by dissolving stones after they have once formed. It is, however, not improbable that some remedies which have been in vogue for the latter purpose—for instance, those containing alkalies—owe their claims to this distinction by seeming to

prevent further formations on the grounds which I am advocating without in any material way diminishing the size of that which had concreted prior to their use. Preventing construction and effecting dissolution represent two different processes.

There are some interesting points bearing on this subject connected with drinking-water as used for ordinary purposes as well as medicinally. No one, I think, can doubt the efficacy of such spas as Contrexéville, Wildungen, Vichy, and others that might be mentioned, relative to calculous affections. During a stay which I made at the first-mentioned place two years ago I was much struck with what others have also noticed. In some instances the volume of water taken in conjunction with the exercise no doubt favoured the expulsion of small calculi by the mechanical act of flushing the part containing them. In others, though it did not appear to diminish the amount of uric acid voided, it seemed to prevent it collecting into small masses of crystals—that is to say, the latter showed a tendency under the influence of the waters to isolate rather than to aggregate. This was a matter of common observation with some of the habitués of the place. It seemed likely that in this way the process of stone-forming might be interfered with in its initial stage. Shortly before I had been struck with Mr. Cadge's[9] observations on the absence of milk as a food for children in the eastern counties of England relative to the prevalence of stone. I then made some observations on the effects of hard water used for drinking purposes under these circumstances, and though they were somewhat crude some results were obtained which appeared to be significant. Various samples of urine obtained from persons using such water were found to contain increased amounts of mucus, which were most marked in children. This test has since proved useful in assisting to determine the suitability of some hard waters for drinking purposes. Where the amount of mucus thus deposited is excessive it may be taken as tending to indicate that the water in question is not desirable, especially in the case of persons liable to gravel and urinary deposits. In connexion with this it is interesting to note that a change in the water-supply of a district—for instance, the substitution of some distant reservoir for local wells—has been found to alter substantially the liability of the inhabitants so supplied to stone and gravel.

These considerations suggest that an increased quantity of urinary mucus may provide a colloid for molecular coalescence and to this extent furnishes a necessary factor for concretion. Nor are such influences as I have mentioned confined to the use of certain waters, for they will be found similarly associated with various articles both of food and medicine. For instance, I have known persons who had been in the habit of passing small urate and oxalate calculi, attended with more or less pain and other symptoms, who apparently ceased to do so after taking from time to time short courses of such drugs as turpentine, sandal, copaiba, and others that might be mentioned—in fact, from the use of almost anything that has a distinctive and special action on the urinary excretion. I do not wish to be understood as expressing a belief that such drugs could dissolve a stone, whether small or large, when once formed or wherever situated, but in numerous instances their use appears to have been followed by a cessation of these discharges without necessarily interfering with the natural or excessive elimination of uric acid in this excretion. The presence of certain constituents of these drugs is judged as merely interfering in some way with the concretion of the latter into stone. Thus, as stated, may be explained the action of certain remedies, patented and otherwise, which have gained, properly or undeservedly, more or less notoriety in preventing the formation of stone and gravel. Some of these remedies which have come under my notice appeared to contain an ingredient which is admittedly capable of exercising some influence on the urine and may thus have been the means of disturbing a formative process in which this excretion was primarily implicated. Various alkaline salts formed the basis of some of them. A preparation called "Dutch drops" has for many years been a popular one.[10] It is stated to consist of "oil of turpentine, tincture of guaiacum, spirit of nitric ether, with oil of amber and cloves," the first ingredient being most likely the potent one in preventing crystalline concretion by molecular coalescence occurring as already suggested. Similarly the glycerine treatment[11] of renal concretions of uric acid may be explained.

An uncleanly condition of the urine, particularly of residual urine, where the individual is more or less dependent on the use of a catheter, is often a contributory cause of ammoniacal decomposition and the recurrence of stone after operation. I say a contributory cause of calculus, as some seem to doubt that a phosphatic stone can be formed without the presence of a nucleus upon which concretion can take place. Though this is frequently the case, it is not of universal application. Phosphatic calculi not rarely form in this way in the bladder, as in cases of advanced urethral stricture and sequential bladder changes, without any discoverable nuclei other than the concretion of the crystals of triple phosphate which the microscope readily discovers in abundance. The process of molecular coalescence is sufficient to explain this. Much may be done under these circumstances to prevent urinary decomposition by the use of the catheter and syringe as already referred to. Within the last few years improved means for sterilising the urine have also been largely and successfully employed. Effect is given to this on the same principle as milk, butter, and some food products liable to change under atmospheric and other influences are rendered more stable and less likely to undergo decomposition by containing certain proportions of boric acid or other innocuous antiseptics.

Some valuable drugs have been introduced for sterilising urine during its flow from the kidneys downwards and its storage in the bladder. Sandal wood, cubebs, and the like, doubtless owe some of their medicinal properties to their effects as bactericides, but they are nauseous and uncertain in their action. Some years ago I drew attention to an easily soluble and digestible salt of boric acid which often answers admirably and is much used by itself or in combination for this purpose. It is prescribed in teaspoonful doses in a tumbler of water, and may be taken frequently under the name of the borocitrate of magnesia. Many people use it with as much freedom as they do common salt with their food, as beyond sterilising the urine imperceptibly it appears to have no other action. Salicylate of sodium, benzoate of sodium, benzoate of ammonium, hyposulphite of sodium, are also useful sterilisers, which may be prescribed separately or in combination. Lastly, I would mention amongst this group a more recent introduction, under the name of urotropine, which is a valuable addition to it, and has in some instances a remarkable power of clearing urine and keeping it so. It is stated that its action is due to liberating formalin when mixed with the urine. By such means as these it is possible in some degree to wash out and to disinfect the pelvis of the kidney and the ureter, which in cases of chronic prostatic obstruction is often required, as much as, or even more than, the bladder. Thus a contributory cause of stone may be averted.

Of the effects of a solution of silver nitrate in preventing molecular coalescence and the formation of stone no more striking evidence can be afforded than those instances referred to in my previous paper.[12] In those cases by the injection of a weak solution of this salt foreign bodies introduced into the bladder were prevented from becoming coated with phosphates. This has been utilised in practice in connexion with accidents arising from catheters where delay in removing broken portions from the bladder was unavoidable.

III.—Illustrative Cases and Remarks.

I shall endeavour to illustrate some of the foregoing remarks by cases in which recurrence of stone in the bladder after operation was successfully treated, mainly by local attention and partly by instances where other influences were brought to bear upon formations and reformations not necessarily vesical in their nature nor requiring operation. Amongst the latter are included cases of renal gravel and stone, which may be said to form the largest proportion of urinary calculous affections. This will entail dealing with this aspect of the subject in two sections—viz.: (1) illustrations where the treatment was for the most part local; and (2) those where other influences were employed in aborting the stone-forming process.

1. Of the 23 cases of recurrence of stone referred to in my previous paper as having occurred after operation in elderly men, 12 patients are known to have had no further

[9] The Etiology of Stone in the Bladder, British Medical Association, Norwich, 1874.

[10] Pharmacologia, fifth edition, 1822, by Dr. J. A. Paris, F.R.S.

[12] THE LANCET, Nov. 12th, 1898, p. 1250.

symptoms of recurrence for periods extending over from two to seven years. These persons were for the most part treated by local measures alone, as described in the earlier part of this paper, and as far as can be ascertained they have ceased to concrete stone. It has not been possible to follow up all the remaining cases, and but little reliable information can be ascertained about them. I am disposed to think that several of the patients have had no further recurrence, otherwise I should have heard of it. A few are hospital patients who cannot be traced. However, the 12 out of the 23 who are known to have remained well is a fair proportion for basing these remarks upon.

CASE 1.—The patient was a man, aged 79 years, whom I saw in 1890. He had a remarkable family history of stone, his grandfather, father, paternal uncle, and himself all having suffered in this way. A large prostate rendered the operation not an easy one. He had five recurrences, which were all treated by litholapaxy. The last occasion was in June, 1893, after which the process of washing out the bladder daily as previously described was commenced. Afterwards I sent him to take the waters at Harrogate, where he remained under the care of Dr. G. Oliver. Writing to me some months after this course he stated: "The urine is clear, acid, and free from deposit, and I am able to go about without my catheter in my pocket, a thing I never did for years past." He died at the end of 1898, without further recurrence, at the age of 87 years, having led an active life to within a few months of his death. My belief is that the local treatment and the sulphur waters effected the twofold objects desired in the manner suggested. The original calculus crushed was a triple phosphate weighing 53 grains, and those that recurred were of the same nature. The later operations rarely detained the patient to the house for more than a few days. In this case the urine was so continually alkaline and ammoniacal that I finally tried the artificial induction of the lactic fermentation, apparently, as in other instances, with success in preventing the precipitation of the mixed phosphates. This was first suggested by the late Sir William Roberts,[13] the object being to bring about and maintain an acid reaction of the urine by overpowering the ammoniacal tendency until the bladder, so to speak, had time to return to a more normal condition.

CASE 2.—In this case a man, aged 60 years, was seen by me in 1890 with Mr. F. Grant. A phosphatic calculus weighing two drachms was removed by litholapaxy in March of that year. During that year and the subsequent year he suffered from several recurrences which required removal by the lithotrite and washbottle. This entailed his giving up an active professional life. In 1891 he commenced the systematic method of washing out described and has had no further return since. Writing to me in 1899 he says: "I still, however, go on with the washing out, as I should not feel safe without it, and it is no trouble." He has resumed his work as usual. As in the previous case, the patient told me that he had been frequently advised to submit to a lithotomy and bladder drainage. He remains quite well.

CASE 3.—In the following case, though no recurrence of the stone took place, it will be seen how this was probably averted. It was that of a man, aged 67 years, whom I saw in 1893 and from whom I removed a stone by litholapaxy weighing one drachm. There was some prostatic enlargement. By regularly washing out the bladder in the way described from time to time with a solution of boric acid, masses of shreddy mucus containing triple phosphate crystals were frequently removed. Under the use of silver nitrate solution these eventually disappeared. In 1898, in spite of attention of this kind, considerable difficulty was experienced by him in using his catheter by reason of further enlargement of the prostate, cystitis, and repeated attacks of epididymitis. Again his urine became largely charged with triple phosphates, and muco-crystal strings and concretion appeared imminent. In 1899 double vasectomy was performed. This permitted a more thorough irrigation of the bladder with the large-eyed catheter and syringe, and the urine speedily recovered its normal condition, and the patient was again able to resume an active outdoor life. In getting rid of the phosphates and the excess of mucus, in addition to the local means mentioned, the sterilisation of the urine for stated periods of a week or ten days, from time to time, greatly assisted in effecting this and securing an acid reaction of the urine. Thus the almost certain recurrence of stone was averted. The steriliser used consisted of urotropine and benzoate of ammonium, five grains of the former and 15 of the latter drug in an ounce of chloroform water, taken thrice daily after food.

It may be observed that where at the time of operation and subsequently, as the consequence of prostatic enlargement, patients are more or less dependent upon the catheter, the local treatment by washing out with suitable instruments for preventing re-formation of stone entails little or no additional inconvenience. Where prostatic complications of this kind do not exist, and there is no such dependence on artificial aid for withdrawing the urine, either at the time of, or subsequently to, the litholapaxy, the precautionary methods adopted are of the kind employed in the following case.

CASE 4.—A man, aged 64 years, was operated upon by litholapaxy in January, 1897, when an oxalate-phosphate stone was removed weighing nearly two drachms. He was under observation for 10 days. In October, 1899, nearly three years afterwards, I again saw him with symptoms of stone, when about the same quantity of urate calculus was removed by litholapaxy, the patient remaining under observation for seven days. It seemed probable, from the entirely different character of the débris removed, that the latter stone was formed on the nucleus of a fresh descent from the kidney. There was no distinct symptom of renal colic, though those of vesical stone had been in existence for the previous two or three months. In the past year he has been tested once a month with the large eyed catheter and syringe as described. For the next 12 months the test will only be applied every eight weeks, unless occasion arise to indicate its more frequent use. He takes, in addition to this, five minims of oil of turpentine every night for the first 10 days of each month, and some urotropine and benzoate of ammonium in a draught on the following morning. The latter expedient is with the view of aborting any tendency to stone-formation taking place in the kidneys, where the nucleus of the vesical stones that were crushed came from. His prostate is somewhat enlarged and would probably trap any fresh descent from the kidney in the shape of a small urate or an oxalate calculus. For these reasons the double precaution has been now taken for the past year, and he is, as far as it can be judged, free from stone. Having regard to the past it will be desirable to continue these precautions in a modified degree for a year or so longer. Otherwise he is entirely independent of the catheter.

The cases which serve as the basis for these remarks were for the most part seen and dealt with in connexion with a record embracing my operations for stone during 1890–97. Since the last-mentioned date the views and practices here expressed and illustrated have had fuller effect given to them than in the previous series. The results, so far as they have gone during the three years ending with 1900, have tended to support their expression, as recurrences after operation have been less frequent, whilst the after-treatment of litholapaxy has been placed upon a more satisfactory basis. I have waited until a sufficient time has elapsed to speak with some assurance on these points.

I admit that it is difficult, if not well-nigh impossible in some instances, to give full effect to the mechanical details which are here described. Failures, therefore, must still follow and be expected, and it is these, however rarely they occur, that will make us turn occasionally to the old controversy—Would not a lithotomy have been better in the first instance? Possibly it might have been, but yet there remains something to weigh even against this. Individuality on both sides must receive some consideration in doubtful cases. The broader lines which govern the selection of lithotomy or lithotrity are in the majority of instances sufficiently obvious and applicable.

2. Passing to the second group of cases, which, for the most part, include voidable calculi and gravel voluntarily expelled by the act of micturition, formed and recurring independently of operations, I will offer a few illustrations as to how it seems probable that their construction may be interfered with. Reference has already been made to what has been observed at Contrexéville and elsewhere as tending to support this view, as well as to some indications following the use of different kinds of drinking water which appear to be significant. This brings us more directly in touch with the administration of drugs for the purpose under consideration.

The formation and recurrence of stone and gravel, terms which are only used as broadly indicating extremes of

[13] A Case of Lactic Fermentation in the Bladder, with Suggestions for the Use of the Lactic Fermentation as a Counter-septic Agent in Cases of Ammoniacal Decomposition of the Urine, THE LANCET, Feb. 25th, 1893, p. 405.

concretion so far as size is concerned, are met with in (1) urines that are more or less foul or that show evidence of decomposition; and (2) urines that are apparently normal.

1. The signs of decomposition to which importance should be attached are twofold: (1) the presence in the urine of flocculent masses of mucus containing crystalline material which may be seen by the microscope or by the naked eye, or may even be recognisable by the touch; and (2) an abundance of triple phosphate crystals in the urine as determined by microscopical examination of the excretion These suffice to indicate a liability to the formation of vesical stone which should not be neglected, more particularly in the case of persons who have already suffered from calculus or have undergone operation for it.

Apart from the employment of local measures, which were considered in an earlier part of this paper, modern therapeutics have added to our resources some important medicines which have already been referred to as sterilisers. Some of these may even be used with advantage as articles of diet, of which the borocitrate of magnesia is an example. Many instances might be quoted illustrating their power of removing those signs of urinary deterioration to which allusion is here made. It is not necessary to refer at greater length to them as they have already been named. By their internal administration in numerous instances the urine may be prevented from undergoing that kind of decomposition which enables certain products of the latter, by molecular coalescence, to form phosphatic stones of considerable size in a short time. I will pass on to say a few illustrative words relative to the second condition.

2. Urines that are apparently sound though excreted by individuals who are liable to suffer, not infrequently or lightly, from attacks of renal colic and stone, and are also exposed to some risk arising from the detention and increment of the latter in the bladder. These are the calculi which are usually of renal origin, and are best open to attack in the earliest stage of their formation. My attention was called some years ago to some cases of this kind due to the descent of small calculi from the kidney downwards, when, after the paroxysm of pain was over, the patients were treated by various drugs which were supposed, with some reason, to be chiefly eliminated through this system.

CASE 5.—The first instance was that of a man who had been in the habit of passing uric acid calculi for several years before I knew him. Eight years ago I crushed and evacuated a small calculus for him which had failed to escape from his bladder. It was only a small stone and confined him in the house for three or four days. Prior to this he must have passed from time to time over 100 calculi of the same kind, though rather smaller, which I now have. I have seen him only once since, about four years ago, when he was in excellent health. With the exception of three or four somewhat similar calculi which were passed within a few weeks after the operation referred to eight years ago, he told me that he had seen no more. Further, he informed me that he attributed this not to any change in diet, but to his taking, on the advice of a friend, five minims of oil of turpentine night and morning for the first week of every month. When I saw him four years ago he told me that he had not changed his residence or his habits since the operation four years previously, but I think that he has done so since. I was struck at the time by this statement, but was disposed to regard it merely as a coincidence which could not be accepted without something more approaching a verification of the conclusion which the man had arrived at. However, I am disposed to think that there is something in it. If the conditions necessary for the formation of a stone in the kidney, or for that matter elsewhere, are fixed and unalterable, why should not the inference be correct? There is nothing irrational in the belief that this temporary addition to the man's diet, unpalatable as it might be to some, spoilt the process of stone-formation as another might favour it. Without pursuing this reasoning further I made use of the information thus given to me.

Trials have been made during the last three years with such drugs as sandal-wood oil, copaiba, cubebs, and turpentine, much on the same lines as those detailed in the case narrated. The cases in which these drugs were employed in this way were those of persons suffering from the passage of oxalate and urate concretions, commencing their use about the time when the paroxysms of pain connected with the expulsion of these bodies were over. Care was taken to regulate the doses so as not to interfere with the digestion of the patient. A course of a week or 10 days every month was the period usually advised. The results were very satisfactory in many of the cases, the use of the drug selected apparently resulting in the cessation of further formation of calculous concretions. Sandal oil and oil of turpentine were the drugs which were found best adapted for this purpose. The following case, which occurred about the time I commenced these investigations, interested me as showing the way in which calculi could be influenced artificially.

CASE 6.—The patient was an adult male upon whom I operated by litholapaxy three years ago. He had a phosphatic stone in the bladder of about the size of a small pigeon's egg, the result of damage done to the bladder by a chronic urethral stricture. He was operated upon at St. Peter's Hospital under gas and ether administered by Mr. W. Braine. On washing the fragments of stone out of the bladder after crushing it was noticed that they were all of a deep blue colour. I was at a loss to explain this at the moment, and so were others who were present in the operating theatre. It turned out on further inquiry that for three weeks previously the patient had been taking for his bladder symptoms a medicine containing methylene blue. He made a good recovery.[14]

In an interesting paper relating to stone formation Dr. Lindley Scott[15] has recently shown how oxalate of lime may be artificially resolved into other combinations and so be excluded in this form from the urine. Thus the formation of this kind of stone may be rendered inoperative.

It is hardly necessary to say in connexion with the tendency to the formation of urinary gravel and stone that morbid conditions of the excretion as indicated by an excess of normal constituents, or by the introduction of elements which are foreign to the urine, should as far as possible be dealt with on general principles which are sufficiently recognised and provided for. Excesses of urates and uric acid, for instance, as observed in the gouty, and the introduction into the urine of oxalates, cystin, and the like, are indications which will not be allowed to pass without special notice and attention. My contentions, however, are for the most part based upon proportions which may be normal.

I will briefly refer to two points connected with the processes of removing stone from the bladder which have a bearing upon the subject of recurrence.

In the first place every care should be taken, especially in the case of crushing operations, to remove all fragments of stone from the bladder. It should be remembered that the bladder of a man obstructed by an enlarged prostate in front of it, not uncommonly more closely resembles the section of a coarse bath sponge than the inside of a tea-cup. Thus the difficulties of clearing the former are considerably increased as compared with the latter. But the successful accomplishment of this is not often unattainable and should be first demonstrated to be so before crushing is put aside on this ground.

In the second place, care should be exercised, whether lithotomy or lithotrity is selected, to avoid introducing rough scar-tissue into the bladder. It is just as liable to cause stone concretion as any other foreign body. I illustrated this in the Surgical Section at the meeting of the British Medical Association in 1900. One reason for the success and comparative rarity of stone recurrence noted in earlier days by lithotomists who practised median and lateral lithotomy

[14] It would be interesting to know, particularly in regard to further developments, if any observations have been made as to whether the colour of a urinary calculus, apart from the nature of its chemical composition, exercised an influence on the shadow cast by the x rays. For instance, if a black oxalate stone gave a more pronounced outline than a similar one of a lighter colour, such information would be of value. It occurred to me that if depth of colour intensified the shadow thus produced it was possible to bring this about artificially. In the case I have recorded I found that a white phosphatic stone was deeply stained blue by the patient having previously been treated by a course of methylene blue (tetramethylthionine chloride) for cystitis. I have seen other vesical calculi stained a deep indigo colour in this way. I have wondered whether different degrees of intensity observed in radiographs of oxalate of lime calculi in the kidney were explainable on this principle. If so, a practical point in aiding their diagnosis in this way is suggested. I venture to raise this question, as feeling the great importance of endeavouring to discover calculi in bladders distorted by enlarged prostates without the use of a sound, and for calculi in the urine passages which are inaccessible to the touch. A stone in the bladder when detected by the sound under these circumstances should be at the same time removed. This is not always convenient. A stone detected by radiography permits of a delay without detriment, or reflection upon the process employed.

[15] Brit. Med. Jour., Oct. 13th, 1900.

correctly was that they introduced no scar-tissue afterwards within the area of the bladder. When I was engaged in teaching pathology and surgery I had several opportunities of demonstrating what would seem to support this statement. I have more than once scraped off phosphatic concretions from the rough uneven inner scar of a suprapubic cystotomy.

In preparing this paper, the subject suggested itself from a critical examination of my own work, which was not unconfirmed by that of others who also possessed ample means of obtaining information. It appeared to me that the liability to recurrence after lithotrity, or litholapaxy as it is now called, was larger than it should be and might be reduced. And further, that the whole subject of stone-formation and recurrence, relative to prevention and treatment, was capable of being reconsidered and dealt with on more precise and definite lines. This, I think, will be admitted to be the case, and that in attempting to do so we may fairly hope where surgical interference proves necessary to extend the limits of the crushing operation rather than to curtail them.

Lower Berkeley-street, W.

ON A CASE OF MYASTHENIA GRAVIS, PSEUDO-PARALYTICA; DEATH; NECROPSY; REMARKS.

BY LEONARD G. GUTHRIE, M.D. OXON., F.R.C.P. LOND.,
PHYSICIAN TO THE HOSPITAL FOR EPILEPSY AND PARALYSIS, REGENT'S PARK, AND TO THE CHILDREN'S HOSPITAL, PADDINGTON GREEN.

UNTIL Dr. Buzzard published his important clinical lecture on this curious and formidable disease[1] it was probably hardly known by name in this country. More recently, in the Summer Number of *Brain* for 1900, Dr. Harry Campbell and Dr. Edwin Bramwell have supplied a critical digest of the 60 or 70 cases hitherto recorded. Of these 11 only have been described by English observers, mostly under different synonyms. Yet the complaint may be less rare in England than it would seem to be. Dr. Buzzard mentions his impression that in addition to the four cases which form the subject of his lecture he has "seen with his eyes though failed to recognise the significance of not a few other examples of the disease." A similar impression may be shared by some of his readers with regard to their own experience. Most diseases have gone through a phase in which they are known though nameless. They are not recognised as entities until a comprehensive title has been invented for them, and this has been the case with myasthenia gravis. For a full bibliography of the subject reference may be made to the excellent monograph by Dr. Campbell and Dr. Bramwell. The typical symptoms and course of the disease are well illustrated in the following case (shown before the Clinical Society of London, February, 1900).

The patient a woman, aged 23 years, single, a waitress, was admitted to the Hospital for Epilepsy and Paralysis, Regent's Park, on Jan. 26th, 1900. She complained of general weakness, but in particular of difficulty of speech and deglutition. Her family history was said to be good. A paternal aunt was epileptic. (A sister shortly after this patient's death had a bad attack of chorea gravidarum from which she recovered.) As to her personal history she was always considered healthy until the present illness. She had been a waitress at various restaurants for the last four or five years and had been accustomed to work as many as 12 hours daily. With regard to her present illness, in December, 1899, she complained of always feeling tired, and towards the end of the day she found that she could not speak distinctly owing to spasm or (?) loss of control over her lower jaw. She used to make light of it, saying, "My jaw is refusing duty." Perhaps this symptom was akin to the jaw clonus noted in Buzzard's first case. In July, 1899, the difficulty of speech increased and was more frequent, and deglutition was also affected. She sometimes choked whilst trying to swallow solids and liquids returned through her nose. She also noticed that she could not fully close her eyes. Her trouble in articulation and deglutition gradually became more serious and also the general sense of fatigue. The fingers of the right hand often "dropped" so that she could not write or sew. All the symptoms were worse after exertion or if "put out" or "upset" in any way. There was no history of sore-throat. She remained at work until Jan. 16th, 1900, when she first attended hospital. Her condition then was somewhat alarming. She could hardly walk without assistance and her speech was quite unintelligible; her mother had to interpret all she said. When she tried to swallow water it came back at once through the nose. She could not shut her eyes. She was sent home with instructions to remain in bed until she could be admitted to hospital. On admission a week later her condition was considerably improved.

On admission she was found to be a slightly-built, delicate-looking girl, pale but not markedly anæmic. She had paresis of the orbicularis oculi and oris, of the tongue, soft palate, and probably of the pharynx. She could frown and elevate her eyebrows, but could not fully close her eyes. In the attempt to do so the eyeballs were turned up, exposing about half an inch of conjunctiva in the right eye and somewhat less in the left. She could offer no resistance to passive elevation of the upper eyelids. There was no ptosis. Even after prolonged up-looking the eyes remained fully open. Ocular movements were perfect; there was no nystagmus. The pupils were equal; their reaction was normal. The optic discs showed some pallor of the nasal half. There was no restriction of fields of vision. The mouth was weak-looking, half open, and the labial fissure was widened. At times the upper lip was elevated and the naso-labial fold was accentuated, giving her a disagreeable and scornful expression. But her aspect generally was melancholy, although she was not really so. She could not purse her lips up or blow out a candle unless she first held her nose. She could not whistle; but a year before, she said, she could do so "like a boy." She could not blow up her cheeks at all unless the anterior nares were first closed, and even then air readily escaped through the mouth owing to weakness of the orbicularis oris. The other muscles of expression were not paretic. There were no tremors and no wasting of the face. The tongue was protruded straight and was not obviously wasted. It was slightly tremulous after prolonged protrusion, but the tremors were not fibrillary. She could execute all other movements with it but could not curl it longitudinally. The associated action between the orbicularis oris and transverse lingual muscle was lost. The soft palate hung level and moved on phonation and respiration, but not to a normal extent. After speaking or reading aloud for a time the palatal movement was lessened. Speech was weak, indistinct, and markedly nasal. After talking or reading aloud for a couple of minutes she was almost unintelligible. The speech resembled that of persons with a cleft palate; air was heard to escape through the nostrils with each word. It was rendered still more indistinct by the difficulty in sounding labial explosives *b*, *p*, and the gutturals *k*, *g*. The vocal cords acted normally. No signs of fatigue after phonation were detected. Cough was forcible. Deglutition was rendered difficult by loss of prehensile power in the lips. She could not suck a spoon clean. Food tended to collect on the right side of the cheek, but not on the left, where she had lost her lower teeth. She had also difficulty in controlling the movements of a bolus of food with her tongue; she swallowed it slowly and with obvious effort, whilst liquids, as mentioned before, were often regurgitated through the nose. There was no apparent weakness of the masseters or pterygoids or elevators of hyoids. The dysphagia and dysphonia varied greatly. On first waking she could talk and eat fairly well; but towards the end of the day, or if tired, her difficulties increased. With regard to muscular power, the hand grasp (recorded by dynamometer) was as follows:—R. = 30; L. = 40. There was the same result after four trials. She could resist passive movements of the elbow, wrist, and shoulder and of the ankle, knee, and hip with a fair amount of force; but after a short time her resistance became intermittent. Actual loss of muscular power was not apparent except after exertion. After a night's rest she sat down, rose, turned, walked, and moved generally without obvious effort. None of the muscles were atrophied. As to the reflexes, the soft palate and pharynx moved on stimulation, but the reflex actions were perhaps diminished as she was very tolerant of laryngoscopic examination. Tendon and superficial reflexes were normal. The knee-jerks were not lessened after repeatedly tapping the

[1] Brit. Med. Jour., March 3rd, 1900.

patellar tendon. There were no tremors nor ataxy. The muscular sense was accurate. Sensation was everywhere normal. The thoracic and abdominal organs seemed healthy. Nothing abnormal was noticed in the pulse and respiration. She did not complain of breathlessness after exertion, but only of feeling generally tired. The sphincters acted normally. The bowels and menstruation were regular. The urine contained neither albumin nor sugar and was normal in quantity and appearance. Its toxicity had not been tested. With regard to electrical reactions, there was slight diminution to faradaism. There was no reaction of degeneration. As to myasthenic reactions, the right biceps was exhausted and ceased to react to faradaism in about one minute, contact being broken from 60 to 75 times per minute. The left biceps was exhausted in about one and a half minutes. Response to the current however, was restored in from 15 to 20 seconds if the application were stopped as soon as exhaustion occurred. If continued after exhaustion the period of inaction was increased. In the face the orbicularis oculi and oris were exhausted much more easily than the other facial muscles. The myasthenic reaction was far less readily produced in the muscles of the lower extremities than elsewhere.

Progress.—At the end of three months' observation the general condition had greatly improved. There was now no actual inability to swallow nor regurgitation. Speech only became indistinct after reading aloud for several minutes. The right eye could be almost closed, and resistance to passive elevation of the eyelids was more apparent than it had been. The mouth looked smaller and less flabby. She felt stronger and had gained three and a half pounds in weight. Treatment had been by rest and the administration of liquor strychniæ.

Subsequent history.—She left the hospital at the beginning of May, 1900, and went to Tunbridge Wells, where she remained until a severe relapse occurred on June 15th. Her mother believed that the relapse was due to mental trouble. An engagement to marry had been broken off and her *fiancé* had gone to the war in South Africa. When seen on June 19th her condition was much worse than it had ever been. She could not swallow water even in sips. Her speech was quite unintelligible and the palatal movements were more sluggish than before. Her mouth was full of glairy mucus and saliva which she could neither swallow nor eject. Her neck muscles were weakened, so that her head fell backward if she inclined it beyond the centre of gravity, unless she supported it with her hands. She was very depressed and tearful. On July 3rd the weakness of the neck muscles had passed off. On the previous day she had choked whilst trying to swallow a small piece of bread-and-butter. She could neither get it up nor down, but her mother succeeded in dislodging it with her finger. On the whole she seemed rather better. She was not seen alive at hospital again, but Dr. Edmund Holland of Regent's Park has kindly given particulars of the conclusion of the case.

On July 10th she started for a short walk, but soon returned, complained of great fatigue, and finally took to her bed. On the night of the 11th Dr. Holland was called to see her and found her suffering from a bad attack of dyspnœa. She was fighting hard for breath and he thought that she was dying. The attack, however, passed off in about an hour, after which she slept quietly. The next morning she was breathing easily, but she could not sit up in bed without assistance. She had only taken about a pint of liquid nourishment in 24 hours for several days, and deglutition was getting more and more difficult, so he ordered her to be fed by nutrient enemata only. On July 14th general weakness was much more marked. After talking a little her voice became reduced to a whisper. On the 15th the diaphragm was apparently paralysed, as she could not cough to clear her throat of mucus without pressing her hands on the lower ribs and epigastrium. She died quietly about 3 A.M. on the 16th. Consciousness was maintained until an hour before death, which was probably due to respiratory failure and gradual exhaustion.

Necropsy.—A post-mortem examination was made 30 hours after death. The body was slight in build but not emaciated. Rigor mortis was well marked. All the internal organs seemed healthy and also the brain and spinal cord.

Microscopical examination.—Dr. H. Campbell Thomson reports as follows: "The cord, medulla, and portions of cortex were hardened in formalin (5 per cent.), cut with a freezing microtome, and stained with carbol-thionin. The cells of the hypoglossal and glosso-pharyngeal nuclei for the most part appeared normal; in some, the chromatophile granules were not differentiated, and formed a homogeneous staining which, however, was not darker than normal. There was no loss of chromatophile bodies noticed in any of the cells. Cells from the spinal cord at the level of the third cervical roots showed similar changes. No other changes were detected either in the cells or in the other tissues of the cord. Examination of the cortex and of the nerve trunks gave negative results." Dr. Thomson considers the changes described as merely due to slight variations in staining and that the results of examination as a whole are negative. Thus the most modern methods of investigation only confirm the accuracy of Sir Samuel Wilks's description of the first case on record in this country, as one of "bulbar paralysis without anatomical changes."[2]

The motor-nerve endings in muscles were not examined in this case because portions of muscles removed for that purpose were unfortunately lost. Yet I venture to think that examination of them would probably have been also negative, for the variation in symptoms shows that the motor end plates or terminals in muscles, the most delicate portions of the neurons, cannot be permanently disorganised. This is implied by the descriptive term "pseudo-paralytica," which forms the sub-title of the disease. Myasthenia gravis is, in fact, a condition of toxæmia. The toxin, whatever it be, appears to have a selective and narcotic action on the motor neurons as a whole, and when the neurons attacked are vital, death is the result, in accordance with the virulence and intensity of the poison at work. Of the nature and origin of the toxin causing myasthenia, little or nothing is known. It is probably endogenous rather than exogenous, because the disease does not occur in epidemics or attack members of the same family simultaneously. It cannot be traced to any definite antecedent complaint. The supposed exciting causes have been so many and so various, yet so often altogether absent, that we cannot attribute to them any important part in the causation of the disease beyond that of weakening the patient and rendering him susceptible.

Origin of toxin in muscles.—The fatigue phenomenon suggests that the muscles are rendered inert by the products of their own activity. But Dr. Bramwell showed that this is not so by an ingenious experiment. He found that massage of an exhausted muscle (biceps) did not diminish the period of rest required before it resumed activity. Had the poison been muscle-bred, massage would have dispersed it. The absence of digestive disturbance is against a gastro-intestinal origin. Examination of the urine for poisons having a curara-like action gave a negative result in one of Buzzard's cases.

Origin in ductless glands.—The extreme muscular prostration which attends Addison's disease has suggested that the suprarenal bodies may also be affected in myasthenia gravis. The uselessness of suprarenal extract as a remedy does not disprove that this may be the case. The extract is probably a complex body and the active principle required may not yet have been isolated.

Possible splenic origin.—Dr. Sidney Martin[3] showed that the spleen is the chief repository of the poison of diphtheritic paralysis and that it is from the proteids of the spleen that the specific poisonous products are mainly formed. In Landry's disease the spleen is most commonly found enlarged and there is a strong resemblance between the symptoms of Landry's disease and diphtheritic paralysis and those of myasthenia gravis. Possibly, therefore, the spleen plays an important rôle in all these affections and is the chief factory whence the poisons are delivered into the circulation. But such theories are at present purely conjectural.

Diagnosis.—The diagnosis of so typical a case as the above presents no difficulty. The clinical details of myasthenia gravis are:—1. Bulbar paralysis, usually slight but at times extreme, affecting the lips, tongue, soft palate, pharynx, and larynx. 2. Weakness of the upper facial muscles, especially of the extrinsic ocular group, causing ptosis, ophthalmoplegia, or inability to close the eyes. The mid-facial muscles—e.g., zygomatic—seem commonly to escape. Of the vital bulbar centres the respiratory is more frequently affected than the cardiac. In a few cases palpitation and syncopal attacks have been observed

[2] Guy's Hospital Reports, 1877.

[3] Goulstonian Lectures, THE LANCET, March 26th (p. 677) and April 2nd (p. 735) and 9th (p. 787), 1892.

apart from, or associated with, dyspnœa. Severe or fatal attacks of dyspnœa may be due to falling back of the tongue, to abductor paralysis of the vocal cords, to paralysis of the intercostals or diaphragm, or to actual obstruction from food passing into the larynx or becoming impacted in the pharynx. 3. Weakness and readily induced fatigue of skeletal and trunk muscles. 4. Presence of so-called myasthenic reaction (the reaction of muscles to faradaism normal at first, but speedily exhausted). 5. Absence of muscular wasting and of fibrillary tremor, with a few doubtful exceptions. 6. Absence of sensory affection, of mental disturbance, and of incompetence of sphincters. 7. The deep tendon reflexes are usually normal, but rarely exaggerated; in a few cases they have been exhausted by repetition. 8. Remissions and exacerbations of the symptoms, both bulbar and general, are characteristic features. The pareses may disappear entirely after rest, but return on exertion. The ocular pareses alone are apt to be persistent. Strümpell supposes this to be due to the ocular muscles being in a constant state of activity. Perhaps the ocular muscles are more permanently disabled because their neurons are few in number compared with those of other muscles, and therefore fail more readily. The same muscles are apt to fail, without apparent affection of others, in syphilis, in early general paralysis of the insane, and in incipient tabes.

The mode of onset is usually gradual, rarely it is sudden, and accompanied by slight headache, pains in the neck and back, giddiness, and photophobia. In some cases the limbs are first affected, but ocular or bulbar symptoms commonly lead the way. The onset may be dated from some preceding illness in a certain number of cases, but not in all. There appear to be no limits as to the age at which the disease may occur. The oldest patient in Campbell and Bramwell's collection was 55 years of age, the youngest was two and a half years. The average age for men was 35 years and for women 24 years. Both sexes are about equally liable to the affection.

Prognosis.—Of 60 cases, several of which, however, are doubtful and many incomplete, 24 have proved fatal; two more fatal cases have been recorded by Hall[4] and Paul.[5] The average duration of the disease in fatal cases was one and a half years. In one it lasted 14 days and in another 15 years. Complete recovery is possible. One patient was in good health four years after all symptoms had disappeared. Goldflam regarded the disease as "a curable form of bulbar paralysis." But the method of cure is still to seek.

Differential diagnosis.—The symptoms of hysteria only superficially resemble those of myasthenia gravis. Weakness, lassitude, and readily induced fatigue are common enough in hysteria and neurasthenia, but the presence of the myasthenic reaction in myasthenia gravis (exhaustibility of reaction to faradaism) affords a distinction. In myasthenia gravis, moreover, sensation is almost invariably unaffected. As regards the ocular symptoms, hysterical ptosis due to spasm of the orbicularis should not be mistaken for myasthenic ptosis due to paresis of the levator palpebræ. True nystagmus does not occur in hysteria, nor do true ophthalmoplegia and inability to close the eyes, all of which symptoms are common in myasthenia gravis. The dysphagia of hysteria is characterised by prodigious though unavailing attempts to swallow. There are incoördination and over-action of the muscles of deglutition, and the effort fails at the critical moment, so that the bolus of food is regurgitated back into the month. As Dr. StClair Thomson expresses it, "The patient complains that 'she cannot get the food out of her mouth,' or that 'it goes down but comes up before it is half swallowed,' or that 'when she goes to swallow, a ball rises in her throat to meet it.'"[6] In hysteria liquids are usually swallowed with ease. The difficulty is with both solids and semi-solids. In myasthenia gravis there is no overaction or incoördination, but obvious weakness of all or most of the muscles concerned in deglutition. The soft palate is particularly apt to suffer, so that fluids slowly trickle through the nose as well as from the weakly closed mouth when an attempt is made to swallow them. Semi-solids are more easily assimilated than either liquids or solids. In both hysteria and myasthenia gravis liquids or solids may go "the wrong way." But in hysteria the attempt to dislodge them is forcible and the cough is explosive; fluids may be violently expelled through the nares, but this is not due to weakness of the soft palate as in the case of myasthenia gravis. In myasthenia gravis one is at once struck by the weakness of the cough and the ineffectiveness of the struggles to obtain relief, when this distressing and dangerous accident occurs. Hysterical dysphagia is pure'y histrionic.

The speech defects which occur in both hysteria and myasthenia gravis are not alike in character. Hysterical aphonia in which the voice is reduced to a whisper but articulation remains perfect, and hysterical mutism in which the patient looks at one with tear-laden eyes and makes pathetic *moues* or inarticulate sounds cannot easily be confounded with the dysphasia of myasthenia gravis. In the latter disease the voice may become inaudible owing to paresis of the adductor vocal cords and of other respiratory muscles, but weakness of the lips and tongue renders articulation also imperfect or even unintelligible. In hysteria speech may be indistinct from stammering and stuttering due to spasm and incoördination of the tongue and other muscles concerned, but in myasthenia gravis stammering and stuttering are absent. The voice in myasthenia gravis has, moreover, a marked nasal twang which is never met with in hysteria, for in that disease paralysis of the soft palate does not occur.

Hysterical dyspnœa has also to be distinguished from myasthenic. In hysterical dyspnœa respiration is usually quick, shallow, and forcible. There may be incoördination between the action of the intercostals and diaphragm, or sometimes over action or perverted action of the diaphragm and abdominal muscles. This condition may be taken for paralysis of the diaphragm unless the movements are timed, when it will be found that the deep epigastric recession is synchronous with expiration and not with inspiration. Continuous churning and bubbling sounds produced in the stomach, and at short intervals loud trumpeting noises suggestive of a cough, a hiccough, and an eructation combined in one, are associated with hysterical diaphragmatic dyspnœa. Cyanosis is absent and there is no real distress. The dyspnœa ceases during sleep and for the time if the patient's attention can be distracted from her woes.

In myasthenic dyspnœa the distress and the patient's futile efforts to relieve it are only too plain. Sudden attacks of dyspnœa in which the patient falls to the ground and is in imminent danger of asphyxiation are ascribed by Strümpell to falling back of the tongue, for he found that they were relieved by traction on that organ. Another explanation of the relief thus afforded may be that traction on the tongue excited the respiratory centre in the manner described by Lister in cases of chloroform asphyxia. Abductor paralysis of the vocal cords associated with respiratory stridor is also one cause of myasthenic dyspnœa. This is said also to occur in hysteria, but the event must be so rare as to suggest a doubt as to the diagnosis. Myasthenic dyspnœa may depend on paralysis of the intercostals or of the diaphragm and abdominal muscles. The motionless chest in the one case and the epigastric recession occurring with inspiration in the other are in striking contrast with the signs of over-action and perverted action of the intercostals and diaphragm noticed in hysterical dyspnœa. The coarse bubbling râles due to accumulation of mucus in the throat and air passages and the weak, hoarse cough in myasthenia gravis can hardly be mistaken for the gastric borborygmi and churning noises and for the weird admixture of sounds produced per os by hysterical subjects.

Finally, in making a diagnosis between hysteria and myasthenia one is helped by the presence or absence of sensory affections and by the myasthenic reaction. It is true that myasthenic patients may also be hysterical, but as a rule this does not seem to be the case. Yet, unfortunately, at least one case of fatal myasthenia gravis has been diagnosed as hysteria.

From ordinary bulbar paralysis.—Myasthenia gravis is distinguished from ordinary bulbar paralysis by the involvement of the upper as well as the lower half of the face, by the affection of the limbs and trunk, by the myasthenic reaction, and by the variations in the severity of the symptoms. In pseudo-bulbar paralysis the limbs may be affected, but their condition is one of diplegia rather than flaccid paralysis, they are rigid, and show the ordinary signs of descending sclerosis. In bilateral facial paralysis the tongue and also the ocular muscles, with the exception of the orbicularis, are unaffected. The nerves give the

[4] Brain, No. 90, vol. xxiii.
[5] Boston Medical and Surgical Journal, Dec. 20th, 1900.
[6] "Functional Dysphagia," THE LANCET, Dec. 3rd, 1898, p. 1463.

electrical reaction of degeneration which is absent in myasthenia gravis. The facial type of myopathy somewhat resembles the appearance in myasthenia gravis. But myopathy is progressive or stationary and not remittent, the tongue, pharynx, and larynx, and, almost invariably, the ocular muscles with the exception of the orbiculares escape. In superior nuclear palsy (polio-encephalitis) the ocular and bulbar muscles may be paralysed. But here, again, we do not meet with the remissions of symptoms which characterise myasthenia gravis. Also superior nuclear palsy is frequently associated with syphilis, tabes, or general paralysis of the insane, but this association has not been found in myasthenia gravis.

From diphtheritic paralysis.—Myasthenia gravis is perhaps more likely to be mistaken for diphtheritic paralysis than for any other disease. A nasal voice, regurgitation of fluids through the nose when swallowing is attempted, are well-known symptoms of paralysis of the soft palate, and they occur almost without exception in cases of diphtheritic paralysis. In this disease, moreover, paralysis of the extrinsic and intrinsic ocular muscles, of the pharynx and glottis, and of the intercostals and diaphragm are extremely common. General muscular prostration, easily induced fatigue, are observed in diphtheritic paralysis and in myasthenia gravis alike. In both diseases we see sudden onsets of dangerous cardio-pulmonary crises, which may subside, but which often prove fatal. In myasthenia gravis, however, respiratory failure is most common and in diphtheritic paralysis cardiac failure. A most important point of distinction is that the knee-jerks in diphtheritic paralysis are, as a standing rule, absent, although for a brief period they may be exaggerated. In myasthenia gravis they are usually active. In a few cases they have been sluggish and in some they have been exhaustible on repetition. In no case have they been reported entirely absent. The myasthenic reaction is absent in diphtheritic paralysis, but faradaic excitability is diminished, and in some cases the ordinary reactions of degeneration are present. The history of a previous sore-throat is, of course, all important. Yet many cases diagnosed as diphtheritic paralysis have no such history, and possibly some of them may have actually been cases of myasthenia gravis. The following is probably an example.

A boy, aged 11 years, was an in-patient at the Hospital for Epilepsy and Paralysis at Regent's Park Hospital from April 14th till Oct. 8th, 1893, under the care of Dr. A. Hughes Bennett. In the latter's absence I frequently had charge of the case, and regarded it as one of diphtheritic paralysis without evidence of preceding diphtheria. But Dr. Bennett's more cautious diagnosis was "dysphasia and nervous debility." The boy was discharged "much improved." In April 1894, however, he was re-admitted to hospital by Dr. W. Aldren Turner who noted "general feeble action of facial muscles, paresis of both orbiculares and frontales muscles, pupils dilated, no cycloplegia, cannot whistle or pout lips; tongue not protruded as much as it should be; nasal voice, but palate acts normally, weakness of upper and lower limbs general, especially of trapezii and deltoids, knee-jerks elicited with difficulty; feeble action of facial muscles to faradaism." On April 25th attacks of dyspnœa commenced and continued at intervals until the patient died in one of them on May 24th, 1894. Dr. Turner made a post-mortem examination and found the cerebro-spinal system absolutely healthy in appearance. At the time neither he nor I were acquainted with myasthenia gravis and could only regard the symptoms as due to an extremely unusual form of diphtheritic paralysis; unusual in its long duration (more than a year) and in the occurrence of a fatal relapse after a period of remission lasting several months.

The average duration of myasthenia gravis (in fatal cases) is one and a half years, but diphtheritic paralysis rarely lasts beyond a few weeks, during which the symptoms are fairly constant and (with the exception of the dangerous respiratory and cardiac crises which come and go) gradually subside. The difficulty in making the diagnosis in early cases of myasthenia gravis is obvious; but when symptoms of supposed diphtheritic paralysis have lasted unusually long and relapses have occurred after apparent recovery the disease is probably myasthenia gravis and not diphtheritic paralysis. Sensory affections, such as numbness, tingling, and partial anæsthesia, may be of value in the case of adults as evidence of diphtheritic paralysis. These symptoms are usually absent in myasthenia gravis, but in a case recorded by Guastoni and Lombi[7] subjective sensations of heat occurred with formication.

From Landry's paralysis.—Landry's paralysis usually runs a more rapid course than myasthenia gravis. It seldom lasts more than a few days; the symptoms are steadily progressive and not remittent. Electrical reactions are said to be normal, myotatic irritability and superficial reflexes disappear, and sensibility is impaired.

From multiple neuritis.—The history of alcoholic, arsenical, and other toxæmic influences, also the presence of pain, hyperæsthesia or anæsthesia, tenderness in the course of nerves, local œdema, and glossiness or pigmentation of the skin, rapid wasting of the muscles, loss of tendon reflexes, absence of myasthenic reaction, distinguish multiple neuritis from myasthenia gravis.

From post-influenzal neuroses.—Some of the cases of myasthenia gravis in which the onset has been sudden and associated with fever, headache, photophobia, and general pains suggest an influenzal origin. Moreover, in the early nineties, when influenza was a far more virulent affection than at the present day, sequelæ in the shape of various forms of ophthalmoplegia, of paralysis of the soft palate, pharynx, and larynx, of various cranial nerves, and cardio-pulmonary seizures were not infrequent. The complete muscular prostration and general neurasthenia following influenza also resemble the conditions in myasthenia gravis. But apart from psychical and hysterical affections the post-influenzal paralyses in general are attributable to multiple neuritis or to definite myelitis affecting various segments of the cord, whilst in the case of myasthenia gravis the symptoms cannot be referred to such lesions.

Treatment.—The symptoms of the disease are always rendered worse by bodily exercise and mental excitement. Hence, complete rest for mind and body should be the aim of treatment. The patients are from the very first in imminent danger of death, and their relatives should be warned of this, otherwise the deceptive lulls in the symptoms may encourage fatal indiscretions. Medical attendants should remember that frequent physical examinations may have disastrous results. Meals should be small, easily assimilated, and given at short intervals. The use of the stomach tube is dangerous, and should deglutition become impossible rectal feeding is the only course to pursue. Stimulant methods of treatment by cold douching and faradaism are absolutely contra-indicated. Massage and galvanism have proved useless. None of the drugs hitherto employed appear really to influence the course of the disease. Strychnia has been used without benefit by Strümpell and Dr. Buzzard—my own patient improved under strychnia at first, but subsequently relapsed whilst still taking it. Thyroid and suprarenal extract have proved also ineffectual. Tonics, such as arsenic and iron, have no specific action. Perhaps a more extended trial of suprarenal extract might be worth making. Its probably complex nature and variation in its constituents according to the condition of the glands at the time the extract is made may account for its failure hitherto as a remedy. Other organic extracts, such as cerebrin, myelin, didymin, and ovarian substance may also conceivably be of service in a toxæmia which produces no visible changes in any part of the nervous system. Failing these medicaments, one can only hope that the toxin of myasthenia gravis may be traced to its source, isolated, and its antidote found in our chemical and physiological laboratories. For morbid anatomy has thrown no light on the nature of the disease.

Upper Berke'ey-street, W.

PTOMAINE POISONING OR PERFORATION?

BY E. KEMPSON BROWN, M.R.C.S. ENG., L.R.C.P. LOND.

ON Nov. 19th, 1900, I was called to see a woman who was said to have become suddenly unconscious. She was an albino, 27 years of age, of nervous temperament, and generally enjoyed good health. I found her lying on her back with her legs extended; her face was pale, her skin was hot to the touch, and her pulse was almost imperceptible. Her eyes were closed. When spoken to she made no reply, but opened her eyes, which were then seen to be expressionless

[7] Il Policlinico, Sept. 1st, 1900.

and vacant; her pupils were dilated and her eyeballs moved irregularly. Her respirations were loud and 20 per minute; her temperature in the axilla was 103° F. There were twitchings of the muscles of her neck and face, her abdomen was slightly tympanitic, and signs of pain were elicited on pressure. Physical examination of the lungs, heart, and liver showed nothing abnormal. After the lapse of an hour the patient was more conscious; her pulse was 140 at the wrist, of very low tension and irregular, and her temperature in the axilla was 105°. Subsequently she had rigors, her temperature fell progressively and was 99° five hours before death. Her extremities became cold, the surface of her body became clammy, and she had hallucinations with general nervous prostration. Diarrhœa and vomiting were frequent, the stools being offensive and dark-coloured. In three days she passed about a pint of dark-coloured urine containing phosphates and mucus but no albumin. A papular erythematous rash developed on the backs of her hands and wrists and a few spots on her abdomen and knees on Nov. 21st. Death occurred early on the morning of Nov. 22nd, about 86 hours from the onset of the first symptoms.

I ascertained the following facts from her friends. She had been poorly the previous week from the effects of menstruation and cold. On Nov. 17th she felt well and ate two beef sausages. Three other persons had also partaken of sausages the same night. Two of them suffered from diarrhœa and vomiting. The third ate very little and was not affected; she gave the rest of her sausage to her dog, which was violently sick 12 hours afterwards. The deceased was seized with severe pain in her abdomen and vomiting 12 hours after eating the two sausages; diarrhœa set in about 20 hours afterwards. At the post-mortem examination the abdominal cavity was found to contain about a pint of turbid fluid. There was exudation of lymph and there were recent adhesions between the omentum and intestines. The parietal peritoneum was smooth and there were no signs of inflammation. The peritoneum over the small intestines appeared to be intensely inflamed, especially in the region of the ileum; the upper part of the small intestine was markedly distended. The spleen and the posterior surface of the stomach were bathed in curdy lymph. The mucous membrane of the stomach was acutely inflamed over the cardiac portion of the greater and lesser curvature with numerous ecchymoses, and the external surface in these regions was likewise inflamed. In the upper part of the duodenum the mucous membrane showed petechiæ in the submucous tissue; the duodenum was dilated. The inner surface of the rest of the intestine was pale with a few pin-point nodules at the lower six inches of the ileum. The lumen of the appendix was occluded; there were no adhesions externally and no signs of recent inflammation in this region. In connexion with the left ovary there was a multilocular tumour of the size of a hen's egg containing clear fluid; there were no signs of inflammation around it. The right ovary showed commencing cystic formation. The Fallopian tubes and uterus were healthy; the bladder was normal; the kidneys, liver, spleen, and lungs were congested; the heart was normal; the brain was anæmic.

Remarks.—The points of interest about this case, I think, are the following: (1) the sudden occurrence of the semi-unconscious state; (2) the high temperature; (3) the absence of marked muscular weakness; and (4) the very intense inflammation in the peritoneum covering the intestine without any apparent inflammation inside from which the toxic irritant presumably extended. The peritonitis might conceivably have commenced over the cardiac portion of the stomach and so have progressively extended and become more general.

Andover, Hants.

A CASE OF CEREBELLAR HÆMORRHAGE PRESENTING WELL-MARKED EARLY CERVICAL OPISTHOTONOS AND KERNIG'S SIGN.

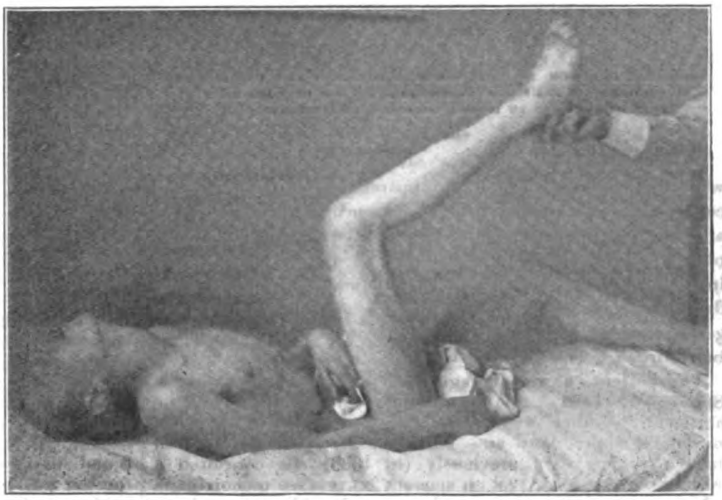
By WILLIAM THYNE, M.A., M.D. Edin.

A man, aged 20 years, with an epileptic history, was in his usual health on Christmas Day, 1900. After partaking of several hearty meals he was seized with vomiting, which continued through the night. About six hours after the onset it was noticed that the head was retracted (see Fig. 1) and the patient complained of severe frontal headache. There were no loss of consciousness, no motor paralysis, and no convulsions or twitchings, and the organic reflexes were unimpaired. The tendon reflexes were increased. Kernig's

Fig. 1.

Showing retraction of head.

Fig. 2.



Showing Kernig's sign.

sign was well-marked, as shown in Fig. 2. There was no ocular deviation. The condition of the optic discs could not be made out owing to the presence of traumatic cataract in the right eye and old keratitis in the left. The temperature was normal or subnormal except on the evening of Dec. 30th, when it was 102·6° F. The pulse varied from 60 to 160, but was regular in force and rhythm. There was no cardiac disease. On the 30th lumbar puncture was performed but gave a negative result. The patient remained in this condition, except for increasing weakness, till Jan. 4th, 1901, when he lost power in both legs, the right being the first affected. Consciousness remained unimpaired till death took place on Jan. 5th, 1901.

On the same day a partial post-mortem examination was made by Dr. R G. Riddell. The dura mater was thick but healthy. There was a serous effusion in the subarachnoid space which was very marked posteriorly. Over the right occipital lobe there was a thin layer of coagulated blood extending down to the cerebellum. The lateral ventricles contained about four drachms of clear serous fluid. The fourth ventricle was filled with blood-clot. There was a small hæmorrhage in the left lateral lobe of the cerebellum. There was no hæmorrhage over the base and no evidence of meningitis. The serous fluid from the subarachnoid space contained no organisms.

The sequence of events probably was as follows. A hæmorrhage occurring in the left lateral lobe of the cerebellum found its way into the fourth ventricle and thence through the foramen of Magendie to the subarachnoid space, the position of the hæmorrhage over the occipital lobe being probably determined by gravity. The case is interesting from the fact that well-marked cervical opisthotonos and Kernig's sign were due to cerebellar hæmorrhage, meningitis, with which they are usually associated, being absent.

Mr. S. G. Shattock very kindly examined sections of the cerebral lesion and found the arterioles free from any chronic disease in sections passing right through the seat of the hæmorrhage.

High Barnet.

A CASE OF PELVIC SARCOMA WITH CHYLOUS ASCITES; ABDOMINAL SECTION AND DRAINAGE; PATIENT WELL FOUR AND A HALF YEARS AFTER OPERATION.[1]

BY ARNOLD W. W. LEA, M.D., B.S. LOND., F.R.C.S. ENG.,

ASSISTANT SURGEON TO THE CLINICAL HOSPITAL FOR WOMEN AND CHILDREN, MANCHESTER; ASSISTANT TO THE PROFESSOR OF OBSTETRICS AT OWENS COLLEGE, MANCHESTER.

DURING recent years many cases have been reported in which abdominal tumours, apparently malignant, have ceased to grow and have sometimes entirely disappeared as a result of simple abdominal exploration. Our knowledge of the factors concerned in bringing about this result is very imperfect. In some instances inflammatory masses have doubtless been taken for new growths, but this cannot be the general explanation and it is well that all such cases should be recorded. The notes of this case are as follows.

The patient, a woman, aged 58 years, was first seen in September, 1896. She complained of swelling of the abdomen together with "bearing-down" pain. She had never been pregnant and she had always enjoyed good health. Ten years previously (in 1886) she consulted a well-known gynæcologist on account of profuse menorrhagia which was considered to be due to a fibroid tumour of the uterus. Three years later she herself could plainly feel a lump low down in the right side of the abdomen, but the menopause had come on and the swelling caused her no trouble. Early in 1896 she observed a rapid increase in the size of the abdomen and she also had pains in the pelvis associated with irritability of the bladder and pressure symptoms. She had also recently lost flesh considerably, though she was still well nourished and looked fairly healthy. Examination of the abdomen revealed marked distension below the umbilicus, especially prominent on the right side. A thrill was readily obtained and the distended part of the abdomen was dull, while the flanks were resonant. The physical signs were those of a large thin-walled ovarian cyst. By careful palpation firm masses could be recognised apparently within the cyst. A large elastic tumour was felt in the right inguinal region and another rounded mass in the right hypochondrium. On examination per vaginam the uterus was found to lie very low, the cervix reaching the vulval orifice. Douglas's pouch was bulged downwards. The uterus was small and pushed to the left side; the sound passed two and a quarter inches. The right side of the pelvis was filled up by a firm irregularly shaped mass occupying the broad ligament and continuous with the mass in the inguinal region. The body of the uterus could not be clearly defined as separate from the tumour. The left side of the pelvis appeared to be free.

Operation was performed on Sept. 25th, 1896, when the abdomen was opened in the usual way and the parietal peritoneum, which was somewhat thickened, was incised. This was followed immediately by the evacuation of a large quantity of chylous fluid, at first sight resembling pus. Seven pints of this fluid were collected. It had evidently been encysted between peritoneal adhesions. On introducing the hand a firm solid mass was recognised filling up the right side of the pelvis and iliac fossa. This was covered by peritoneum and had developed between the layers of the right broad ligament. The uterus was pushed away to the left and was quite small. The appendages were normal. The rectum was not pressed upon and the left side of the pelvis was free from growth. The mass on the right side extended upwards, with numerous irregularities and several large projecting masses, as high as the right hypochondrium. The tumours were deep red in colour and numerous large vessels ran over their surface. A pedunculated mass, of the size of an orange, projected towards the left side of the abdomen above the level of the pelvic brim. The cæcum and colon were displaced and lay external to the tumour and posteriorly. The small intestines were pushed upwards by the pressure of the ascitic fluid, and were matted together by numerous adhesions. The mesentery was apparently considerably shortened. The liver was normal in size and to the touch. The tumour was evidently beyond removal. An incision into the peritoneal capsule showed this to be firmly adherent to the surface and it was impossible to strip it off to any extent. The abdomen was flushed out with saline solution and an indiarubber tube was inserted.

The patient progressed very favourably. The discharge through the tube was very scanty. There was no rise of temperature. The tube was removed on the sixth day. The wound healed well. There was no accumulation of fluid, though the masses of the tumour were now plainly felt. The patient left the Nursing Home in three weeks feeling very well. Microscopic examination of the fluid revealed a granular basis of emulsified fat with a few leucocytes and red blood corpuscles. Since this time, nearly four and a half years ago, the patient has remained in good health and I have seen her at intervals. At the present time she is 63 years of age and feels well. The abdomen is lax and resonant all over. On palpation, however, small masses can be plainly felt in the right iliac region and also in the right hypochondrium. The uterus is small and atrophied. The mass in the right broad ligament is still present but is much smaller.

Such are the facts of this case and I have thought it of sufficient interest to record it in some detail. The primary tumour appears to have been a fibro-myoma of the right broad ligament. The history of a swelling in that region for ten years associated with menorrhagia, but without any evidence of implication of the uterus, shows that the condition cannot have been malignant from the first.

Fibro-myoma developing in the connective tissue of the broad ligament is rare, but many cases have been recorded. In 1885 Mr. Bland-Sutton collected details of 11 cases, some of which had attained a large size. Mr. Alban Doran recently removed one weighing 44 lb. The growths have always occurred in women over 35 years of age and are often bilateral. They often also grow with extreme rapidity. In some cases

[1] A paper read before a meeting of the Clinical Society of Manchester on Jan. 15th, 1901.

at least this has been due to infection from the bowel, as in two cases recorded by Mr. Bland-Sutton. In this instance the physical signs and appearances were those of a malignant tumour. Many examples of the origin of sarcomatous growths from uterine fibroids have been recorded (W. Williams, Doran, Langenhans, Leopold, &c.), although this is undoubtedly rare. Microscopically, the malignant growth is usually a spindle-celled sarcoma or shows embryonic spindle cells of connective tissue or myomatous origin. Cases of primary sarcoma occurring in the broad ligament are also recorded. I am not aware that as yet any case of broad ligament myoma becoming sarcomatous has been described, but judging from analogy with uterine tumours there is a possibility of this occurring occasionally.

The development of chylous ascites in this case is also an unusual feature. Chylous ascites is in itself very rare. In a recent paper by Dr. Halliday Croom[2] he was only able to collect 63 recorded cases, but no doubt many more have occurred. Under this heading some cases have been placed in which the fluid was not chyle but milky-looking fluid in the peritoneal cavity due to the presence of cellular elements of a malignant growth. In true chylous ascites there is obstruction to the lymphatic circulation. This is rarely due to obstruction of the thoracic duct; more commonly it is the result of contraction of the smaller lacteals close to the mesenteric attachment of the bowel. This may be brought about by the development of small nodules of malignant growth in the mesentery. In other cases it may be the result of cicatricial contraction of the mesentery, as in some forms of chronic adhesive peritonitis due to tubercle or secondary to chronic irritation of the peritoneum. Very rarely in England filaria is found as a cause of chylous ascites. It is of interest to note that in two cases at least[3] tumours of the broad ligament have been met with associated with chylous ascites. In one case recorded by Dr. J. Fenwick double papillomatous cysts of the broad ligament were found accompanied by numerous secondary growths in the abdomen and marked shrinking of the mesentery with adhesions between the parietal and visceral layers of the peritoneum. In a case recorded by Dr. F. J. Smith,[4] although tumours were present in the broad ligaments the physical signs were rather those of very chronic adhesive peritonitis, due primarily to irritation of a carcinoma in the region of the gall-bladder.

The influence of the operation in this case is a question of great interest. No satisfactory explanation has yet been given of the fact that atrophic changes undoubtedly occur in certain tumour formations as a result of abdominal section. Mr. F. Treves in recording some cases of this nature considered that the explanation may be found in questions of intra-abdominal pressure, a subject on which little is known at present. It has been observed that in most of these cases the tumours have been of connective tissue origin, to be classed therefore as sarcomata. These tumours, composed of embryonic connective tissue, have apparently in many instances a somewhat low vitality, and the slight inflammatory changes set up as the result of operation are sufficient to check active growth or even to cause their absorption. These tumours are comparable to the infective granulomata such as tubercle, which, especially in the abdomen, is well known to atrophy and even to disappear after abdominal section with or without drainage. In this present case, since four and a half years have elapsed since the operation without any increase in growth, it is obvious that the operation in some way inhibited the further development. The chylous ascites was probably attributable to a chronic adhesive peritonitis resulting from the irritation of the tumour and producing by shrinkage and adhesions obstruction of the lacteals. This process was also inhibited and now, at any rate, there is no lacteal obstruction; this is probably due to the development of fresh lymphatic channels. The growths in the abdomen have not disappeared. They are still present though causing no symptoms, and it is, of course, possible that at some future time renewed activity may commence in them.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A NOTE ON THE RESULTS OBTAINED BY THE ANTI-TYPHOID INOCULATIONS IN THE 15TH HUSSARS, MEERUT, INDIA.

BY A. E. WRIGHT, M.D. DUB.,
PROFESSOR OF PATHOLOGY, ARMY MEDICAL SCHOOL, NETLEY.

THROUGH the kindness of Lieutenant-General Sir George Luck, commanding the Bengal army, I am permitted to publish the following officially compiled statistical statement dealing with the effects of anti-typhoid inoculations in the case of the 15th Hussars:—

From Oct. 22nd, 1899, to Oct. 22nd, 1900.

—	Strength.	Number inoculated in England.	Admissions to hospital for enteric fever.	Deaths from enteric fever.	Number not inoculated.	Admissions to hospital for enteric fever.	Deaths from enteric fever.
Officers	22	19	0	0	3	0	0
N.C.O. and men	481	317	2	1	164	11	6
Women	36	24	0	0	12	0	0
	539	360	2	1	179	11	6

It would thus appear that the incidence of enteric fever in the inoculated was represented by 0·55 per cent. and the mortality by 0·27 per cent., while the incidence in the uninoculated was 6·14 per cent. and the death-rate 3·35 per cent.

Netley.

A NOTE ON AUSTRALIAN BITTER BARK (ALSTONIA CONSTRICTA) IN INFLUENZA.

BY J. GORDON SHARP, M.D. EDIN.

ONE of the drugs of the new Addendum to the Pharmacopœia is *Alstonia constricta* F. v. M., known as bitter bark, fever bark, or Australian bitter bark. It belongs to the same order as strophanthus—namely, *apocynaceæ* or the dog-bane order, and is a native of Queensland and New South Wales. It contains, perhaps, four alkaloids, one of which alone possesses any importance from the clinician's point of view, and it is known as alstonine. My specimen of alstonine is a dark brown amorphous body costing 3*s.* 9*d.* a gramme (15½ grains). For the present, then, alstonine is only known in the laboratory and it must become much cheaper before it comes within the domain of practical therapeutics. Both bark and alkaloid are intensely bitter and the former has been employed by foreign brewers to add bitterness to their ales. In the Australian colonies a decoction is said to be employed and is called by the name "bitters." Preparations of the bark have been employed as a general tonic and in certain stages of typhoid fever. The drug appears to act on the skin and kidneys as well as on the nervous system. The peculiar property of this bark appears to be that it resembles both quinine and strychnine. Physiologically it does not act on frogs like strychnine, but, like quinine, the alkaloid alstonine paralyses and finally kills amœba, paramœcium, and vorticella, but it is weaker than quinine.

The drug has been brought to notice by Dr. Joseph Bancroft of Brisbane, by Dr. Bixby of Detroit, U.S.A., and more recently in the *Pharmaceutical Journal* of July 8th, 1899, by Mr. J. H. Maiden, Government botanist at Sydney, New South Wales. *Alstonia constricta* must be distinguished from *Alstonia scholaris* R. Br., known as dita bark, or devil

bark, and belonging to the same order, and a native of India, of the Malay Archipelago, and of tropical Australia.

For over 18 months I have employed a tincture of the bark as a general tonic and more particularly in influenza. I start with it as soon as the feverish stage is over and give from five to 10 minims in chloroform water four times a day, preferably some little time before meals. Acting as it appears to do on the skin and kidneys it can be administered with safety even before convalescence has set in, seeing that it helps in the elimination of the poison. I can confidently recommend its use as a valuable agent in the treatment of influenza. Like every other drug it does not act in every case, but generally speaking one finds it useful. The Addendum dose of the tincture is from a half drachm to one fluid drachm. This is too much for a start, and I prefer to start with 10 minims or even in many cases with five minims, and, as I have said, chloroform water is the best vehicle.

Leeds.

DIPHTHERIA ANTITOXIN USED SUCCESSFULLY BY THE MOUTH.

BY W. CAMPBELL M'DONNELL, M.R.C.S. ENG., L.R.C.P. LOND.

IT being thought that the antitoxin of diphtheria must for successful exhibition be hypodermically injected the following may be useful.

A girl, aged 14 years, having both tonsils covered with a soft white pellicle and with no symptoms but a sore-throat, very slight enlargement of the related lymph glands, and a temperature of 38·2° C., at 11 A.M. on Nov. 12th, 1900, was given 1500 units of antitoxin by the mouth on the second day of the illness. The antitoxin had been issued by Burroughs and Wellcome in the dry state and was 20 months old. One patch yielded the diphtheria bacillus, as was certified by the medical officer of health. Within 20 hours of giving the antitoxin the right tonsil was quite clear. No application was made nor was any gargle used to the throat. On the third day there was no pellicle to be seen and at 11.30 A.M. the temperature was 35·8° C. On the fourth morning the temperature was 37° C. On the tonsil which was at first the most affected was seen a slight recurrence of pellicle. For this another 1500 units of the dissolved dry antitoxin were given by the mouth. She recovered uneventfully and as quickly as possible.

In an earlier case, where the struggling on attempting to hypodermically inject the antitoxin of diphtheria made that method impracticable, the antitoxin was rectally injected. The benefit was equal to that in the case described above. In this case, however, diphtheria was not bacteriologically proved, but clinically it was certain.

Stoke Newington, N.

A TUMOUR SIMULATING EPITHELIOMA WHICH APPEARED TO FOLLOW THE STING OF AN INSECT.

BY EDWARD J. WOOLLEY, M.B., B.C. CANTAB.

THE following case is of interest chiefly on account of the appearance of an uncommon causation, the tumour itself presenting no characteristics to differentiate it from epitheliomata from commoner causes and in more usual positions.

The patient was a labourer, 54 years of age. He was thin almost to emaciation, but said that he had always been so and that he had noticed no loss of flesh in the last few months. In July, 1900, he was stung, or bitten, on the external surface of the forearm by an insect which he described as "a green fly." A swelling of the size of a common nut appeared at the site of the sting and the patient rubbed it and attached no importance to it, thinking that it would go down. This, however, was not the case. Six weeks after the injury there was considerable itching in and about the swelling. The patient poulticed it and bathed it frequently with hot water. He noticed at this time that the swelling was getting larger. He continued his poultices and bathings until Dec. 14th, when he came to me. The tumour was then circular in shape and of about one inch in diameter, being raised above the surface of the surrounding healthy skin not more than one-sixteenth of an inch. The centre of the growth was hollowed out slightly and had the appearance of a dry ulcer. There was some hardness, but not the hardness to be expected in a malignant growth; and there was no pain. The glands in the axilla and the supra-condylar gland were not enlarged. The skin in which the growth was situated was freely moveable on the subcutaneous tissues. Although the history and the appearance of the growth were not strictly those of epithelioma, they seemed sufficiently so to call for its excision and on Dec. 20th I removed it, under ether, by an elliptical incision. I found the growth to be confined exclusively to the skin, and the tissues under it to be quite healthy and not at all adherent to the tumour. A microscopical examination showed the tumour to be a squamous-celled epithelioma with well-developed cell-nests—a typical epithelioma of the skin. I should add that no members of the patient's family on the male or female side have suffered from cancer.

LONDON HOSPITAL.

A CASE OF HYDATID CYST OF THE LIVER RUPTURING INTO THE TRANSVERSE COLON.

(Under the care of Dr. F. J. SMITH.)

EVACUATION of the contents of a hydatid cyst of the liver into the bowel is not a common occurrence; more frequently the cyst makes an opening into the general peritoneal cavity, or through the diaphragm into the pleural cavity, or into the bronchial tubes of an adherent lung. When, however, the intestinal route is chosen by the hydatid, suppuration generally occurs in the cyst, and recovery is often complete and permanent. For the notes of the case we are indebted to Dr. H. N. Clarke.

A man, aged 32 years, was on April 2nd, 1900, admitted into the London Hospital with jaundice. He stated that he had been quite well until November, 1899, when he had an attack of "biliousness" and "constipation." Ten days later he had severe pain across the lower part of the chest; the pain was sufficient "to double him up" but did not make him vomit; the next day he became jaundiced. These signs all cleared up in about a week. Since then he had had five attacks, all the same in character—viz., pain first and then jaundice. He described his stools as being "like white putty" during the attacks. His family history was good; there was no history of syphilis or gonorrhœa. He had always been a temperate man.

The patient was admitted to hospital during his sixth attack of jaundice; he was deeply jaundiced and was much wasted, but he did not know how much weight he had lost. On examination the heart was found to be normal; there was a good deal of general bronchitis, and there was some fulness of the upper part of the abdomen. The liver was enlarged and the edge could be felt about two and a half inches below the costal margin; the organ was tender and a rounded smooth lump three inches across could be felt in the epigastrium, rather more to the left than to the right of the middle line; there was no œdema of the abdominal wall. On palpation the lump gave the sensation of deep fluctuation. The stools were white and clay-like. The urine contained a trace of albumin; the specific gravity was 1040 and bile was present.

Three days after admission—viz., April 5th—the patient had a rigor; the next day he was seen by Mr. Mansell Moullin who advised an exploratory laparotomy. It was decided that this should be done as soon as the bronchitis had cleared up sufficiently to allow the administration of a general anæsthetic. On the morning of April 7th the lump in the epigastrium was observed to be much smaller, and

later in the day some large pieces of white translucent membrane were passed in one of the stools, which had been carefully sifted since the patient's admission. No hooklets or scolices were found. The temperature ranged from 102° to 98° F. From this point the patient made an uninterrupted recovery; the swelling in the epigastrium entirely disappeared, though the edge of the liver could still be felt when the patient left the hospital. The jaundice gradually faded away, the appetite improved, and the patient rapidly put on weight again, being discharged as cured on May 8th.

Remarks by Dr. CLARKE.—Though no hooklets or scolices were found, it nevertheless seems most probable that this was a case of hydatid of the liver which suppurated. The transverse colon probably then became fixed to the under surface of the liver by adhesions and the pus was thus able to make its way out of the abscess cavity into the gut.

Remarks by Dr. SMITH.—This case is an excellent illustration of the occasional expulsion of a hydatid by nature's own means. We had fully made up our minds that surgery afforded the patient the best chance and were only waiting a favourable opportunity for operation when the rupture took place. There could be no room for doubt as to the nature of the membrane passed per rectum, as it was totally unlike any other possible membrane, though it is somewhat unfortunate that no hooklets were found. I can personally only call to mind one other case in which a hydatid has been naturally evacuated with such a happy result; that was in a boy who without any symptoms worth mentioning or physical signs either coughed up from the lung the whole of a hydatid cyst in large fragments. I showed the patient and the membrane at a meeting of the local branch of the British Medical Association in 1899. I cannot add anything of value to Dr. Clarke's account of the present case.

QUEEN'S HOSPITAL, BIRMINGHAM.

A CASE OF RUPTURE OF THE THORACIC AORTA.

(Under the care of Dr. O. J. KAUFFMANN.)

THE very interesting case recorded below is remarkable in that rupture of the aorta apparently occurred without any local disease and without any special strain. It must be remembered, however, that rupture of the aorta is often a slow process. A small fissure may appear in the internal layer of the wall as the result of some sudden increase of pressure, but the tearing of the other coats may proceed gradually and no violent symptoms may be produced until the outer coat gives way. As to the wall of the aorta in this case a microscopic examination would be needed to render it certain that no morbid change was present. Rupture of the aorta may occur in young adults, as in a case recorded by Dr. J. Lumsden,[1] where a young woman, 23 years of age, died from rupture of the aorta after lifting down a box from a shelf, and apparently, from the description, there was only a slight change in the endothelium and in the subendothelial tissue. Occasionally the aorta has been perforated by an exostosis from a rib, as in a case recorded by Mr. E. A. Lightburne,[2] where a boy, 12 years old, died from this cause with extensive hæmorrhage into the left pleural cavity. For the notes of the case we are indebted to Dr. A. Stanley Barnes, late house physician.

A groom, aged 19 years, was admitted into the Queen's Hospital, Birmingham, under the care of Dr. Kauffmann, on Oct. 11th, 1900. No history could then be obtained, as he was almost unconscious and quite unable to answer questions. The history obtained next day was as follows. He always was a "delicate" lad, but had never suffered from any illness sufficiently severe to keep him in bed. For a month before admission he had complained of an aching and sometimes shooting pain in the lower part of the chest behind (about the level of the eighth dorsal vertebra); this pain was worse on exertion, but was not accompanied by cough nor was it increased on deep inspiration. He consulted a medical man about it on Sept. 20th and was given a bottle of medicine, no physical examination being made. The pain was better on the next day and did not trouble him again for a fortnight, when on its recurrence the treatment was repeated, but this time without benefit. Despite his vague pain he kept at his work until Oct. 11th. On this day, at about 2.30 P.M., soon after his dinner, he felt very bad, the pain having suddenly become much worse. He ceased work at once and started for home, catching an omnibus a few yards away; he did not have to run for the omnibus nor had he undergone any other strain that day. Five minutes later the guard noticed that he looked very bad and called a medical man who found him in a collapsed and pulseless condition. He administered three minims of liquor strychniæ hypodermically and sent him at once to the hospital in charge of the police. Neither from the patient nor his parents could any history of an injury to the chest, either remote or recent, be obtained. He had had no cough and had never complained of indigestion. There was nothing in the family history to suggest either syphilis or tubercle; the lad himself denied exposure to syphilitic infection, and the father (with whom he lived) strongly supported his statement.

On admission the patient was a lightly-built lad with very little subcutaneous fat and looking somewhat wasted. He was very pale, the lips having a faint bluish tinge and the conjunctivæ being anæmic. He was partly conscious but could not answer questions and tossed about moaning restlessly on the couch. The pulse was rapid and very small. The abdomen was rigid but not distended nor was there any dulness in the flanks; there was considerable tenderness in the left hypochondriac region; no viscera could be palpated. The chest was slightly deformed, the sternum being too prominent. It was at once noticed that the left side of the chest hardly moved with respiration and that the palpable apex-beat of the heart was in the third interspace in the right vertical nipple line. The left axilla was dull up to the level of the fifth rib, and above this a low-pitched tympanitic percussion note was obtained, reaching as far to the right as the middle line and upwards almost to the clavicle. Behind, the lower part of the left chest was dull as high as the seventh rib, and above this the dulness shaded off gradually to a normal note at the apex. Over the very dull area no breath sounds could be heard and vocal fremitus was absent, in the hyper-resonant area faint breathing with prolonged expiration was heard, and in the partly dull area diminished rather harsh vesicular breathing was heard. Over the right lung no alteration of percussion note was observed and breath sounds though harsh were vesicular. The "anvil-sound" was well heard over the third and fourth left spaces in front. There were no heart murmurs. The pulse was 120, the respirations were 28, and the temperature was 98·2°F.

Morphia was given subcutaneously and the patient was put to bed. He slowly improved and by the next morning was able to give his part of the history recorded above, the rest of it being supplied by his mother and father. On Oct. 12th (the day after admission) he was still very weak and pale, but quite conscious and less restless. The abdomen was rigid and slightly retracted with inspiration, the recti abdominis hardening with expiration; a tympanitic note was obtained all over the abdomen. There was a little tenderness in the left hypochondrium but none elsewhere. The physical signs in the chest remained the same except that the hyper-resonant area extended to the right edge of the sternum and was now of a higher pitch than before.

As the patient was evidently suffering greatly from the increased pressure in the left side of the chest it was decided to attempt to remove some of the air and blood. A trocar and cannula were thrust through the fifth space in the left anterior axillary line—i.e., at about the upper limit of the dulness. The trocar was withdrawn and a water manometer about 10 inches high was attached to the cannula. On releasing the clamp between the cannula and the manometer the water was at once forced up to the top of the manometer tube and then overflowed. A mercury manometer was therefore substituted and indicated at once a positive pressure of 35 millimetres of mercury with expiration. About two ounces of air and a quantity estimated at from 10 to 12 drachms of dark fluid blood were then withdrawn and the intra-thoracic pressure fell considerably; as, however, the tubes became repeatedly blocked by clots of blood the cannula was removed and the wound was closed. For the same reason the final reading of the manometer, just before withdrawing the cannula, was untrustworthy. An examination of the chest immediately after the tapping showed that the hyper-resonant note was now much less high pitched and did not quite reach to the right edge of the sternum.

On Oct. 14th there was slight fever (the temperature being 99·6°) but the general condition was much improved. For the first time a heart murmur appeared, a soft whiff at the

[1] Brit. Med. Jour., Jan. 7th, 1899, p. 21.
[2] THE LANCET, Jan. 11th, 1896, p. 99.

first left cartilage close to the sternum, accompanying the first sound; and a similar one immediately succeeding the first sound in the third right space at the point of maximum heart pulsation. The rigidity and tenderness of the abdomen had almost disappeared; there was more dulness in the left side of the chest, the whole axilla being dull, but the expansion was less diminished. On the 16th the patient was much better and the tympanitic note did not transgress the middle line. The upper part of the left chest as far as the third rib gave a loud tympanitic note, thence to the fifth rib a shallow tubular note, and below that was absolute dulness. The heart remained as before, but slight epigastric pulsation—probably representing the true apex beat—was now felt. At 9.20 A.M. on the 18th, whilst apparently doing well, he cried out suddenly with pain in the left side of his chest and became blanched and covered with a cold sweat. Dr. Stanley Barnes saw him within three minutes and at once gave morphia, but he rapidly sank, dying within 20 minutes of the onset of the acute symptoms. During this time the dulness in the left side rose much higher and the discolouration around the puncture wound was noticed by the nurse to be markedly increased immediately after death.

During the whole week that the patient was in hospital he neither vomited nor expectorated anything and only occasionally did he cough—a short, harsh, dry cough. The urine once only showed a trace of albumin—i.e., the day after admission; its specific gravity was normal and no casts or blood cells were found.

Necropsy.—At the post-mortem examination, which was made on Oct. 19th, the body was found to be thin, wasted, and very pale. There was considerable subcutaneous hæmorrhage around the puncture of the 12th, extending dorsalwards from it. On opening the chest the heart was seen to lie completely on the right side, the apex being one and a quarter inches to the right and the extreme border three and a half inches away from the middle line. The left lung came to the front in the subclavicular region; below this the front was occupied by fresh gelatinous blood-clot; between four and five pints of this were removed and then the source of it was discovered in the angle between the left lung and aorta, about the level of the eighth rib. There was a large false aneurysm consisting of fibrinous blood-clot, with red gelatinous clot internal to it, lying along the inner surface of the left lung and extending upwards nearly to the apex. It arose from an oblique tear across the descending part of the aorta; the rent had evidently existed several days, since it showed signs of inflammation and repair, slight but distinct. The lower part of the false aneurysm had broken through some lung tissue; elsewhere the blood was limited by condensed fibrinous clot and some thickened pleura which limited it in every direction except below, where the hæmo-pneumothorax had occurred. There was no sign of tubercle in the lungs or vertebræ, nor were any of the latter eroded. The aorta showed no sign of endarteritis either here or elsewhere. It appeared rather wide, its circumference measuring eight centimetres near the transverse part of the arch and six centimetres near the diaphragm; its walls were healthy but rather thinner than usual. The tear extended obliquely round nearly three-quarters of the circumference of the vessel. The heart was healthy. In the left kidney were some recent yellow infarcts. The tension in the left pleural cavity was such that the left side of the diaphragm was convex downwards towards the abdomen.

Remarks by Dr. BARNES.—I have thought this case worth reporting in full on account of its extreme rarity. I have never seen or heard of another case of rupture of the healthy aorta apart from injury or sudden strain. In this case the lad and his parents were certain that no kick or other kind of injury had been received. No disease could be found in the aorta post mortem, and syphilis in the case was put out of court as far as is ever possible by a history. A second point of interest is that he should have survived for a week after an extensive rupture of such a large artery; presumably a clot had formed at the site of the laceration and for the time being prevented further hæmorrhage, but after the arterial system had regained its tone a slight movement or temporary increase in the blood-pressure would be enough to wash away the feeble barrier and allow fresh hæmorrhage to occur.

Evidently one reason why the plug in the lacerated aorta remained in its place so long was that the difference between the pressures in the aorta on the one hand and in the pleura on the other was much diminished by the great increase in intra-thoracic pressure occasioned by the sudden large hæmorrhage, as well as by the great lowering of arterial blood-pressure which also accompanies a large hæmorrhage. The pressure recorded in the chest 20 hours after the hæmorrhage occurred was 35 millimetres of mercury during expiration (about 19 inches of water), which is, I believe, almost the greatest intra-pleural pressure on record. It is interesting to note that no heart murmur developed at the time of the dislocation of the heart but could only be heard after three days had elapsed; this fact is in keeping with many other observations of a similar nature made at the Queen's Hospital and elsewhere.

The preliminary diagnosis of hæmo-pneumothorax was easy and was confirmed by the aspiration of Oct. 12th, but the ultimate diagnosis—the cause of the condition—could not be definitely made. The diagnosis which found most favour was that of ruptured aneurysm of the aorta, but tuberculous, malignant, or other erosion of a large vessel in the lung or pleura was also thought to be a possible cause. Perforating gastric ulcer (adherent to and bursting through the diaphragm) was at first sight simulated, the tenderness and rigidity of the left hypochondriac region being very marked; but the lack of any history suggestive of gastric ulcer, the prominent signs of large internal hæmorrhage, and the nature of the fluid aspirated seemed together sufficient to negative this diagnosis. With regard to aneurysm our chief difficulties were the absolute denial of syphilis, the youth and good arterial condition of the patient, and the presence of pneumothorax; the last-named sign was explained post mortem by the extensive ploughing up of lung tissue by the escaped blood. The main arguments against pulmonary disease were: (1) the rapidity of the hæmorrhage, showing that there must have been a large erosion of a large vessel; and (2) the lack of any sign or history of lung trouble, there having been no hæmoptysis even after the pneumothorax had occurred. I need hardly add that the diagnosis of ruptured healthy aorta was not considered. The ruptured portion of the aorta is now preserved in the Pathological Museum of the University of Birmingham.

I have to thank Dr. Kauffmann for permission to publish this case and for much valuable help in the preparation of these notes.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

An Address from the Society to King Edward VII.

A SPECIAL general meeting of this society was held on Feb. 5th, Dr. F. W. PAVY, the President, being in the chair.

The PRESIDENT explained that the meeting was convened to consider the presentation of an address to the new sovereign by the society that was instituted now close on a century ago for the cultivation and promotion of medicine, surgery, and allied branches of knowledge, and received in approval of its laudable design from King William IV. a Royal Charter of incorporation in which the King declared himself, and his successors if they should think fit, the patron of the society. On the late beloved Queen's accession to the throne she followed in the footsteps of her predecessors and became the patron and by her special sympathy helped the achievements of medical art. The society had met to give outward expression to what was inwardly felt by all in an address of condolence, associated with an expression of hope that His Majesty would, in accordance with the terms of the Charter, graciously think fit to declare himself the patron of the society.

Mr. PEARCE GOULD, as secretary, then read the text of the address, the members all standing.

The PRESIDENT then called on Lord Lister to move the adoption of the address.

Lord LISTER felt it to be a great but an inexpressibly melancholy honour to propose the adoption of the address. In common with all the vast empire, and indeed with the whole world, they lamented the loss of a Sovereign pre-eminent in wisdom and in virtue, whose long reign was one constant, consistent effort to promote the good of her people and of all mankind. How signal had been the success with which that effort was crowned was evidenced by the

tributes to her greatness and goodness that had been pouring in from all quarters at home and abroad. It was fit that the only Royal medical society of the metropolis should give expression to their sense of grief at her death. The medical profession, whose object was to prevent or relieve the physical ills of mankind, appealed always to Her Majesty's warm and sympathetic heart, and if it were suitable to speak of loyalty of a Sovereign to subjects they might say that the medical profession never had a more loyal mind than it had in Queen Victoria. Those of her medical officers who had been privileged to attend upon Her Majesty would speak with one voice to that effect if they had been all alive to that day. Nothing could more strongly illustrate her complete confidence in her medical advisers than her submission to chloroform at a time when its use in midwifery was by no means generally recognised and when in influential quarters it was strongly opposed. Lord Lister believed that he happened to be the only person who ever exercised upon her sacred body the divine art of surgery. The occasion was a most critical and anxious one, but nothing could exceed her kindness and consideration, while she treated him with queenly dignity. Thus, the medical profession felt, perhaps, more than others the greatness of the loss they had sustained. There was, however, another side to the address. In the night of their deep sorrow they could see a most auspicious dawn. The King in his first Council meeting promised in words characterised equally by dignity and pathos that he would tread in the footsteps of his beloved mother, and that promise he had repeated in his message to his entire empire. Various kindly acts which he had been doing in the last fortnight indicated that the King had inherited the grace and tact of the departed Sovereign and it was known from his past life that he honoured and loved the medical profession—witness all that he had done for Guy's Hospital and witness the "Prince of Wales's Fund" in the prosperity of which he was known to take the keenest interest. Whilst, therefore, all condoled with him in his grievous sorrow they gladly congratulated him on his accession to his ancestral throne, confident indeed that he would be found walking in the footsteps of his mother, who as they believed had gone to her reward.

Dr. SYDNEY RINGER (in the absence of Sir WILLIAM CHURCH) seconded the motion for the adoption of the address.

The motion was carried unanimously.

PATHOLOGICAL SOCIETY OF LONDON.

Relative Agglutination Phenomena seen after Immunisation against the Typhoid Bacillus and its near Allies.—Agglutination of Plague Bacilli.—Formation of Urobilin from Bilirubin.—New Pathogenic Member of the Blastomycetes.—Bacillary Forms of Streptococci.

A MEETING of this society was held on Feb. 5th, Mr. W. WATSON CHEYNE, the President, being in the chair.

Dr. F. W. ANDREWES and Dr. H. A. SCHÖLBERG made a preliminary communication as to their Experiments on the Relative Agglutination Phenomena seen after Immunisation against the Typhoid Bacillus and its near Allies. Dr. Andrewes pointed out the importance of the quantitative factor in all observations on the power of agglutination; the degree of dilution in which the serum exhibited a clumping action had an important bearing in diagnosis. There were also theoretical points which might be elucidated by attention to the quantitative factor. It was desirable to learn the origin of the bacterial product which evoked the power of agglutination and the relationship between the powers of a given serum to clump the different members of the colon group of bacilli. Experimental immunisation against different members of the group offered the best chance of solving such problems. The questions attacked were: (1) Was the bacterial product which evoked the agglutinative reaction resident in the soluble toxins which could be filtered off from the bacterial culture or in the bacterial protoplasm itself? and (2) Was the reaction evoked by a product common to the different members of the colon group or by a product peculiar to each species? Klein and others had shown that there were intra-cellular poisons common to various species of bacteria; it was also clear that each produced its own specific toxins. In the experiments carried out (almost entirely by Dr. Schölberg) the aim was as accurate a quantitative estimation of the agglutinative powers as could be attained, and the results were exhibited graphically on plotted charts. The standard which was adopted was the upper limit of dilution which gave an approximately complete reaction within a time limit of one hour in living emulsions of bacilli prepared from recent gelatin cultures. The results of the experiments so far as they had yet been completed were as follows: (1) the bacterial product which evoked the agglutinative power resided in the bacterial protoplasm rather than the soluble toxin; (2) a share in the result was borne by a protoplasmic poison common to the bodies of allied bacterial species (for example, an animal immunised against the bacillus typhosus furnished a serum which would in lesser degree clump bacillus coli communis and Gärtner's bacillus); (3) in addition to this some specific intra-cellular substance was present which excited a higher degree of agglutinative power upon the particular species employed in the immunisation; and (4) the rabbit was found to be a more suitable animal than the guinea-pig for the development of the agglutinative power. Dr. Schölberg described in fuller detail the methods which he had employed in carrying out the experiments and the precautions which he had taken to avoid errors in the results. The toxin for the animal experiments was prepared in the usual way from broth cultures three months old and cultivations were made from it before inoculation to prove that the fluid was sterile, which was always the case. The bacterial injections were made from bacteria grown on dry agar entirely free from expression water. A suspension of a variable amount of an agar culture was made in sterile saline solution and heated to 70° C. for 15 minutes. Cultivations made from the bacteria injected were sterile. Broth cultures were not used in making the emulsions for agglutination tests, as these were unreliable. Gelatin cultures from 48 hours to 120 hours old were uniformly used for the preparation of the emulsions, which was done with sterile normal saline solution. The charts shown showed that the first agglutination occurred on the fifth or sixth day after inoculation with Professor Wright's sterilised typhoid broth cultures, bacillus coli and Gärtner appearing a day later as the typhoid maximum agglutination rose. The coli and Gärtner curves ran together, but independently of the typhoid agglutination curve. Inoculations in animals with pure typhoid toxin gave an average maximum dilution agglutinating power of 1 in 40 for typhoid, and coli and Gärtner were uniformly negative at that index—on one occasion only, when the typhoid index was 1 in 100, did coli and Gärtner agglutinate, and then only at a dilution of 1 in 10. Using the bacteria only in the case of typhoid the first agglutination appeared in the rabbit on the fifth day after inoculation, and bacillus coli and Gärtner on the sixth day. A maximum dilution of 1 in 500 for typhoid was represented by 1 in 50 for bacillus coli and Gärtner on the ninth day. Using guinea-pigs the reactions were not so high and showed that for the Gärtner bacillus when inoculated the reaction for typhoid and bacillus coli was uniformly negative, while the maximum agglutination for the Gärtner reached as high as 1 in 130.—Dr. HORTON-SMITH, Dr. WILLIAM BULLOCH, Dr. W. C. C. PAKES, Mr. S. G. SHATTOCK, and others joined in the discussion, and Dr. ANDREWES and Dr. SCHÖLBERG replied.

Dr. E. KLEIN made a communication on the Agglutination of Plague Bacilli. The difficulty of obtaining plague bacilli in emulsion was dealt on. Saline solution was the only medium with which he had succeeded. He had found that ordinary bouillon caused agglutination. Serum of rats that had been treated with Haffkine's serum and also that of rats that had been inoculated with plague bacilli and had recovered also agglutinated.—Mr. SHATTOCK observed that salt solution when added to blood prevented the corpuscles from forming rouleaux.

Dr. ARCHIBALD GARROD and Dr. J. H. DRYSDALE in a preliminary communication on the formation of Urobilin from Bilirubin showed that the process was far more obscure than was now generally taught.

Dr. KLEIN described a New Pathogenic Member of the Blastomycetes which he had isolated from milk. When injected into guinea-pigs subcutaneously it caused gelatinous tumours and glandular swellings. When injected intraperitoneally nodules in the liver, lung, pancreas, ovary or testes, and intestine followed. All the lesions contained vast numbers of the micro-organism and in the tissues some of the latter assumed hypha-like forms which were absent in the cultures. These blastomycetes stained readily and so differed from those described by Fullerton. They grew

better on alkaline than on acid media and in that differed from those described by Sanfelice, Roncali, and Plimmer.

Dr. M. H. GORDON drew attention to a Morphological Feature exhibited by Several Streptococci isolated from the Normal Throat to form here and there an individual that in shape resembled a bacillus more closely than a coccus. It was stated that in some cases these bacillary individuals were apt to bear a morphological resemblance to forms of the diphtheria bacillus, for which they might conceivably be mistaken unless due care was exercised. It was remarked that the significance of the phenomenon could only be properly understood by making systematic comparative observations in the course of which the other biological characters of these organisms were also taken into account. Lantern slides were shown of streptococci exhibiting bacillary forms.

Dr. ANDREWES and Dr. W. J. HORNE demonstrated the Collodion Method applied to Paraffin Sections for Class Purposes.

OPHTHALMOLOGICAL SOCIETY.

So-called Paresis of Divergence.—Eclipse Blindness.—Bullet Injury of the Occipital Lobes, with Loss of the Lower Half of Each Visual Field.

AN ordinary meeting of this society was held on Jan. 31st, Mr. G. ANDERSON CRITCHETT, the President, being in the chair.

Dr. G. A. BERRY read a paper on So-called Paresis of Divergence. He cited cases and showed diagrams in support of his theory that the cause was really overaction of convergence rather than paresis of divergence. In cases where there was doubt whether strabismus fixus was present or not the diagnosis was much facilitated by taking hold of the eye with a pair of fixation forceps and forcibly rotating the globe outwards. If this could be done it was clearly not a case of strabismus fixus, while if it were impossible then it proved that it was a true case. He also read notes on some rare forms of non-paretic, non-concomitant squint in which, through faulty innervation, muscles not usually associated worked together, such as the internal rectus of an eye with the superior rectus of the other.

Dr. RAYNER D. BATTEN reported a case of Eclipse Blindness with Thrombosis of a Retinal Artery and Hæmorrhage into the Vitreous. The patient was a woman, aged 28 years, who watched the eclipse on May 28th, 1900, without any other protection than that offered by screwing up the eyes and looking between her fingers held close together. Immediately afterwards she noticed that things looked black and the next morning she found that she could only see "portions of things." She was first seen on June 6th and was found to have lost the lower half of the field of vision in the left eye. The vision was $\frac{6}{18}$. Above the optic disc a white patch was seen, possibly an absorbing hæmorrhage, while the hazy and œdematous retina obscured the view of the disc and retinal vessels. The œdema increased until June 20th and then rapidly cleared, ultimately leaving a patch of choroido-retinitis above the disc. One of the upper retinal arteries was occluded and the others were reduced in size. The vitreous opacities cleared and the macula was unaffected. The vision improved to $\frac{6}{12}$ in the injured eye. In the right it was $\frac{6}{6}$. The patient was in good health and no other cause could be found for the injury except exposure to direct sunlight.—Mr. J. B. LAWFORD had observed three cases of eclipse blindness, but there were no ophthalmoscopic changes. In all, however, the scotoma had persisted with some deterioration of vision.—Mr. TREACHER COLLINS related two cases. In one the margins of the discs became very white and there was a central scotoma. In the other the vision improved, but the fields were greatly contracted for white and those for colours were very much smaller.—Mr. W. H. H. JESSOP had published three cases. In all the vision improved, though there was a slight permanent scotoma.—Mr. T. J. BOKENHAM gave details of two cases, in one of which there were retinal hæmorrhages. The vision improved from $\frac{5}{60}$ to $\frac{6}{12}$, but there was a marked central scotoma.—Dr. G. A. BERRY thought the scotomata were usually permanent in the worst cases. The general public was not sufficiently aware that blue glasses were worse than useless when looking at the sun and at bright lights. It was the blue and violet rays which did all the damage. In Russia red or yellow glasses were employed.—Dr. JOHNSON TAYLOR, considering the marked way in which Dr. Batten's case differed from eclipse blindness, asked if there was at any time keratitis punctata, as he thought the whole condition might be due to irido-cyclitis.—Dr. BATTEN, in reply, stated that no keratitis had been seen and he could find no cause for this condition other than that given.

The PRESIDENT described a case of Bullet Injury of the Occipital Lobes with Loss of the Lower Half of each Visual Field. The patient, a captain in the British army, was struck by a bullet (probably Lee-Metford) while turning to address his men on the left. The pain was likened to that caused by a blow from a racquet-ball. He lost his sight at once but did not become unconscious for half an hour. He remained comatose for eight days and on recovering consciousness was still blind, but a week later was able to distinguish the flash of a lighted match. He was trephined on the day following the injury, he believed at both the point of entry and exit of the bullet. The trephine aperture at the site of entry, marked by a distinct depression, was situated two and a quarter inches above Reid's base line on the right side in a vertical line above the posterior border of the mastoid process and one and a half inches below and slightly behind the parietal eminence, four inches from the external occipital protuberance. The aperture of exit was half an inch to the left of the middle line, two inches above the protuberance, and one inch below the lambda. When examined the pupils were active directly and consensually, the fundi were normal, and the vision in each eye was $\frac{6}{6}$ and Jaeger 1. The patient had been prevented from entering the navy by colour-blindness. The lower half of each visual field was lost almost completely, the line of limitation being irregular. This feature was the chief point of interest as it afforded evidence of interference with the cortical visual centres. The bullet must have traversed the skull horizontally from before backwards and from right to left, and brain substance had been recognised at the time of injury. The course of the bullet must have been through the anterior part of the right middle occipital convolution, injuring also the right and left cuneus. The sudden impact probably caused temporary paralysis of the visual centres from concussion. That there was a considerable extravasation of blood was proved by the rapid onset of unconsciousness, and this or the actual injury caused by the bullet may account for the persistent failure of the lower half of the visual fields, though on the latter supposition it is difficult to explain the exact symmetry of the visual loss. In a recent number of THE LANCET[1] Mr. Page had published a case of injury to the right occipital region attended with homonymous hemianopsia on the left side, complete at first, but subsequently recovering. No optic neuritis could be detected in either of these cases.—Mr. FISHER gave details of two cases of similar character to that cited, the lower half of the fields being lost—altitudinal hemianopsia.

The following cases and card specimens were shown:—

Mr. W. H. H. JESSOP: (1) A case of Tuberculosis of the Conjunctiva; and (2) a case of Probable Distension of the Frontal Sinus in a girl, aged 10 years.

Dr. W. A. STIRLING: A specimen of Primary Sarcoma of the Orbit.

Mr. W. LANG: New Growth on Ocular Conjunctiva, probably a papilloma.

Mr. J. B. LAWFORD: Concussion Injury of the Eyeball with a "hole" at the macula.

Mr. W. T. LISTER: Spreading Opacity of the Cornea following herpes ophthalmica.

Dr. W. C. ROCKLIFFE: Sections of a Conjunctival Growth. The nature of this being doubtful it was proposed to refer it to a committee.

KIDDERMINSTER MEDICAL SOCIETY.—A meeting of this society was held on Jan. 18th, Mr. J. Lionel Stretton, the President, being in the chair.—The President referred to the death of the late Queen and proposed a resolution of condolence.—The President read notes of three cases of Resection of the Intestine. In the first case the patient was a man, aged 64 years, who had been ruptured for many years, the rupture being always down and no truss being worn. Six months previously he had an attack of obstruction which was relieved. The present attack commenced seven days before admission to hospital; the patient refused to submit to operation at an earlier period. Under ether the sac was opened up and two strictures were found, one at the neck and

[1] THE LANCET, Jan. 19th, 1901, p. 156.

the other about the centre, the latter being so sharp and tight that it had reduced the calibre of the bowel to the size of a tobacco-pipe stem, and had so thinned the walls that fæcal matter was already escaping. The strictured portion of the bowel was removed and the ends were approximated with Murphy's button; the sac and testicle were removed. The man was discharged within a month well; the button was not found but soon after he left the hospital a hard motion was passed which was not examined. The hernia had not been down since. In the second case the patient was a female, aged 65 years, who had suffered from umbilical hernia for many years, no support being worn. She was very fat and her capillary circulation was bad. Strangulation took place 24 hours before admission to hospital. Ether having been administered an incision liberated several coils of stinking gangrenous intestine. 38 inches of the small intestine were excised and the ends were approximated with Murphy's button. The operation lasted about one and a half hours. She suffered considerably from shock and died six hours later in spite of saline transfusion and hypodermic injections of strychnine, &c. Nothing unexpected was discovered at the necropsy; the intestine was quite secure and the peritoneum was healthy. In the third case the patient was a female, aged 44 years, who had suffered from umbilical hernia for many years, but refused to wear a truss, as she was always able to return the hernia until six months ago, since which time a small portion had been irreducible. She was stout and plethoric with bad capillary circulation. Strangulation had existed for six days. Under ether, an incision disclosed a mass of adherent omentum and a coil of gangrenous intestine which had given way in three or four places and allowed free escape of fæcal matter. About eight inches of small intestine were removed and the ends were approximated with Murphy's button and returned into the abdomen. The operation lasted about one and a half hours. Death took place about 54 hours afterwards. At the necropsy the Murphy's button was found to be securely fixed and had not allowed any oozing; there were no signs of peritonitis.—Dr. Evans read notes of a case of Cancrum Oris. The patient was a male child, aged four years, who had had measles five weeks previously. The left cheek was considerably swelled, discoloured, and hard, and there was a slough of the size of a shilling inside the cheek opposite the last molars. There was much salivation, the breath was very offensive, and the pulse was weak and rapid. Under chloroform the sloughing area was well cauterised with Paquelin's cautery and afterwards swabbed out with fuming nitric acid; this treatment was repeated ten days later and again in four days, and again after the lapse of seven weeks. The child was now showing signs of improvement.—Dr. E. A. Naylor read notes of a case in which the President had removed a portion of the lower jaw for malignant disease.—The President read a very amusing paper on the Humours of the Profession and the meeting terminated.

Reviews and Notices of Books.

Bacteriology in Medicine and Surgery: a Practical Manual for Physicians, Health Officers, and Students. By WILLIAM HALLOCK PARK, M.D., Associate Professor of Bacteriology and Hygiene, University and Bellevue Hospital Medical College, and Assistant Director of the Research Bacteriological Laboratories of the Department of Health, City of New York. Assisted by A. R. GUERARD, M.D., Assistant Bacteriologist, Department of Health, City of New York. London: Henry Kimpton. 1900. Pp. xi.–693. Price 15*s*.

THE student of bacteriology has before him at the present day a considerable number of text-books, all more or less on the same lines, moderate in price and not too voluminous for his needs. Future editions will demonstrate which of these works are to survive in the struggle for existence. So many of them are of merit that the struggle must be a keen one, but amongst those which should be able to hold their own we are inclined to place the present volume. Professor Park's name is familiar in America, and some of his work is well known in this country. His wide experience in the practical applications of bacteriology, gained in the Research Laboratories of the Health Department of New York, has combined with his teaching experience and his wide knowledge of scientific literature to render his book one of exceptional usefulness. If the city of London had the wisdom and foresight to endow well-equipped research laboratories in science on the same scale as the city of New York has done a valuable impetus would be given to the scientific study of medicine and public health.

There is little in the scope and arrangement of the book that is novel or demanding of special comment. It is simply an ordinary text-book and it stands or falls just in so far as it fulfils ordinary requirements; we venture to think that it fulfils these very adequately. Like all text-books it is essentially a compilation, amplified as well as verified by the experience of the writer. So far as it is a compilation it strikes us as essentially an American and a German one—that is to say, we do not find references to the English or the French schools of bacteriology quite so numerous as they perhaps deserve. To take a single instance, we find in the chapter on Small-pox no reference whatever to the observations of Klein and of Copeman on the spore-bearing bacillus which they have demonstrated in the vesicles of variola and vaccinia, and no detail at all as to the successful production by Simpson, Klein, and others of typical vaccinia by the passage of variolous lymph through a series of calves. It is nevertheless true that the admirable acquaintance with German literature possessed by the writer renders his book so full and complete on the majority of subjects that few faults of omission can be ascribed to it. The experience of the author likewise stands him in very good stead, as is well shown in the chapter on Diphtheria, which appears to us as excellent a presentment of the subject in its most modern aspects as we have ever read. Nevertheless, we must dispute the statement that no authentic cases of the transmission of diphtheria from animals to man are on record. Mr. W. H. Power's observations on milk diphtheria go far to incriminate the cow in certain cases, and Dr. Bruce Low has brought forward facts to show that cats may transmit the virus to human beings.

The chapter on Tuberculosis is also one which appears to us of special excellence and great practical value, though more detail might have been given as to the methods employed by Koch in the manufacture of his new form of tuberculin. The section on the bacteriological examination of water is disappointing, and the statement that we can only examine at one time a few cubic centimetres of water by bacteriological methods is quite erroneous since the introduction of the method of concentrating the bacteria from a litre or more of water into a small compass by the use of a Pasteur filter. No mention is made of Parietti's method or its modifications in examining water for typhoid or colon bacilli. In the account of flagellum staining the only method described in detail is a modification of Löffler's somewhat cumbrous original one. Van Ermengem's infinitely better method, though mentioned, is not described, nor are any of the short and easy methods of recent introduction, such as Pitfield's or Muir's, even alluded to. A moderate number of misprints are present; in particular we would call attention to the substitution of "symmetrically" for "hermetically" on p. 23. There are two good coloured plates and 87 figures, mostly reproductions of microphotographs. These are not so good as might have been expected; the figures of flagella in typhoid bacilli are exceptionally poor.

If we have called attention to certain points in which we conceive Professor Park's book might be improved we have done so from a sense of duty and with the full knowledge that it is an easy thing to pick holes in another man's work. It is a much more pleasant task to congratulate the writer on

the general excellence of his achievement, which we can do in all sincerity. It may safely be recommended to all whom it may concern as an unusually full and complete guide to the medical aspects of bacteriology, and it owes a good deal of its value to its eminently practical character.

A Manual of Medicine. Edited by W. H. ALLCHIN, M.D., F.R.C.P. Lond., F.R.S. Edin., Senior Physician and Lecturer in Clinical Medicine, Westminster Hospital; Examiner in Medicine in the University of London and to the Medical Department of the Royal Navy. Vol. II. General Diseases—continued. London: Macmillan and Co., Limited. 1900. Pp. 380. Price 7*s.* 6*d.*

THE second volume of this manual contains a large number of papers on varied subjects: for example, diseases caused by parasites and by poisons introduced into the body, primary perversions of general nutrition, and diseases of the blood.

The section on Diseases caused by Parasites is under the joint names of Dr. T. W. Shore and Mr. James Cantlie and contains good descriptions of all the chief forms of parasites that infect man, especial attention being given to the Cestoda and Hæmatoda. Under "Diseases Determined by Poisons Introduced into the Body as Such," we find articles by Dr. W. H. Allchin and Dr. G. V. Poore on Food Poisoning, Alcoholism, Morphinism, Cocainism, the Metallic Poisons (phosphorus, arsenic, mercury, and lead), Various Gases, Sewer Gas, and Serpent's Venom. These articles are of varying merit, some being very good, whilst others, notably that on alcoholism and morphinism, are not up to the standard of the work in general. Some of the contributions, too, on "Autogenetic Poisons" show signs of hurried preparation. Dr. Allchin's remarks on "Retrogressive Changes—Necrobiosis" are very interesting and would give a student a comprehensive idea as to the nature of atrophy and of fatty and lardaceous degeneration, while we particularly note the sub-section on "Senility" as containing much useful information. Dr. W. S. Lazarus-Barlow is responsible for the section on "Inflammation and its Sequels." This is by no means an easy subject to write upon, but the author has succeeded in presenting his readers with a capital summary of our present knowledge of inflammation, its signs, causes, varieties, and sequels. Professor J. Rose Bradford writes an excellent series of articles on the General Physiology and Pathology of Ductless Glands, on Cretinism and Myxœdema, Exophthalmic Goitre, and Addison's Disease.

The section on Diabetes Mellitus is by Dr. Bertrand Dawson. In speaking of the pathology of the disease he draws attention to the fact, which has only comparatively recently been fully recognised, that in patients afflicted with diabetes mellitus the power of sugar destruction is less than in health. This should have an important bearing on treatment. Dr. Dawson's remarks on treatment show sound judgment and the most modern views. He points out that the removal or retention of carbohydrates in a diabetic diet is a matter of moment and attended with disadvantages as well as advantages. The disadvantages are the difficulty of maintaining nutritive equilibrium and the ill-effect on appetite and spirits of the patients of the withdrawal of some of the most cherished articles of food, especially bread. A large number of diabetics can take some carbohydrates greatly to their advantage, and the amount must be accurately ascertained by frequent examinations of the urine. Dr. Dawson likewise contributes the article on Rheumatoid Arthritis and gives a clear and comprehensive account of this condition. We are glad that he has only given one synonym—viz., arthritis deformans—and discards the terms "osteo-arthritis" and "rheumatic gout," the last named especially being open to numerous objections.

A sound disquisition on Gout is from the pen of Dr. A. P. Luff, whose observations on treatment are particularly worthy of note, for many useful hints will be found in them, not only in reference to the treatment of the disease as it usually manifests itself, but also as regards the management of the irregular forms. Dr. Louis Jenner contributes an interesting account of the Blood under Normal Conditions and the Methods of Examining it Clinically. This subject is just now commanding a good deal of attention and Dr. Jenner's comments will be read with much interest.

One of the best sections in the book is that on Diseases of the Blood, by Dr. Sidney Coupland. From the time when Dr. Coupland delivered the Goulstonian Lectures on Anæmia in 1881 he has been a recognised authority on the variations of blood in disease, so that his contribution has the value of being the outcome of many years of personal observation. The anæmic group of blood diseases and the hæmorrhagic group are fully described, their pathology, clinical character, and treatment being considered at length. Under the first-named group Dr. Coupland places chlorosis, pernicious anæmia, leukæmia, splenic anæmia, and Hodgkin's disease; and under the second hæmophilia, purpura, scorbutus, and paroxysmal hæmoglobinuria. So much has recently been added to our knowledge on the pathological conditions of the blood that a summary of the investigations of various authorities is most welcome, and when to such a summary there is added a large clinical experience we obtain a really valuable monograph.

Other contributors to this volume are Dr. Bertram Abrahams, who writes on Myalgia and Myositis Ossificans; Dr. J. A. Coutts, whose article on Rickets is full of useful knowledge; and Mr. Raymond Johnson, who is the author of several good sections, for example, the articles on Acromegaly, Hypertrophic Pulmonary Osteo-arthropathy, and Osteomalacia.

This volume contains an account of many morbid conditions which are but very briefly touched upon in most text-books, and the efforts of the editor and his contributors will, we hope be duly appreciated by the medical profession.

The Histology of the Blood, Normal and Pathological. By P. EHRLICH and A. LAZARUS. Edited and translated by W. MYERS, M.A., M.B., B.Sc.Camb., with a Preface by Professor G. SINS WOODHEAD. Cambridge University Press. 1900. Pp. xiii.-216. Price 5*s.*

THERE is probably no scientific subject to which Professor Ehrlich has devoted his serious attention without making brilliant contributions to our knowledge. Modern hæmatology is under a deeper obligation to him than to any other worker in the field, for his classical researches upon the varieties of leucocyte present in the blood, based upon the methods of differential staining which he devised, form the foundation upon which all subsequent progress has rested. This book is a translation of the first part of "Die Anæmie: Nothnagel's Spezielle Pathologie und Therapie, vol. viii.," and the late Dr. Walter Myers has carried it out under the personal supervision of Professor Ehrlich and has included in it certain valuable alterations and additions.

Dr. Myers is the brilliant young physician who recently lost his life at Para whilst making investigations for the Liverpool School of Tropical Medicine into the etiology of yellow fever. The service that he has rendered to English readers by this translation is a very great one. The work has been recognised in its German dress as one of standard authority and it has lost none of its value in the translation. In spite of its small size it contains a more complete, thorough, and scientific account of the blood than any work in the English language with which we

are acquainted, and it has, above all, a certain quality to which we can apply no better word than "fundamental." That is to say, it always strives to exhibit as clearly as possible the principles which lie at the root of the matter under consideration. For this reason, even where the root of the matter is as yet unattained, the book possesses a faculty too often missing in more pretentious works—that of a suggestiveness which should go far to stimulate further work on the lines laid down.

The following is a brief outline of the manner in which the subject is treated. The introduction deals with the clinical investigation of the blood—i.e., with the volume of the blood, the number of corpuscles, the specific gravity, alkalinity, coagulability, and kindred matters. The morphology of the blood is then described in detail and the methods of its investigation are fully dealt with; the theory of blood-staining is explained in a most luminous manner. The normal and pathological histology of the red corpuscles is then discussed, after which comes the most important and the largest section of the book—that devoted to the leucocytes. Each form of leucocyte is described in full and its place of origin carefully considered. Naturally the nature of the cell granules receives the attention due to so important a subject. Next comes a consideration of the conditions under which the leucocytes are increased in number, perhaps the most suggestive section in the whole work. After discussing the biological importance of leucocytosis, its forms are dealt with under three headings—first, polynuclear neutrophil leucocytosis; secondly, polynuclear eosinophil leucocytosis; and thirdly, leukæmia, which is described as a "mixed" leucocytosis. It has been customary to regard leukæmia as a thing different in its essence from ordinary leucocytosis, but it is impossible to read these pages without feeling the force of the arguments showing its correspondence with the active leucocytoses. After a short account of leucopenia a bibliography and index conclude the book.

The work is illustrated by three plates, uncoloured, but good. They illustrate, however, comparatively unimportant points in the histology of the blood. It would, in our opinion, have been a great gain to the student had the descriptions been illustrated more copiously by good coloured plates. We know, however, the enormous expense of such illustrations. The translation is admirable in style and reflects great credit on the late Dr. Myers—indeed it is as readable as if originally written in English. There are too large a number of misprints. The preface by Professor Sims Woodhead is an excellent introduction to the subject and we cannot doubt that, as he says, this book must be looked upon as influencing the study of the blood more than any which has yet been published.

Essentials of Practical Bacteriology. By H. J. CURTIS, B.S., M.D. Lond., F.R.C.S. Eng. London: Longmans, Green, and Co. 1900. Pp. 291. Price 9*s*.

THIS is an elementary laboratory book for students and practitioners which in its plan and general "get up" reminds us of a similarly entitled book by Professor W. D. Halliburton, "The Essentials of Chemical Physiology." It belongs to the excellent series of "Essentials" published by Messrs. Longmans for students and practitioners. Primarily the work is intended for those seeking the diploma in public health, but we are glad to find that the author, without unduly burdening the volume, has paid attention to the special needs of clinical bacteriologists. A considerable amount of detail has been given in dealing with certain subjects, notably ringworm and cancer, and the author thinks some objection may be taken to his more ample treatment of these topics. He has, however, made exceptions in these cases in the hope that the chapters will provide a starting point for research in the directions indicated by the application of modifications of methods and media already known. Accordingly this portion of the subject is intended for advanced students only. The work is divided into Part I., dealing with the preparation, or manufacture as the author prefers to call it, of the nutrient media and with general technique, and Part II., dealing with the systematic study of the micro-organisms, both non-pathogenic and pathogenic. The book is eminently practical in the treatment of the subject and should do good service in placing before bacteriological students the best and most reliable methods of practice. Illustrations of the various organisms are given and examples of staining are also given which are admirably reproduced. On page 51 the example is spore staining by Möller's method. On page 141 the example is tubercle bacilli in a centrifugalised deposit from urine stained by Ziehl-Neelsen's method. The examples on page 151 are in the one case bacillus lepræ in discharge from an ulcer on the great toe, and in the second, bacillus lepræ in lepra cells in skin, both stained by Ziehl-Neelsen's method. We are glad to find that the author has in Lesson XXIII. given the bacteriological methods for testing antiseptics and disinfectants. The appendices deal with the requisites for a good bacteriological microscope, the methods for fixing, hardening, and imbedding tissues; and lastly, two useful tables for reference and a recapitulation of facts. The series of lessons is good, and the whole work we have found most instructive upon the applied side of the subject.

A Manual of Clinical Diagnosis by means of Microscopic and Chemical Methods, for Students, Hospital Physicians, and Practitioners. By CHARLES E. SIMON, M.D., late Assistant Resident Physician, Johns Hopkins Hospital, Baltimore. Third edition, thoroughly revised. Illustrated with 136 Engravings and 18 Plates in Colour. London: Henry Kimpton. 1900. Pp. 558.

IN reviewing the third edition of a work no words are required from us to explain its general scope. The fact that the first edition was published only in 1896 is sufficient proof that the author's efforts to supply a want for a book of this nature have met with favourable recognition. Since Dr. Simon first wrote this manual great changes in regard to clinical laboratories have taken place. Such institutions are now numerous and are regarded as being adjuncts to medical education as important as chemical and pathological laboratories, and the classes in "practical medicine" at the various schools include instruction in the use of the microscope and chemical methods. A study of the volume will show that in this edition the work has been thoroughly revised, much new matter added, whole sections have been re-written, methods rendered obsolete by the rapid advances of the science have been replaced by those representing the latest progress, and new illustrations added when necessary.

The first chapter describes the Examination of the Blood, and our remarks are exemplified by a perusal of its 121 pages. All the methods employed are fully up to date; for example, the estimation of the amount of iron in the blood in Jolles's ferrometer is fully given. The account of the microscopic examination of the blood is also worthy of praise. We would especially draw attention to the account given of the behaviour of blood corpuscles towards the anilin dyes. The anæmic or polychromatophilic degeneration of the red corpuscles is duly considered and a beautiful plate is given illustrating the blood of pernicious anæmia. The differentiation of leucocytes, to which so much attention has recently been directed, is also well explained, although the matter is rather a complicated one. The method of applying Widal's serum test is duly given, Dr. Simon giving as his opinion that the test "is a most valuable aid in the diagnosis of typhoid

fever, but cannot be relied upon to the exclusion of other symptoms." In the chapter on the Examination of the Sputum a plate has been introduced showing eosinophilic leucocytes and free granules in the sputum from a case of bronchial asthma. These bodies, however, are by no means characteristic of the sputa of asthma; they are present in a large percentage of tuberculous cases. Teichmüller regards their occurrence as evidence of a defensive struggle on the part of the body.

The whole work is characterised by thoroughness and clearness of description and we predict that further editions will be called for.

Compendium of Insanity. By JOHN B. CHAPIN, M.D., LL.D., Physician to the Pennsylvania Hospital for the Insane. London and Philadelphia: W. B. Saunders and Co. 1900. Demy 8vo. Pp. 234. Illustrated. Price 5*s.* net.

THE present Compendium of Insanity is a useful and unpretentious work which will take its place among the many smaller manuals and handbooks on the subject of mental diseases of which the past two or three years have been so prolific. Though not likely to be much used in this country, it will probably be serviceable as an introduction to the more elaborate and comprehensive works of Spitzka and Kellog which have hitherto marked the more advanced lines of American psychiatry.

The standpoint of the author is metaphysical, the human mind being postulated as an "essence of which we can form no conception." He makes little of recent discoveries and advances in psychology and much of the old division of the mind into faculties on the basis of metaphysical speculation. The result is that the work is throughout marked by the stamp of the antique and the methods of the metaphysical. The clinical divisions into mania, melancholia, and dementia follow well-known lines without any attempt at psychological analysis or at correlation of psychical symptoms with pathological changes. Then follow short accounts of paresis (general paralysis of the insane), epilepsy, and the briefest reference to abnormal psychical states marked by automatism and loss of memory—a condition of great medico-legal importance. We seek in vain for any account of such conditions as moral insanity, hebephrenia, alcoholic and other toxic insanities, circular insanity, or the psychoses of the climacteric. Six photographic plates illustrating the physiognomy of various insane patients are intercalated in the text. The printing is large and clear and the text is readable. The work is one to be read with caution, as it is both defective in regard to facts and dates and much behind the times from a medical and scientific standpoint. It is partly directed at a lay audience.

LIBRARY TABLE.

Alcaloïdes Usuels. Par Dr. M. BARNAY. Paris: Société d'Éditions Scientifiques. 1901. Pp. 366. Price 6 fr.—This book, comprising two volumes in one, forms No. 39 of the "Petite Encyclopédie Médicale." Dr Barnay in an impassioned "ante scriptum" implores his readers not to skip the first chapter of his book although, as he confesses, they are very likely to do so. We have read the chapter in question which is chiefly taken up with pointing out that most modern therapeutical preparations are uncertain and contain very different amounts of the active drug which it is wished to give. He quotes as an instance of uncertainty a very favourite remedy known as "*baume tranquille.*" In this preparation we find, he says, "belladonna elbowing hyssop, tobacco flirting with lavender, which in its turn has henbane for a neighbour, while datura fraternises with St. John's wort and elder flowers, &c. 19 substances in all without, for the most part, any bond of action." Dr. Barnay concludes by saying that instead of crude drugs the well-defined active principles should be substituted. The body of the book contains an account of the various alkaloids and glucosides arranged in alphabetical order. Each section is headed by a summary of the diseases and symptoms in which the drug is found useful. Then follow a description of the alkaloid in question, its physiological properties, its therapeutic indications, the dose, the modes of using, and the toxicology. In many cases Dr. Barnay apparently recommends the use of the pure alkaloid, but in some cases that of its salts or compounds, such as cantharidate of potassium or hydrochlorate of codeine. It has always seemed to us that if any salt of an alkaloid is employed it should be that salt which is found in the crude drug, such as, for instance, tannate of caffeine, meconate of morphine, or lactate or igasurate of strychnine. And probably the natural salts are superior to the pure alkaloid, which does not exist as such in nature. Though we do not agree altogether with Dr. Barnay's views his book will be found very useful.

Lehrbuch der Anorganischen Chemie. Von Professor H. ERDMANN in Halle. Mit 287 Abbildungen, einer Rechentafel, und sechs farbigen Tafeln. (*Manual of Inorganic Chemistry.* By Professor H. ERDMANN. With 287 Illustrations, a Reckoning Table, and six Coloured Plates). Braunschweig: Druck und Verlag von Friedrich Vieweg und Sohn. 1900. Pp. 758. Price 16 marks.—The first edition of this manual was issued a little over two years ago, and in our review of that edition we pointed out that the author evidently inclined to the view that the purely mathematical portion of the science should be presented to the student before he has made any practical acquaintance with the subject. We dissent from this view, as we think that theoretical study is immensely facilitated by a preliminary glimpse afforded by a few simple experiments of the nature of chemical change. Professor Erdmann starts by discussing in the very first chapter decimal fractions and the use and value of logarithms. The chapter is preliminary to the discussion of mass and weight, physical change and temperature, which in their turn precede the chapters on atomic theory. The rest of the work is divided into a part dealing with Metalloids on page 76 and a part on Metals on page 475. The account of the present position of chemical theory is excellent. The author is evidently *au courant* with the work and investigation of English chemists, for again and again he refers to the contributions that Englishmen have made towards both the expansion of theory and the accumulation of fresh facts. The book is fully and well illustrated, while the coloured plates showing the spectra of gases and of the newly-discovered elements are striking in their exact representation of the coloured lines characteristic of various elements. The colouring is most admirable and true. Although the second edition contains somewhat rather more matter than the first, yet its size is still within the limits of a manual. Not only does the book present an excellent and clear account of the theoretical considerations, but it gives also in some instances a description of the more important technical processes. Though a *lehrbuch*, the author has managed to give within its covers a very comprehensive and lucid treatment of the subject, and the work is thoroughly up-to-date.

Year Book of Pharmacy, 1900. Edited by LOUIS SIEBOLD, F.I.C., F.C.S. London: J. & A. Churchill. Pp. 597.—The British Pharmaceutical Conference held its meetings last year in London and a number of interesting papers were read and discussed. The papers together with the discussions are published in the transactions which form part of the publication before us. The rest of the journal is devoted to the past year's advances in chemistry, materia medica, and pharmacy. We congratulate the committee of publication upon the thoroughness with which this heavy work of abstraction is done. Their task has been most useful and most instructive and renders the Year Book a

valuable source of reference on the progress of the subjects indicated. The introduction is an excellent *précis* of this progress.

The Microscopy of the More Commonly Occurring Starches. By HUGH GALT, M.B., C.M. Glasg., D.P.H. Camb. London: Baillière, Tindall, and Cox. 1900. Pp. 114. Price 3*s.* 6*d.*—This little work is the outcome of a most useful piece of research relating to the identification of the more commonly occurring starches. We hope that the author will go on further with his work and develop the subject on the admirable lines of this instalment. It is a fact that accuracy in regard to description and delineation of the commonest starch grains is the exception rather than the rule in most text-books on the subject. The author has taken micro-photographs of the various starches, employing in the first instance dark ground illumination and in the second instance transmitted light. He has thus obtained some remarkable results which are quite contrary to the illustrations usually portrayed. One paragraph on this subject we cannot resist quoting. It is so good and illustrates the spirit in which the author has conducted his research. "In the light of the usual illustrations of potato starch what I have just said may appear somewhat startling; but as to its correctness there is no doubt, and, unlike many elaborate experiments, it may be verified with very little trouble by anyone with even an elementary knowledge of microscopy. So prone is man to accept without question the statements and illustrations of previous observers that the most misleading descriptions and figures—not of starches alone but of many other objects—appeared, and still appear, in many of the standard works dealing with the most diverse subjects." How true this is. As we have said, we trust that the author will pursue this interesting line of investigation further and give us the same valuable record of his results. The book will be most useful to analysts and laboratory workers in public health. It is illustrated by 22 original micro-photographs.

Mother, Baby, and Nursery: A Manual for Mothers. By GENEVIEVE TUCKER, M.D. London: T. Fisher Unwin. 1900. Pp. 193. Price 1*s.*—We reviewed the first edition of this book in our issue of April 9th, 1898 (p. 1004), and can find nothing new in the present edition. The two best chapters in the book are the last two which are respectively entitled, "Nursery Pointers" and "Nursery Don'ts." The advice given upon feeding is sound and we are particularly pleased to see that the author insists upon the necessity of babies being allowed pure water to drink, and that milk is more a food than a drink. Great stress, too, is very properly laid upon the harm done by giving babies anodynes or soothing syrups. We are sorry to see that some of the advertisements bound up with the book set forth the virtues of various quack medicines and of a book written by a quack. Probably the publisher is to blame for this, but we think that Dr. Tucker might see to it that such advertisements are omitted in future editions.

ARMY MEDICAL SCHOOL, NETLEY.

THE winter session of the Army Medical School was brought to a close on Jan. 31st. Owing to the continuation of the war in South Africa there was no public function in the school and owing to the circumstance that the surgeons-on-probation of the Royal Army Medical Corps had only been enabled to spend two months instead of four at the Army Medical School the surgeons-on-probation of the Indian Medical Service alone competed for the prizes and medals. The prizes were distributed by the principal medical officer of the Royal Victoria Hospital in the presence of the surgeons-on-probation of the Indian Medical Service and of the following officers: Professor A. E. Wright, M.D. Dub., Colonel K. MacLeod, M.D. Edin., LL.D. Aberd., Lieutenant-Colonel W. E. Webb, M.D. Aberd., R.A.M.C., Major W. Dick, F.R.C.S. Edin., R.A.M.C., Major R. H. Firth, F.R.C.S. Eng., and Major W. W. Webb, M.D. Aberd.

Before handing the prizes to the successful competitors Colonel W. J. CHARLTON, the principal medical officer, addressed some well-chosen words to the assembled surgeons-on-probation who have been recommended for commissions as lieutenants in the Indian Medical Service. Colonel CHARLTON said: "It is my pleasing duty to-day to present the prizes to those who have been successful in the late examination, and in doing so I offer you my warmest congratulations on the distinctions which you have gained, which must be a source of much gratification and pride to each of you. I wish, however, to impress upon you the necessity of not discontinuing your studies now that your time at Netley has terminated. The real battle of life only begins on your leaving here, and your future success depends on the steady and earnest acquisition of knowledge which the prizes you receive to day should stimulate you to endeavour to obtain. You are about to join a service of which I have some knowledge and experience, gained during 15 years' residence in India, and I can with confidence assure you that it is one you have every cause to feel a pride in. The Indian Medical Service is an old and time-honoured one, with a fine history and great traditions, and has associated with it many eminent and distinguished names, not alone in the domains of medicine and surgery and the allied sciences, but in that of diplomacy also—names which have shed a lustre on your service that time will not easily dim. The Indian Medical Service has conferred, and is daily conferring, innumerable blessings on the population of India and has been largely instrumental in ingratiating us and our rule with the people of that country and in enabling us to extend our empire and consolidate our power; in fact, it has been a most potent factor in the government of that country. In conclusion, I need only say that it should be your aim and object to preserve a high ideal and to try to follow in the footsteps of the great men who have preceded you, to maintain at all times the honour and good name of your service as faithfully as you would your own, so that you may transmit the same unsullied and untarnished to your successors; and in doing so I have no doubt but that you will steadily and surely attain success, and that when the day comes for you to sever your connexion with India you will have the happy reflection that you have done your duty to God and man."

The following lists show the names of the successful surgeons-on-probation. Those of the Royal Army Medical Corps were nominated to the school by the Secretary of State for War on the recommendation of the medical schools of the United Kingdom, and on leaving Netley they were subjected to a qualifying and placing examination only.

INDIAN MEDICAL SERVICE.

List of surgeons-on-probation who were successful at both the London and Netley examinations. The prizes are awarded for marks gained in the special subjects taught at the Army Medical School. The final positions of these gentlemen are determined by the marks gained in London added to those gained at Netley, and the combined numbers are accordingly shown in the list that follows:—

	Marks.		Marks.
*C. W. F. Melville	6001	W. D. Pringle	5002
†R. McCarrison	5924	A. W. C. Young	4982
‡J. Masson	5530	J. G. G. Swan	4838
§N. S. Wells	5411	R. M. Dalziel	4565
W. M. Anderson	5349	J. J. Robb	4416
E. H. B. Stanley	5180	S. A. Ruzzak	4302
W. H. Leonard	5166	R. B. B. Foster	4182

* Gained the First Montefiore Prize of £21 and Medal.
† Gained the Herbert Prize of £20, the Martin Memorial Medal, the Second Montefiore Prize, and the Prize in Pathology presented by Surgeon-General W. Hooper, C.S.I.
‡ Gained the Maclean Prize in Clinical and Ward Work.
§ Gained the de Chaumont Prize in Hygiene.

ROYAL ARMY MEDICAL CORPS.

List of nominated surgeons on probation who were recommended for commissions in the Royal Army Medical Corps at the close of the eighty-first session:—

A. J. W. Wells.	J. V. Roche.
G. F. Sheehan.	A. J. Hull.
H. H. Scott.	R. V. Cowey.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 9, 1901.

The King's Message.

WITH that thoughtfulness and tact which distinguish great rulers of men His Majesty the KING has found time in the midst of his own personal sorrow to send a message to his people. The message is divided into three messages, the first being headed, "To my people"; the others "To my people beyond the seas," and "To the princes and people of India." In the first message, which is general in its direction, His Majesty refers in terms of gratitude to the "universal expressions of what I know to be genuine and loyal sympathy with me and with the Royal Family in our overwhelming sorrow. Such expressions have reached me from all parts of my vast empire, while at home the sorrowful, reverent, and sincere enthusiasm manifested in the magnificent display by sea and land has deeply touched me." Sympathy in sorrow is all that it is vouchsafed to the nation to give, and the scenes of last week were the visible expression of a very real and heartfelt grief. Neither the KING, nor any one in the funeral procession, nor any spectator, could mistake the genuine nature of the popular manifestation. The absolute silence, a silence which could be heard, of the vast multitude, as the gun-carriage bearing all that was mortal of our late QUEEN passed, spoke in language that could not be mistaken. "To my people beyond the seas" is the happily worded address of the second message. How has the meaning and import of these words widened since the close of the reign of our other great Queen. When JAMES I. came to the throne, on the failure with ELIZABETH of the Tudor dynasty, the only possession of Britain beyond the seas was the plantation of Virginia. And now from lands unknown and undreamt of in those days, the sons of the blood have come to give their lives in South Africa for the empire's cause. How appreciated is their loyalty His Majesty's words fully show. The third message was as happy in wording and direction as the others. The great Empire of India in our recent seasons of national trouble has not been behindhand in fealty. Though it has been denied to the natives of that empire to show their loyalty by fighting, yet the feudatory princes sent their treasure, and those in a humbler rank came forward to perform an inestimable service, a service which had no lust of battle or excitement to spur them on, but one which wanted bravery as much, if not more than any other—the task of collecting and of removing the wounded. Gladly, we know, would the warrior tribes of India have fought under our flag, but this might not be. Let us never forget the services of the Indian dhoolie-bearers. And so to India, its princes and its people, the KING sends greeting and his promise to "endeavour to follow the example of the first Queen-Empress to work for the general well-being of my Indian subjects of all ranks and to merit as she did their unfailing loyalty and affection."

If the glory and the opportunities of empire are great, so also are its burdens and responsibilities. The ruler of the gigantic empire of Great and Greater Britain is not, however, we are proud to think, alone in bearing his burden. He is supported by the love and loyalty of a free people. And to no section of his subjects can King EDWARD VII. turn with more distinct assurance of support than to the members of our own profession. His Majesty's interest in medical matters is known to all. We are proud to think that he is a Fellow of the Royal College of Physicians of London and of the Royal College of Surgeons of England, while he has shown his esteem of medicine in a wonderfully practical manner. As PRINCE of WALES he was President of the oldest hospital in these islands. He was chairman of the Royal Commission on the Housing of the Poor, a question the solution of which medical and sanitary authorities alike are convinced will be one of the greatest steps forward that our civilisation can take. As originator and chairman of the Prince of Wales's Fund for the London hospitals he raised a lasting memorial to the Diamond Jubilee of Queen VICTORIA, and associated that memorial with medicine. The exacting duties of his high station may not allow him as heretofore to take such an active part in works of philanthropy and charity, but we are certain that his interest in such will be as keen as ever. And he may rely that the PRINCE who served a worthy apprenticeship to the throne by endeavouring to follow the lives and assuage the sorrows of the poorest of his subjects will, as KING, always command the deep and personal esteem of the medical profession.

Legislation against National Intemperance.

IT is sometimes said that the members of the medical profession show a want of courage in the expression of their knowledge of the drinking habits of the nation and of the mischief that is done thereby. There may be some grounds for the reproach but not much. Since the days of Dr. R. B. TODD, a generation back, no leader of medical thought has sanctioned a reckless use of alcohol in any form. And not a few of the men in the front rank have spoken with plainness on the subject and have reduced their prescription of alcohol to the lightest forms and the most modest quantities. The insurance offices, acting as much under the advice of their medical officers as in accordance with their own special and costly experience in the matter, make the question of moderation in the use of alcohol a cardinal one, and unhesitatingly either reject altogether proposals from persons unable to show that they are properly restricted in their use of alcohol or attach such conditions to acceptance of their proposals as to mark their belief that the absence of moderation involves, in the majority of cases, a premature claim on the funds of the association. The significance of this fact is great. For there is in the business of life insurance the keenest competition, and no fancy objections would be raised to the acceptance of any reasonable proposals. The charge against medical men that they have been timid in testifying to the injurious effects of

more than a moderate use of alcohol while lay bodies have widely recognised these effects is not without foundation. But the public utterances of PARKES, MURCHISON, GULL, and ANDREW CLARK, among others, laid stress on the harm done by even moderate quantities of alcohol to many persons. Of recent and living authorities we may refer to Sir J. BURDON SANDERSON, Sir HENRY THOMPSON, Sir WILLIAM GAIRDNER, Mr. VICTOR HORSLEY, and Dr. ROBERT HUTCHISON as men of scientific light and leading who have spoken out. The last-mentioned author, in his book on the principles of dietetics, in the course of a general review of the action of alcohol in health and disease, written in a strictly scientific and temperate sense, concludes that alcohol is an unnecessary article of diet in complete health, and quotes the following sentences from Dr. MURCHISON which may or may not be familiar to our readers: —

"1. A man in good health does not require alcohol and is probably better without it. Its occasional use will do him no harm; its habitual use even in moderation may, and often does, induce disease gradually.

2. There are a large number of persons in modern society to whom alcohol even in moderate quantity is a positive poison.

3. In all conditions of the system characterised by weakness of the circulation the daily use of a small quantity of alcohol is likely to be beneficial at least for a time."

It is, we are glad to think, foreign to the disposition of medical men to enter into political controversy on public questions. But in regard to the question of alcohol it is scarcely possible that they should remain altogether silent. The growing number of deaths from alcoholism and the increasing consumption of it by the people, men and women, and especially women, make it incumbent on medical men who have studied the question to place their views clearly before the public. We have received a copy of an address by Dr. WILLIAM CARTER of Liverpool on National Intemperance, who has clearly perceived the necessity for speaking out. Dr. CARTER does not go into any fine questions concerning the slight effects of moderate quantities. He speaks as a leading consulting medical man and a justice of the peace of Liverpool, in which city there is a constant and hard struggle on the part of the authorities with the social conditions that produce degeneration and disease. He probably holds views on the use and abuse of alcohol more severe than those of the majority of medical men who have to deal with the world as they find it, whether their patients are to be found chiefly in comfortable homes or in charitable institutions; but he wisely confines himself to palpable facts. He points out that in nearly every direction preventable disease has been prevented on a large and satisfactory scale since the legislation of the seventies, which divided the kingdom into sanitary districts and authorised the placing of them under the supervision of a medical man whose function it was, and is, to inquire into the existence of disease in his locality with a view to its control and removal. He shows the marked success which has followed the efforts of the State, through its municipalities, to reduce the mortality from almost every one of the great groups of disease which are responsible for the deaths of the people. After the registration system was introduced in 1837 the mortality remained almost stationary till the development of the public health legislation, to which we have referred, when the general mortality began to fall and has progressively fallen. In regard to every great group of disease this fall in mortality holds save in the dietetic group, which is subdivided into three headings—deaths from starvation, deaths from scurvy, and deaths from intemperance. Deaths from starvation have fallen from 18 to 12 per 1,000,000; deaths from scurvy, 1 in 1,000,000, have remained stationary; but with deaths from intemperance the case is quite otherwise—they have risen from 45 per 1,000,000 of those living in the year 1878 to 77 per 1,000,000 in 1897. Dr. CARTER is impatient with such a state of matters and calls for its redress by "legislative or other action." He shows how typhus fever, small-pox, and hydrophobia have been controlled almost to complete disappearance by the effective administration of the law. He maintains that law can do much to control and diminish death from alcohol. One fact with medical bearings he adduces. The magistrates of Liverpool, under the powers of an Act of 1872, determined to curtail the period of sale of alcoholic drinks by one hour on a Saturday night. Dr. CARTER made it his business to carefully collect from every dispensary and from the out-patient department of every hospital the number of cases of surgical injury due to drunken assaults on Saturday nights and Sunday mornings for a certain number of weeks before and after the curtailment of the hours. He has been enabled to show, without a single chance exception at a single institution, an extraordinary diminution since the curtailment of the hours of sale, a fact which not improbably influenced the magistrates to maintain the curtailment in spite of the great pressure that was put upon them to do the reverse. One such fact as this should dispose of most of the nonsense that we hear to the effect that legislation has done all it can to mitigate the preventable disease of alcoholism, which has increased and is increasing, and which keeps up the pauperism of the country in a time of unprecedented prosperity.

It is idle to think that any provision for confirmed drunkards will materially benefit either them or the nation unless efforts are made by the legislature and by society to prevent their being manufactured wholesale. We have shown that many leaders of the profession have viewed the question of our national habits with seriousness. The medical profession throughout the kingdom will be acting in the spirit of the true physician in refusing to be satisfied till legislation does for the mortality from alcoholism what it has done for the mortality from whole groups of other diseases which do not so fatally affect the people. We may appear in our columns of late to have somewhat laboured the temperance question, but we are sure that our readers will not confuse us with the well-meaning but over-zealous advocates of total abstinence. Although in every section and sub-section of human life there will be weaker vessels requiring protection for themselves of which stronger men feel no need, it is, in our view, ridiculous to desire to put men into leading strings because babies cannot walk. Yet no temperance lecturer can be more profoundly convinced than we are ourselves of the terrible mischief that is being

done to our country at the present day by our alcoholic indulgence. This view is, we are certain, shared by the medical profession of the kingdom whose position for using words of caution and remonstrance is unique and who have opportunities of studying the alcohol question at first hand which are denied to temperance lecturers.

Isolation Hospitals.

FOR some weeks past a discussion has been proceeding in our columns as to the value which is to be attached to isolation hospitals in relation to the control of scarlet fever. Those who are associated with these hospitals have not come forward with the alacrity which might have been expected, but possibly they are reserving their efforts for the discussions which, we believe, are very shortly to take place at the Society of Medical Officers of Health and at the Epidemiological Society of London. The subject is one of very great importance and the responsibility of those who endeavour to deal with the problem without a proper appreciation of all the factors involved is enormous. It is for this reason that we have determined to point out some of the issues at stake and some of the fallacies into which Mr. E. D. MARRIOTT of Nottingham, who has taken a prominent part in this controversy, has, in our view, fallen. Had he turned his attention in the direction of reform he would have found us on his side, but when he wishes to deprive the public of the advantages of isolation hospitals we feel constrained to examine his position closely.

In THE LANCET of Dec. 8th, 1900, p. 1661, we contrasted, in a leading article, the modern conception of an isolation hospital with that which obtained in olden days when the nature of infection was less perfectly understood. We referred, too, to a pamphlet written by Mr. MARRIOTT which aimed at condemning *in toto* such institutions owing to the fact that they had failed to "stamp out" scarlet fever. We challenged the writer of the pamphlet to refer us to even the most antiquated memorandum on isolation hospitals issued by the Local Government Board which might afford him some grounds for the "stamping-out" thesis, which he has apparently borrowed from certain enthusiasts of bygone years. In his reply, which we published in THE LANCET of Dec. 15th, 1900, p. 1759, Mr. MARRIOTT was silent upon this point; and, moreover, he apparently changed his ground from a general attack upon isolation hospitals to the more specific case of scarlet fever alone. Mr. MARRIOTT'S contention would appear to be this: that the risk of infection from invaded houses to the rest of the community is not, as we contended it was, lessened by the use of isolation hospitals but is actually increased, and this through the medium of "return" cases. We feel it difficult to take this expression of opinion seriously. Stated in other terms it means that the occurrence of the cases which at times result from patients discharged in an infective condition from a fever hospital more than counterbalances numerically the cases which might be considered as likely to arise were the original cases left in their own homes—in the one- or two-roomed, often overcrowded, dwellings of the poor—during the whole period, some eight weeks, of infectivity. The burden of proof is, of course, with Mr. MARRIOTT, but it may be asked whether a source of infection which is relatively uncontrolled for many weeks is not as likely to be harmful to the public as one which is at once removed to a well-conducted isolation hospital. It is surely admitted by all those who are familiar with hospital administration that a discharged patient may possibly be a source of infection, and hence at some hospitals the friends are warned that there is such risk; but to any well-balanced mind this is hardly a sufficient reason for condemning the whole system. Rather is it a reason for less concentration, and the adoption of such measures as have been found, at Manchester and elsewhere, very materially to reduce the number of "return" cases.

Mr. MARRIOTT will, we trust, forgive us if we question his entire comprehension of the epidemiological problems at issue, and if we ask whether he is not rather confusing notification with isolation. He shows by tables that in certain of our large towns the amount of isolation which has been at present practised has not led to any *demonstrable* decrease in the number of notified cases of scarlet fever and he at once infers that such institutions are worse than useless. But here he is endeavouring to establish a fixed standard for an ever-varying and uncertain quantity; he entirely overlooks the fact that, as pointed out by Dr. A. J. TONKIN in THE LANCET of Dec. 22nd, 1900, p. 1835, certain diseases have their periods of increase and decrease quite irrespectively of the influence of any sanitary measures, and that hence the diminution of such increases is all that can at present be hoped for, unless with a disease such as plague in Glasgow we can, as it were, get round the whole outbreak at once. A parallel might be pictured in the case of a town where, for some reason imperfectly understood, the number of fires increased year by year notwithstanding the fact that the fire-brigade service was yearly more complete. Mr. MARRIOTT would, it seems to us, disestablish the fire engines rather than seek to control the amount of inflammable material in the town. As regards the fall in the fatality-rate of scarlet fever which has undoubtedly taken place for many years past, Mr. MARRIOTT alleges that such fall received a check when isolation became *general*. It is difficult to ascertain when isolation did thus become general, and it is news to us that it is so at the present moment, but Mr. MARRIOTT assumes that it became general in or about 1893. In endeavouring to demonstrate this point he furnishes a table showing the average number of deaths from scarlet fever per 1,000,000 persons living in successive quinquennia from 1861 to 1893, his quinquennia, be it noted, ceasing with the period from 1886 to 1890 when the average was 241 per 1,000,000. For the year 1891 the rate per 1,000,000 was 171; for 1892, 190; and for 1893 it was 235. Here he stops, but we must point out that had he made use of the figures at his disposal—he refers to other rates even for 1899—he would have had to record 149 per 1,000,000 for 1895 and 113 per 1,000,000 for 1898, while for the period 1891–1895 the lowest quinquennial rate on record—i.e., only 182 per 1,000,000—was registered, and this with the increasing use of isolation hospitals. Vital statistics are, Mr. MARRIOTT observes, "the third degree of comparison of unveracity," and when used in this way and

applied to estimate the effects of any given measure upon a wave the initial magnitude of which is unknown and *unknowable*, they are apt to be ludicrously misleading. We leave our readers to determine to what degree we have been just.

We asked on Dec. 8th what Mr. MARRIOTT would do without isolation hospitals in the event of bubonic plague visiting England. Mr. MARRIOTT replies that Dr. J. F. PAYNE in his article on Plague in CLIFFORD ALLBUTT'S "System of Medicine" writes that "under some circumstances the patient might be better isolated in his own house." We quite agree with this; but Mr. MARRIOTT, had he given us the context necessary to convey Dr. PAYNE'S meaning, would have written: "The infected house should be emptied, patients should be removed to a hospital, and the other inmates isolated under observation." In his communication of Dec. 29th Mr. MARRIOTT raises questions as to the varying prevalence of scarlet fever and he apparently maintains that no such variations are recognised. If Mr. MARRIOTT will turn to the last edition of WHITELEGGE'S "Hygiene and Public Health," which is, perhaps, the most widely read text-book on the subject at the present time, he will find on page 288 these words in reference to scarlet fever: "In many districts it rises and falls with almost rhythmic regularity for long series of years, the usual interval between the epidemic maximum being five or six years. ..... In most towns epidemics occur at more or less irregular intervals." It had never "dawned upon me," Mr. MARRIOTT wrote, "that any man who had in view the objects aimed at by the establishment of isolation hospitals would build up an argument founded on the admission that no effort can stay the oncoming of the periodic wave. It is a kind of logic which I find extremely puzzling." Here Mr. MARRIOTT admits that he has not kept himself in touch with modern epidemiology. He will discover many references to this very point in the pages of THE LANCET, and if he will refer to the Public Health section of our last Annus Medicus he will be gratified at finding in regard to plague a candid admission of the position he finds so puzzling. With certain infectious diseases, as with certain foods, there are years of plenty and years of scarcity. What makes for the one or for the other is not as yet apparent, and in the meantime what we seek to bring about by notification and isolation is to reduce the magnitude of the upward wave and hasten the fall of the downward wave; in other words, we endeavour to mitigate or increase the *effects* of nature's laws.

Perforation in Typhoid Fever: The Indications for Surgical Operation.

PROFESSOR OSLER has made for himself such a commanding position among physicians that any article that bears his name is certain to attract wide notice from his professional colleagues. But we make no apology for drawing special attention to the short communication from him which is published in our columns to-day, for it deserves to be very widely read and pondered, not only by those to whom it is especially addressed—the resident officers of hospitals—but by all who undertake the medical care of patients having typhoid fever, and by all operating surgeons. A physician of wide experience and great knowledge like Dr. OSLER does not lightly speak or write on the treatment of typhoid fever; he knows how profound are the problems to be solved, and how great have been the labour, the knowledge, the skill, and the experience which have already been brought to bear upon their solution. Those whose experience is small, and knowledge perhaps less, are often found vaunting some specific for this, that, or the other feature of this terrible disease Not so the really learned. Dr. OSLER'S special point in his present article is the urgent need for the early recognition of intestinal perforation in the course of typhoid fever. He points out that 25 per cent. of the deaths in this disease are due to perforation of the bowel, and he alleges that in his wards from 30 to 40 per cent. of the cases of perforation have been rescued from death by timely operation. Such a statement from such a source is of the highest moment and it records a result that even the most sanguine did not anticipate when this treatment was first suggested and carried out.

To obtain success certain conditions appear to be necessary. In the first place, the occurrence of the perforation must be recognised *at once*, before the widespread peritonitis has abolished all hope of saving life. In the second place, the local condition must be capable of surgical treatment; extensive infiltration of the bowels or, still worse, considerable sloughing, appears to contra-indicate operation. These conditions cannot be accurately determined before operating, and the surgeon must therefore be prepared to find it impracticable to complete his operation in a certain number of cases. The third condition is such a physical state of the patient as will enable him to stand the strain of the operation. Upon this point it is necessary to remember that the shock of the operation has not proved so fatal as might have been expected, and some desperate cases have weathered the storm. Dr. OSLER himself mentions cases in which "the operation is successful, but the patient dies in the due course of the disease from the intensity of the fever or in a relapse." That is to say, there have been patients who were so desperately ill with the general effects of the fever that they ultimately succumbed to it, but who yet successfully passed through the operation for closure of the perforation. But even more striking than such is the case briefly mentioned by Dr. OSLER of a patient who twice over in an attack of typhoid fever was operated upon for intestinal perforation and on a third occasion had the abdomen opened on the supposition that another perforation had occurred. That any patient in the later weeks of typhoid fever can survive three successive abdominal sections is a proof that the chance of life afforded by operation must not be lightly denied because of the "shock" or other constitutional strain which it will cause. The fourth condition of success is rapid and careful operating. A general anæsthetic can often be dispensed with, injection of eucain with perhaps just a whiff of chloroform being sufficient to prevent pain. Great manipulation of the bowel must be avoided and all procedures should be rapid and careful. In the best cases suture of the bowel so managed as to fold in the edges of the perforation is the proper procedure; in

a small number of the cases the bowel is too extensively diseased to admit of this and an enterectomy must be effected. The operator must be prepared for either course and must make up his mind promptly.

Of all these conditions the time between the perforation and the operation is the most important. When general peritonitis is well established operative treatment is practically quite hopeless. The problem is how to recognise and deal with the perforation directly after its occurrence without waiting. For this to be possible the diagnosis must be made quite early, and it is to this point that the attention of our readers is specially attracted. A sudden severe pain in the abdomen is the most constant sign, but perforation is not the only cause of such pain. A distinct change in the condition of the abdomen—rigidity, immobility during respiration, fulness, a markedly tympanitic area, or the abolition of liver dulness are all points to be carefully investigated. A sudden fall of temperature or rise in the pulse-rate is also significant. It is not by relying upon any one of these signs, however, that a diagnosis will be arrived at, but rather by the ability to appreciate that a sudden change in the local and general condition has taken place. If diagnosis is postponed until the abdomen is distended and motionless and the patient profoundly collapsed, the time for successful surgical aid will have passed by. Too much stress cannot be laid upon the urgent importance and great difficulty of early diagnosis. It will only be achieved by those in attendance keeping a very careful watch upon all the local and general symptoms The problem presents itself in many forms in medicine and surgery. In penetrating wounds and contusions of the abdomen it is often extremely difficult to determine whether perforation of the bowel has occurred or not. How often, too, are the symptoms of a perforated appendix most ambiguous, and the golden opportunity for surgical treatment is lost! We feel sure that Dr. OSLER'S appeal for a more minute and careful observation and record of all such cases will be generally welcomed, and we hope that it will be attended with great success.

Annotations.

"Ne quid nimis."

THE ROYAL COMMISSION ON THE BEER-POISONING EPIDEMIC.

THE Royal Commission which was appointed to inquire into the "recent exceptional sickness and death attributable to poisoning by arsenic in beer" met for the first time on Feb. 5th, under the presidency of Lord Kelvin, to consider the course of procedure. We believe that a preliminary course of procedure was decided upon, and we hope that the Commissioners have elected to direct their attention in the first instance exclusively to the question of poisonous beer. As we have pointed out, "exceptional sickness and death" have been traced indubitably to arsenic in beer, and this matter needs no further discussion. We hope the Commissioners will at once decide upon a recommendation that legislative measures be immediately taken to stop effectually the introduction of arsenic into beer. The consideration of the "pure beer" question is quite secondary to this, although we must admit that in view of recent disclosures this question may well be re-opened. Further, it seems to us that the terms of reference are so wide as practically to fix upon the Commissioners the responsibility of deciding the question as to what steps should be taken to secure the absolute freedom from arsenic of all food products, and what limitations in regard to the quantity of arsenic should be laid down in other products, in fabrics, for example, carpets, dress materials, wall-papers, and so on. The epidemic following upon beer-poisoning has opened an enormous field for inquiry, and we doubt not that much valuable evidence will be given before the Commission on the whole general question of the possibility of arsenic occurring, from a just traceable quantity up to an estimable amount, in food and food products and other articles of every-day use. It is no longer a Royal Commission on beer-poisoning; it is a Royal Commission to inquire into the presence of arsenic in countless directions. We maintain that so far as the inquiry relates to beer-poisoning the materials are already to hand which should enable legislation to be soon set afoot in the form of a short Bill to suppress the possibility of arsenic occurring in beer; and in view of the deaths and sickness that have been caused we consider that a remedy more rapid than a Royal Commission might have been found. The question of the presence of arsenic in other food materials must needs involve a prolonged inquiry, but there is here no pressing necessity, as in the case of the beer-poisoning epidemic, for immediate legislative measures. Clearly, if the Royal Commission decide to conduct an investigation into the possible presence of arsenic in, we had almost said, everything, we may have to wait a very long time before any definite measures are adopted effectually to stop the introduction of arsenic into beer.

THE PHARMACOPŒIA AS A LEGAL STANDARD.

IN commenting upon a case in our issue of Jan. 19th which related to the sale of mercurial ointment considerably below the strength of the formula laid down in the British Pharmacopœia, we remarked that there is a good deal to be said in favour of the view that where a thing is not sold in accordance with the standard of the British Pharmacopœia it ought to be so labeled. This is exactly the view since presented in the judgment given in a precisely similar case in the King's Bench Division of the High Court. Here, again, the drug sold was mercurial ointment which proved to contain 12·5 per cent. of mercury instead of 48·5 per cent. as laid down by the British Pharmacopœia. The case had been stated by the magistrates sitting at Skipton in Yorkshire, and it raised the question of whether the decision of the magistrates upon an information under the Sale of Food and Drugs Act, 1875, was correct. It was contended that the ointment supplied not being in accordance with the standard of the British Pharmacopœia was not of the nature, substance, and quality demanded within the meaning of the statute. The appeal was dismissed, for their lordships (Bruce and Phillimore) held that as the appellant was asked for mercurial ointment he should have sold the drug as prescribed in the British Pharmacopœia; or if he was going to sell ointment in which the mercury was only about a quarter of the standard strength, which he in fact did, he should, if he sold such a drug at all, have explained that he was selling a weaker or diluted drug and have so named it. Their lordships further pointed out that what the appellant did attempt to prove was that there were two commercial standards of wide difference, "a thing in itself unreasonable, while he said he kept both standards in his shop and sold one standard or the other

according as customers did or did not bring a prescription from a medical man. He might almost as well keep two weights or two measures." They were of opinion, therefore, that the cases which they had quoted established the fact that if a drug was to be found in the British Pharmacopœia, and that drug was asked for, that drug must be supplied, and if it was not sold with the ingredients in the proportions prescribed by the British Pharmacopœia there was at least *prima facie* evidence that what was sold was not of the nature, substance, and quality demanded. This ruling seems to us clearly to regard the British Pharmacopœia as a definite legal standard for drugs, and thus to settle the contention that has been going on for some time as to whether it was legal to refer the strength or standardisation of drugs to the British Pharmacopœia under the Sale of Food and Drugs Act. Many pharmacists hold that it is, while some analysts think that it is not. This important decision of the High Court practically regards the British Pharmacopœia as an authority on the standard and strength of drugs.

THE DEATH FROM PLAGUE IN CONSTANTINOPLE.

ON Jan. 7th a death from plague occurred in the Clinical Hospital attached to the School of Medicine in Stamboul. The patient, as has already been recorded in our columns, was *caïkjee*, or boatman, to a custom-house official who lives at Beicos, on the Asiatic side of the Bosphorus, some 12 miles from Constantinople itself. The man fell ill about 15 days before his death; he was seen by a medical man at Beicos, who diagnosed the case as one of influenza complicated with pneumonia. Influenza, it may be stated, was at that time seriously epidemic in this city and its neighbourhood. As he became worse his brother was telegraphed for and on Jan. 4th the latter removed the patient to Selimieh, a suburb of Scutari—the town which faces Constantinople on the Asiatic side of the Bosphorus. Here he lay for three days and nights, occupying a room over a café frequented by boatmen. On Monday, Jan. 7th, he was rowed across in a *caïk* to Stamboul and carried up to the Clinical Hospital. He died almost immediately after being admitted. The nature of the case had not been recognised by the hospital authorities before death, but by a fortunate chance the patient had been seen during the course of his removal from Scutari to Stamboul by a physician who had some experience of plague. The latter at once recognised the nature of the case and reported it to the municipality, who were enabled to take action before the body was buried. Professor Nicolle, the director of the Bacteriological Institute of Constantinople, was summoned. He found a bubo in one groin of the cadaver and the bubo contained an enormous quantity of bacilli, which possessed all the morphological and cultural characters of plague bacilli. The cultures when inoculated into rabbits caused death in 48 hours. Whence the infection came in this case has not been proved, but it is more than possible that the case was in some way connected with the recent recrudescence of plague in Smyrna. The man had friends in Smyrna and had visited that town some three months before his death. It is possible that he had received letters or parcels from Smyrna which had in some way conveyed the infection to him. For the measures taken in and around Constantinople in consequence of this death the municipality was mainly responsible. The Ottoman Board of Health was in a position only to give advice and to make suggestions, but as the highest sanitary authority in the country its advice was asked for, given, and acted upon. Two special meetings of the Board were held on Jan. 9th and Jan. 11th, and a number of measures tending to allay panic, and particularly to ensure that the authorities should have early knowledge of suspicious cases or of any unusual phenomena in the rat world, were suggested and carried out. A small committee of four medical men, two nominated by the Sultan and two by the Board, was formed, to hold itself in readiness to investigate any doubtful case of disease or death, whether in man or among rats. Fortunately their services have not been required, as nothing has occurred since Jan. 7th to raise the suspicion that the infection of plague still exists in or near Constantinople. The only quarantine measure imposed by the Board of Health upon shipping was a medical visit with disinfection on arrivals from Constantinople in other Turkish ports. The neighbouring countries were stricter, and Russia, Roumania, Bulgaria, Greece, and Egypt all imposed a quarantine of 10 days upon arrivals from Constantinople. As this action on the part of Russia was a direct infringement of the Venice Convention which was accepted by that country attention has been drawn in the proper quarter to this—the second occasion within four months on which Russia has broken the convention. At the moment of writing all quarantine measures in other countries against Constantinople have been withdrawn.

THE ROUTE AT THE QUEEN'S FUNERAL.

IT speaks well for the arrangements that were made on Saturday last, Feb. 2nd, to keep the route for the passage of the Queen's funeral *cortège*, that although vast crowds assembled in the metropolis to pay their last sad and solemn homage to the memory of a dearly beloved ruler, few accidents occurred that were of a serious nature. Deep love and high respect for Queen Victoria undoubtedly played no little part in the order which prevailed. Hooliganism was absent, for its exemplars, being no fools, felt that anything in the nature of rowdyism would have met with a hostile reception on the part of all men. The most serious accident which has come to our notice happened to a police-constable who was kicked in the lumbar region by a troop-horse. The man was taken to St. Mary's Hospital and is now progressing favourably. A man was kicked severely in the abdomen by a troop-horse in Edgware-road, of whose fate we have had no news. Some 30 cases of faintness and fits were also treated at St. Mary's Hospital, while at St. George's Hospital there were several cases of simple fracture. At Westminster Hospital a few cases of fainting were treated. Some two dozen of the injuries treated were the result of falling from trees, eight of the sufferers being females. The medical arrangements along the line of route were in charge of Surgeon-Lieutenant-Colonel J. E. Squire, V.M.S.C., who was assisted by Surgeon-Major Matthews, V.M.S.C., and Captain L. Way, R.A.M.C., together with about 20 officers and 400 men of the Volunteer Medical Staff Corps.

SCALDS OF THE PHARYNX AND LARYNX.

IN the *Deutsche Medicinische Wochenschrift* of Jan. 31st Dr. E. Schmidt of Britz reports a case in which a boy, three years of age, attempted to drink from the spout of a tea-kettle full of boiling water. The parents were unable to say whether any of the water had been swallowed or whether the symptoms were due to the steam alone. When the immediate pain and terror had subsided the child was able to drink without apparent suffering, and the parents were hopeful that no harm had been done, but during the night difficulty of breathing set in and the child was admitted into hospital next day. There were then hardly any perceptible signs of injury, as the lips, tongue, and pharynx were perfectly normal, and there was nowhere any marked redness of the mucous membrane, but there were dyspnœa with rapid breathing and some pain in swallowing. Laryngoscopic examination was impossible on

account of the child's restlessness. In the afternoon there was a change for the worse, and subcutaneous emphysema starting from the throat spread to the body, neck, and cheeks. Tracheotomy was performed in the evening. The child died next day from cardiac debility and pneumonia. The interest of Dr. Schmidt's article consists not in the clinical phenomena but in his statement that such an accident is hardly known in any country except England. In Germany, he says, such an occurrence is never met with, or at least is excessively rare. Four cases which have been recorded in German literature—namely, in the *Journal für Kinderkrankheiten* for 1860 and 1867—relate to children into whose mouths hot fluid was poured as they were lying down. On the other hand, in England, in St. Thomas's Hospital alone from 1872 to 1893 there were 78 cases. Dr. Schmidt attributes these accidents to the universal practice of drinking tea among all classes in England and quotes from Mackenzie on "Diseases of the Larynx" to the effect that children are commonly allowed to drink from the spout of the teapot and they afterwards, not understanding the danger, attempt to do the same with the tea-kettle.

ASTHENIC BULBAR PARALYSIS AND ITS PATHOLOGY.

Professor J. Déjerine and Dr. R. Thomas have published in the *Revue Neurologique* of Jan. 15th last a valuable communication on the subject of asthenic bulbar paralysis, which gives, apparently for the first time, some definite account of the pathology of an affection which hitherto [1] had been supposed to be a disease without discoverable morbid changes in the cerebral nervous system. The first clinical description of the disease was published by Wilks in the Guy's Hospital Reports for 1877 and in the following year Erb of Heidelberg gave a detailed description of a case. A few cases have been described clinically since then and the results of necropsies made by Oppenheim, Strümpell, Jolly, and Sinkler have hitherto given negative results. Widal and Marinesco mention briefly that chromatolytic changes were met with in the bulbar nuclei of the cranial nerves in one case examined by them, but state nothing regarding the cerebral cortex, pyramidal tracts, or muscles. Glockner reports similar changes in the dorsal nucleus of the vagus nerve in one case, while the other cranial nerve nuclei showed no changes. He also records a fatty degeneration in the muscles of the tongue. The case recorded by Professor Déjerine and Dr. Thomas is as follows. A woman, aged 58 years, of good heredity, married, had repeatedly suffered from headache and vertigo since the menopause. Hearing was subsequently dulled in both ears and speech was slightly embarrassed. On admission to hospital there was some trouble in swallowing, and she suffered also from dental neuralgia. There was slight right sided facial paralysis and speech was nasal in tone. Laryngoscopic examination showed a paresis of the adductors of the vocal cords. Her mental condition was normal and the cutaneous and deep reflexes were retained. She frequently suffered from marked somnolence. She now grew progressively weaker, was unable to masticate or to swallow food, the reflexes of all four limbs grew exaggerated, and she died from an intercurrent attack of pneumonia after having been in hospital nearly two years. At the necropsy the nervous system (cerebrum, spinal cord, meninges, and cranial nerves) appeared normal to the naked eye. Histological examination, however, revealed the following changes. The cerebral cortex, the ascending frontal convolution, showed irregularly distributed changes—viz., a very marked multiplication of neuroglia cells and a considerable diminution or rarefaction of nerve cells. The neuroglia overgrowth was particularly conspicuous in the molecular layer and consisted of irregularly stellate and rounded cells. The apical expansions and protoplasmic terminals of the cortical cells had disappeared and the cell-bodies when they still persisted were reduced to rounded masses or to nuclei clothed with a thin layer of protoplasm. The capillaries were numerous but their coats were unaltered, and the large blood-vessels also appeared normal and free from appearances suggesting inflammatory reaction. In intervening cortical areas relatively intact nerve-cells were present. The nerve-fibres both of the tangential and projection systems appeared normal. No lesions could be found in the internal capsules or basal ganglia. The bulbo-spinal nuclei appeared quite normal. The muscles of the tongue and larynx showed fatty degeneration and the nerves supplying these were similarly affected. Scattered degenerations were found among the pyramidal nerve-fibres in their course through the bulb. While definite lesions were thus met with the cause remains yet obscure.

[1] Sinkler: THE LANCET, Oct. 21st, 1899, p. 1110.

WOOD-SPIRIT IN WINES AND SPIRITS.

IT would appear that methyl-alcohol, the chief alcohol of wood-spirit—so-called because it occurs in the products of the distillation of wood—is produced during the process of fermentation of fruit sugars. Accordingly, by means of a beautiful and delicate test, wood-spirit has been found in important though small quantity in wines and in the spirit distilled from wine—namely, brandy. This observation may be of the utmost importance in aiding the discrimination by chemical means of genuine grape-derived spirit from that distilled from grain. Odd as it may seem, methyl-alcohol is not found in spirit obtained by the fermentation of cane sugar, nor can it be traced in any grain spirit, as in whisky or in rum, or in commercial spirits of wine. Brandies, however, even of the low grade kind and obtained from partially spent grapes or marc, gave distinct evidence of the presence of methyl-alcohol. It is premature to state positively that this test will furnish a means of distinguishing absolutely genuine from "fabricated" wines, or grain spirit from grape spirit, but it is to be hoped that this line of investigation will be further pursued. Suffice it to say that the test which has been regarded to identify the wood-spirit is based upon the action of resorcin on formaldehyde which is produced by oxidising the methyl-alcohol in a special manner. It is interesting to add that there is no reason to believe that pure and matured methyl-alcohol is more injurious than ethyl-alcohol. The amount, at any rate, in wines or spirits must be small.

THE INVESTIGATION AT BELLEVUE HOSPITAL. NEW YORK CITY.

THE investigation which has been undertaken at Bellevue Hospital owing to the charges made against its management has revealed the following facts. During the year 1900 24 307 patients were treated in Bellevue. Of these patients 1720 died, or about 7 per cent. of the entire number treated. This percentage really indicated a larger death-rate than ordinarily could be charged against the hospital since it receives a large number of patients from other hospitals in a moribund condition upon their arrival. The daily census of Bellevue for the year 1899 shows that the average number of patients under treatment was 690 per day. In the year 1900 the average number of patients treated per day was 733. In the year 1899 4081 patients were treated in the alcoholic ward; in the year 1900 3753 patients were treated in this ward. In the male alcoholic ward in 1899 there were 146 deaths; in 1900 there were 160 deaths. The total number of deaths in the female alcoholic ward for these two years was 81, 46 in 1899 and 35 in 1900. The deaths in the male alcoholic ward in 1899 amounted to 3·5 per cent. of the

number of patients treated; in 1900 it was 4·26 per cent. The number of deaths in the female alcoholic ward for the year 1899 was 2·75 per cent. of the patients treated; for 1900 it was 2·41 per cent. In 1899, 1218 patients were admitted to the pavilion for the male insane; of these patients 29 died. To this same ward in 1900 there were admitted 1265 patients, while the number of deaths was 40. The number admitted to the pavilion for the female insane in 1899 was 1049, of which number 17 died, making the death-rate 1·62 per cent. In 1900, 1160 patients were treated n this ward and 32 died, making the death-rate 2·76 per cent. Those responsible for the management of the institution claim that it has been conducted well and that the records of the wards compare favourably with those of any hospital in the city. The figures certainly bear out this claim, but we trust that the investigation will be thorough.

THE SANITARY INSTITUTE.

AT a special meeting of the Council of the Sanitary Institute, Earl Fortescue, Vice-President, in the chair, an address to the King, and signed by H.R.H. the Duke of Cambridge as President, on the death of Her Majesty Queen Victoria was adopted, in which the following words occur:—

"Among the many noble attributes that endeared the Queen to the hearts of her people none was more potent than her widespread sympathy with all classes of her subjects, and in no branch was this more markedly shown during her long reign than in the interest which our late beloved Queen and several members of her Royal house specially showed in the adoption and development of measures for the improvement of the health of the people, and of the conditions under which they, and especially the poorer classes of them, live."

All the medical profession will echo the sentiment thus expressed.

"THE LOGIC OF A CORONER."

WITH reference to an annotation under the above heading which appeared in our issue of Jan. 12th, p. 118, we see that Mr. P. J. O'Keefe wrote to the Registrar-General upon the question of the inclusion of the fracture of the leg as a secondary cause of death in the case of Mary Anne Teresa Ronchetti. The Registrar-General replied, "As you ask for my opinion I may say that your certificate appears to be quite in order and to be in accordance with the instructions issued from this office." This is what we should have expected. Another point of interest came up before the same coroner at an inquest held at Crosby on Jan. 7th to inquire into the death of Mary Jane Woosey, aged 75 years, who died on Jan. 3rd. Deceased had fallen downstairs on Nov. 30th, 1900, and Dr. W. G. Little, who was called in, attended her up to the time of her death. After death he refused to give a certificate and apparently—for the newspaper report supplied to us is not very clear—the case was reported to the coroner who sent his officer or the police to obtain information as to the cause of death from Dr. Little. This information Dr. Little refused to give except, as he stated to the coroner in a letter, "upon summons in a regularly constituted court and upon oath." At the inquest the coroner is reported as saying that Dr. Little was bound to give a certificate. Another passage of the report runs as follows: "In reply to the inspector the coroner said he was perfectly justified in sending his men to medical practitioners to collect information for this court. If the doctors refused the information then all that the inspector had to do was to report it to him and he would know how to deal with the matter." Dr. Little's argument was that as death had occurred within six weeks of the accident he could not give a certificate. The length of time has, of course, nothing to do directly with the question of whether a certificate should or should not be given. But the chief point at issue seems to us to be whether in case of a doubtful death a medical man is justified in giving evidence, naturally not on oath, to a policeman concerning the cause of death. The coroner was of opinion that the medical man was not justified in refusing to do so. The Coroners Act simply states that "When a coroner is informed that the dead body of a person is lying within his jurisdiction and there is reasonable cause to suspect that such person has died either a violent or an unnatural death ..... the coroner ..... shall as soon as practicable issue his warrant for summoning ..... good and lawful men ..... to inquire as jurors touching the death of such person as aforesaid." It is quite clear from this that the coroner must have some information to go upon. But it is equally clear that medical evidence ought to be given directly and upon oath by a medical man, and not be admitted second-hand through the medium of a policeman or a coroner's officer, who cannot know what is the essential part of the testimony he is giving and who is liable to make lamentable omissions or additions and no less lamentable deductions.

ORGANO-THERAPEUTICS IN MENTAL DISEASE.

DR. C. C. EASTERBROOK of the Royal Asylum, Morningside, Edinburgh, has published a valuable contribution to our knowledge of organo-therapeutics in mental disease. He points out that the "immediate nutrition of any organ is of a two-fold nature, hæmic and nervous, and depends upon a proper supply of blood pabulum and of trophic nerve impulses." The brain cortex directly dominates the nutrition of the efferent portion of the central nervous system and thereby it indirectly controls the nutrition of the bodily organs. Hence from prolonged worry or mental strain (cortical nervous disturbance) will follow a furred tongue, anorexia, constipation, and palpitation (peripheral bodily disturbances of nutrition), and the patient will run down in physical condition. Since the discovery of Brown-Séquard of "internal secretions," and of G. R. Murray and Victor Horsley of the specific action of the thyroid extract in myxœdema many therapeutic attempts have been made in the direction of organo-therapeutics, and in recent years this treatment has been extended to mental diseases. A summary of Dr. Easterbrook's results has already appeared in THE LANCET,[1] in the Proceedings of the Section of Pyschology at the meeting of the British Medical Association at Ipswich, 1900. The results of treatment vary according to the published statistics of various writers. Mabon and Babcock have given a summary of over 1000 cases collected from literature and from unpublished cases in American asylums. Collectively the cases amount to 1032, of which 16·8 per cent. are reported as recovered, 24 per cent. as improved, and 59·2 per cent. as unimproved. Dr. Easterbrook states that "many of the recoveries reported were not true tests in that thyroid was employed when there was still a good chance of recovery by the ordinary methods of treatment." In Dr. Easterbrook's series of 130 cases of insanity treated with thyroid extract all the patients were suffering from insanity which at the time was stationary or chronic or regarded as incurable. The results were, on the whole, not favourable. Amongst the symptoms noticed to follow were loss of weight, increased bodily metabolism, quickening of the pulse, phosphaturia, and general cerebral stimulation. The results with women were more striking as regards recovery than with men, and it is concluded that "the thyroid treatment of insanity is more efficacious in women than in men," this being perhaps owing to the fact

[1] THE LANCET, August 25th, 1900, p. 610.

that the thyroid gland is functionally more active in women than in men and that it enlarges during menstruation and pregnancy. The best all-round results were obtained in the insanities connected with child-bearing. In *folie circulaire* the thyroid treatment was found to be useful in aborting the maniacal attacks. As regards the *modus operandi* of the drug it is thought that thyroid probably acts by freely stimulating metabolism and ridding the economy of transition and toxic products. Other substances—e.g., thymus, ovarian extract, orchitic extract, and the like—have similar effects, but the thyroid substance surpasses them in these respects.

CHILDREN IN THE REIGN OF QUEEN VICTORIA.

NOT last among those who honour the memory of our late beloved Queen should be the place of her children subjects. Her long reign was rich in measures devised for their welfare and protection. Until it began practically nothing had been attempted for their good. Trade practice was harsh and unscrupulous without restraint, and public opinion was ignorant or indifferent. Even the law was blindly callous in its rigour, so that we are amazed to find terrible penalties recorded against the petty thefts of mere children. Every measure on the statute-book which is intended to protect the rights of children has come into being within the Victorian era. Factory children, children employed in mines, in brickfields, in chimneys, in agricultural gangs, on canals, on the high seas, pauper children, street beggars and hawkers, acrobats, children in pantomimes, criminal children, all found in their Queen a friend as ready as powerful to help them. The last great act of this series and the crown of her endeavours on behalf of suffering childhood was the comprehensive measure passed in 1889. It grappled with two evils—cruelty practised upon children under whatever conditions, and the corruption of their morals. So great an assault upon the enemies of childhood might well succeed the process of sap and mine by which the same foes had been steadily weakened during 50 years. Its success has been its justification, though not its only one. There are proofs to show that the operation of this Act has accomplished much not only for the welfare of children but for the reformation and happiness of their parents also. It has brought into the dreamy indefinite ethics of the late nineteenth century something of "grit" and practical resolution. The national foot has gone down on abuses in our very homes because they were scandalous abuses which no so-called "liberty of the subject" could excuse. Would that we had more of this righteous determination in dealing with other strongholds of evil practice. With time, and light, and honest minds we are not without hope of further great results. For what we have recorded a liberal share of thanks must be assigned to a Sovereign who all her lifetime strove to do her duty to her country and to her kind.

IMMUNITY AND PROTECTIVE INOCULATION.

IN an address delivered at the annual meeting of the Texas Academy of Science Dr. H. W. Harper gave an interesting account of the various steps which had led up to our present knowledge of immunity and protective inoculation. He recapitulated the facts which led Jenner to his discovery of vaccination against small-pox, and then proceeded to discuss the parallelism which subsists between the phenomena of fermentation, infection, and immunity. His expositions on the chemical facts which have been ascertained as regards the nature of fermentation were very instructive, as also were his remarks on the chemical structure of certain ptomaines and leucomaines. The formulæ given in the address are too complicated to reproduce here. He next referred to the discovery of substances in the blood serum of animals immunised against diphtheria and tetanus which are able specifically to protect other animals against the toxins of these diseases—substances now known as antitoxins—and maintained that it has been shown by different observers that toxins were rendered innocuous by means of antitoxins through a purely chemical process in which biological processes had no share. Dr. Harper then went on to argue that the theories advanced by Pasteur, Metchnikoff, and others are insufficient to explain actual facts. He considered that the existing known conditions of immunity might roughly be divided into two groups—biological and chemical—and the explanations of their occurrence must follow this grouping and must be based on biological and chemical grounds. He believed that in the ultimate analysis the biological explanation will rapidly pass from the body as a whole to its respective organs and their respective cells to the nucleated cells and finally to the origin of the nucleus. His concluding remarks are a little difficult to follow. It is evident that he considers the problem of immunity to be a bio-chemical one, but long and patient investigation will be necessary before the chemical changes taking place between the toxins and antitoxins are fully understood and before the relative importance of the biological and chemical processes can be completely estimated.

UNNECESSARY RISKS IN WAR.

A COMPANY commander serving with his regiment at the seat of war and writing from the Transvaal sends a well-considered and common-sense communication to the *Times* of Feb. 2nd in which he refers to the carrying away of wounded men from the fighting line and the unnecessary risk of life to which this practice frequently gives rise. He is careful, of course, to guard himself against being understood to urge that wounded men should be left to take care of themselves, but he points out how frequently it happens that the natural desire to get a wounded man out of action may not turn out to be the best and most desirable thing to do for the man himself and how it may expose those who do so, or attempt to do so, to unnecessary risk. As far as the wounded man is concerned the movement—as in the case of wounds of the trunk of the body—may be actually injurious to him and in some instances take him further away from skilled surgical aid, for, according to the experience of the company commander, "he is more likely to find a doctor in the fighting line than behind it." Many instances are also cited in which those carrying away wounded soldiers from positions where they might have fared well have attracted the enemy's fire and been killed or wounded. He believes that in the aggregate the casualties occasioned in this way are considerable. "I am, I trust," he writes, "as humane as most people, but also somewhat utilitarian (we are not very utilitarian in the British Army as a rule), and on one occasion, knowing that we were going in for a stiff fight, I warned my company that we were not going in as stretcher-bearers, but to fight, and that no man was to leave his duty for the purpose of carrying away me or any other wounded man. We would want every available rifle in the firing line, for we were going in, I said, to win if we could (we did as it happened); when that business was concluded those of us who might be wounded could be seen to. I have heard of others giving the same order." We consider the company commander to be perfectly right. In every big engagement these attempts to rescue and remove wounded men occur as a matter of natural impulse and are usually prompted by the noblest motives, although this may not be invariably the case. But such attempts are not and, under the circumstances, cannot be

expected to be, well-considered beforehand, nor are they always in the best interest of the wounded themselves. The difficulty, however, is to lay down any rules of guidance or line of action to be followed. All that can be said is that each action must be decided upon on its merits and after a rapid survey of the situation. In ordinary European warfare the present bearer column system is probably the best, not only for systematically stripping a battle-field of its wounded, but for preventing any men from falling out from the fighting line under the pretext of helping a wounded comrade. In the case of South Africa, however, the conditions are either very or altogether different from those of European wars. There is sometimes one slender satisfaction in hearing of wounded men having been left for hours upon the battle-field. It is that in certain cases—those of abdominal wounds, for example—the absence of all movement, and the deprivation of fluid nourishment for the time being, offer the best chances of recovery, because the best obtainable state of physiological rest during the earliest stages of reparative process is thus secured.

TYPHUS FEVER IN MANCHESTER.

TYPHUS fever, a disease which arises principally under circumstances of filth, overcrowding, and destitution, is, owing to improved sanitary conditions, yearly becoming more rare in Great Britain, the last recorded outbreak being that at Sheffield in 1890. The *Manchester Evening News* of Feb. 4th states that, according to a report by Dr. James Niven, a somewhat serious outbreak exists in Manchester. On Dec. 31st, 1900, two young women were admitted into Ancoats Hospital suffering from enteric fever. On Jan. 5th, 1901, two other girls were admitted, the one suffering from enteric fever and the other from typhus fever. On Jan. 8th two more girls, both suffering from typhus fever, were admitted. All these girls had worked at the same place of business as sorters of small rags. It contained two rooms, the one set apart for the sorting of woollen rags and the other for the sorting of cotton rags. All the patients attacked were employed in the woollen rag room—namely, seven in all. The office-boy was also attacked and up to the date of Dr. Niven's report three persons had died. All the girls came from very poor homes, but careful investigation has hitherto been unable to account for the source of the disease. One patient, who lives in I—— street, Ancoats, apparently infected seven other persons, and on Jan. 22nd Dr. Niven and Dr. H. Coates visited her home, but were unable to get in. Entrance was accordingly forcibly effected and the father and two children were found in bed all suffering from typhus fever and too ill to do anything. In addition the mother had already caught the disease, as had also a woman who nursed her, while two children living next door but one to the house were removed to the hospital.

THE FOOD AND DRUGS ACT IN MANCHESTER

ACCORDING to the report of the public analyst appointed for the city of Manchester the total number of samples analysed during the quarter ending Dec. 31st, 1900, was 432, out of which 52 proved to be adulterated. Amongst the noteworthy adulterations was that of spirits to an extent which was at first unaccountably uniform. It subsequently appeared that in two cases this uniformity of water dilution was due to the use of a defective instrument by the publican when reducing his spirits to a certain strength with water. More interest, however, attaches to the report on this occasion on account of the results given of the analyses of a number of samples of arsenical beer. Apart from the arsenic the percentage of adulterated samples was quite low. It is, of course, now well known that the arsenic was due to impure glucose. But Mr. Estcourt points out that besides the firm already publicly incriminated, so far there are at least two other manufacturers, according to his information, who have delivered glucose contaminated with arsenic to brewers in other parts of Lancashire. In regard to the small quantities of arsenic found in beer (ranging from one-tenth to one two-hundredth of a grain of arsenious acid per gallon) he is inclined to think that this may be due to the malt used. Subsequently he found malt on the market used by some brewers which, apart from glucose altogether, would pollute the beer to the extent of one-tenth of a grain of arsenious acid per gallon. This contamination of malt is traced to the fumes arising from fuel containing arsenic used in the drying process. Thus a beer brewed from malt and hops exclusively will not necessarily be pure. As we have said before, the provisions of the Food and Drugs Act seem sufficient to insure the sale of beer free from arsenic and other contaminations. If the Acts are carefully put into force and public analysts will keep a sharp look-out for possible impurities careless brewers will have to mend their ways.

THE following appointments have recently been made at the Jenner Institute of Preventive Medicine. Dr. S. G. Hedin, of the University of Lund, Sweden, has been appointed head of the department of pathological chemistry; Mr. J. Beresford Leathes, Lecturer in Physiology at St. Thomas's Hospital Medical School, assistant in the same department; and Mr. W. J. Young, of Owens College, Manchester, assistant in the chemical department. Dr. A. Moore, Dr. G. Petrie, and Dr. A. McKenzie have been elected to fill the three research studentships, the last-named gentleman being appointed to the Grocers' Company Research Studentship of the Jenner Institute.

THE death is announced, at the age of 70 years, of Mr. John Cordy Jeaffreson. Mr. Jeaffreson was the son of a medical man, the late William Jeaffreson, F.R.C.S., and was married to the daughter of another medical man, Mr. William Eccles, F.R.C.S. Himself a barrister he never practised but devoted himself to writing and to historical research. He was an expert in ancient handwriting and worked under the Commissioners on Historical Documents. Among his best known works were a novel entitled, "Not Dead Yet," and "A Book about Doctors."

A MEETING of the Liverpool School of Tropical Medicine will be held in the Town-hall, Liverpool, on Tuesday next, Feb. 12th, at 2 o'clock P.M., to consider the subject of Health and Sanitation in West Africa and the Tropics, in the light of the researches of the three malaria expeditions of the school. The meeting will be addressed by Sir William Church, Bart., President of the Royal College of Physicians of London, and others. The chair will be taken by the Lord Mayor of Liverpool.

THE governors of the Italian Hospital, Queen-square, W.C., have forwarded the following resolution to His Majesty the King: "That the governors and staff of the Italian Hospital desire to record their profound sorrow at the death of Her Most Gracious Majesty the Queen, and to humbly tender their condolence to His Majesty the King and the Royal Family on the loss of one beloved by the world and whose memory will be revered in many lands."

THE Festival Dinner of the Royal Medical Benevolent College, which was fixed for Tuesday, April 16th, has been adjourned until Tuesday, July 9th. The chair will be taken by the Earl of Rosebery, K.G., the President of the College. Any friends of the institution desiring to act as stewards or wishing to be present on that occasion should intimate their

wishes to the Secretary, at the office of the College, 37, Soho-square, W.

THE Hunterian Oration of the Hunterian Society will be delivered by Mr. John Poland on Feb. 13th, at 8.30 P.M., in the London Institution. The subject will be: "A Retrospect of Surgery during the Past Century." The annual dinner of the society has been postponed to March 15th.

AT a meeting of the British Balneological and Climatological Society, held on Wednesday, Jan. 30th, the President, Dr. Bagshawe (St. Leonards), referred to the death of the late Queen Victoria, and moved an address of sympathy with His Majesty King Edward VII. which was unanimously passed.

MANY members of our profession, and especially members of the Edinburgh University Club, will be very sorry to learn of the death of Dr. Leslie Ogilvie, which took place on Saturday evening, Feb. 2nd. We hope next week to publish an obituary notice.

REFLECTIONS ON THERAPEUTICS.

BY HARRY CAMPBELL, M.D., B.S., F.R.C.P. LOND.,
PHYSICIAN TO THE NORTH-WEST LONDON HOSPITAL AND TO THE WEST END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM.

V.[1]

SYSTEMS OF TREATMENT; FADS AND FADDISTS.

EVERY physician tends after some years of experience to settle down into certain stereotyped methods of treatment of his own, and it is safe to say that these are never exactly the same for any two physicians. From this it is manifest that great latitude is allowed in treatment. This is due partly to the fact that the same malady may often be cured by many different means, but chiefly it is the result of the chaotic state of therapeutics. Of all the inexact sciences therapeutics is probably at the present day the most inexact and the furthest from reduction to a rigid system; and this is not because of any want of enthusiasm in those who devote themselves to it, but from the inherent difficulties it presents. As a consequence opportunity is offered for the introduction of a multitude of methods and of endless cranks and fads. We are like children wandering in the dark seeking for the light, and it is often impossible when a new treatment is advanced to say whether it will prove a mere will-o'-the-wisp or a true guide. Our ignorance does not permit us at once to silence the originator of what may ultimately prove a valueless—it may even be harmful—treatment; we are compelled in fairness to give him a hearing, and some of us, in the extremity of impotence, may even be persuaded to try the treatment ourselves, and it may be years before it is relegated to the oblivion it deserves. Nothing better shows the unsettled and nebulous state of present-day therapeutics than the fashion which prevails in treatment, pharmacological or other. It is scarcely an exaggeration to say that here fashion is as fickle and changeable as it is in dress. Every dispenser can testify to the truth of this so far as drugs are concerned.

One obvious moral is deducible from these considerations. It is highly undesirable, not to say blameworthy, for the physician to advocate a new treatment without first thoroughly testing its efficacy. After Newton had been working for some years at his theory of the law of gravitation there was still wanting some evidence which should conclusively prove his point; so instead of publishing his views to the world he locked up his papers in a drawer where they remained for 17 years. When he again worked at the subject the needful evidence was forthcoming and the law was established upon an enduring basis. One can scarcely look for such restraint among our modern therapeutic enthusiasts, but it ought not to be too much to demand of them that they should at least make moderately certain of the efficacy of their methods before giving them to a too credulous world. Neglect of this precaution is burdening medical literature with much that is valueless and rendering it an increasingly hopeless task to winnow the grain from the chaff. The worthlessness of such communications is suggested by the fact that it is precisely the least eminent who are most prodigal of new methods. By all means let us seek to advance therapeutics and be on our guard against a paralysing and deadly routine which is fatal to all progress, but let us also beware not to advocate a new treatment before we have well tested evidence of its efficiency.

Every physician who is worthy of the name has his fads, and it is perfectly right and proper that he should, provided that they have a sound basis; for faddism carries with it a firmness of conviction and an enthusiasm which issue in energetic action, and inspire the patient with a wholesome and most salutary confidence. What the physician has to be on his guard against is a narrow faddism. Let him have his fads, but let them be as broad-based as medicine itself. Note this significant fact, that fads become more and more narrow as the faddists stand lower and lower on the ladder of eminence. If a physician has one all-absorbing fad, and more especially if that fad rests upon a doubtful basis, depend upon it his mental horizon is limited; indeed, some faddists come perilously near the "fixed idea" in their fads, one notion dominating their entire medical thought.

It is nevertheless a fact that some even of these narrow faddists achieve considerable success in practice, and for this reason, that the method of the faddist may be, and often is, well suited to a particular class of case, and, being carried out with enthusiastic conviction and persistency, does do undoubted good in those cases; no small part of the good resulting from the faddist's belief in himself and his system, which begets a like faith in the patient, thus bringing into action the potent factor of suggestion. Moreover, the faddist *has* a system, and it is often better to have a system of some sort, even though it be a poor one, than none at all. Hence the faddist often achieves brilliant results where others have failed, and the patients he cures bruit his fame abroad, and so increase his practice, while those who have got no good from his treatment are more likely to hold their peace.

Now, if a narrow faddism can do so much the obvious moral is that we should carefully study the methods of all the faddists and seek to apply them severally to their appropriate cases. Therein lies the difficulty—to fit the treatment to the disease. It is easy enough to apply the same cut-and-dried treatment to each and every patient, but to apply the correct method to every case is a much more difficult matter; this it is that tests the true skill of the physician. The really great physician is a universal faddist. Speaking for myself, I confess that I am ready not only to listen to the views of the legitimately qualified faddists, but I have gone out of my way to study the methods of that large army of practitioners who have not been admitted within the portals of the profession, and I have learned much that is useful from them. Some of their methods well repay study.

Interesting and instructive though it might be I forbear to give an exhaustive list of the fads of our profession, and will refer to a few only. Some are for starving all their patients, others for feeding them up; some believe in alcohol, others in staunch teetotalism; some are for a strictly vegetable diet, others for a mixed diet; some hold that little fluid should be drunk, others that it is well to drink copiously; some have a profound faith in drugs, others place little reliance on them; then there are the grape cure, the water cure, the raw meat cure, the sunlight cure, the mud cure, and a host of other panaceas, each and all of which doubtless do good in certain cases: the mistake is to suppose that any one is universally applicable.

There are also unjustifiable and pernicious fads. We find one medical man resorting to a wholesale amputation of the clitoris, another referring all the ills of the body to the inferior turbinate bones and advocating the knife accordingly. It is pitiable indeed to think what mutilations have been inflicted from such mistaken notions; and yet it is probable that there is scarcely any system of treatment which might not do good to some particular case. Were we to remove the clitoris from a thousand women in succession we should as likely as not benefit some one among them. I care not how far-fetched or eccentric the treatment we adopt, it will

[1] Nos. I., II., III., and IV. were published in THE LANCET of Jan. 5th (p. 51), 12th (p. 122), and 19th (p. 201), and Feb. 2nd (p. 348), 1901, respectively.

in all probability do good in some cases. Let us feed all our patients on boiled acorns, or starve them for a fortnight, or order them to drink many gallons of water daily, and although doubtless we shall kill many we shall stand a good chance of curing a few.

ANNUAL REPORT OF THE MEDICAL OFFICER OF HEALTH OF THE ADMINISTRATIVE COUNTY OF LONDON.

THE report before us, which relates to the year 1899, is the eighth of a series the first number of which was published in 1892, just two years after Mr. Shirley Murphy's appointment as medical officer of health of the County of London. The report is divided into two parts. In THE LANCET of Jan. 5th we noticed Part II. which deals principally with questions of sanitary administration somewhat briefly in a leading article. To-day we commence a review of Part I. which treats almost exclusively of the vital statistics of the metropolis. From a medical point of view this is in many respects the most important section of the work, and to its preparation Mr. Shirley Murphy has evidently devoted learning and energy. Having perused it with care we are able to say that it compares favourably with any of its predecessors; in regard to many we have spoken in terms of high commendation. In our judgment the facts in this year's rep rt are skilfully arranged and classified: Mr. Shirley Murphy presents them in such a fashion that the reader should find no difficulty in apprehending the true bearing of the lessons they teach—lessons which he emphasises with good effect for the instruction of the public, and especially for the guidance of the London County Council who have hitherto shown a commendable disposition to act in accordance with his advice. A further object will unquestionably be attained by the publication of these useful reports, for they will shortly come to be recognised as the standard British authority to which constant reference may be made in regard to the prevalence as well as the intensity of the various epidemic and endemic diseases from time to time, and also in regard to the measures which experience has shown to be most appropriate for the suppression of sickness and for the preservation of the public health in a vast and thoroughly typical urban community.

The population of the administrative county of London estimated to the middle of 1899 was 4,568,689. The populations of a considerable number of the existing sanitary districts of London are very small; in 13 out of the 43 they are below 50,000, whilst in five cases they do not reach 25,000. It is well known that rates of birth or of death calculated on small numbers of the living are unreliable. Accordingly, inasmuch as the re-adjustment of metropolitan areas which has recently taken place reduces their number whilst increasing their size, the change must be regarded as an advantageous one from a statistical standpoint; for, according to the best estimates available, we find that one only of the new London boroughs will contain less than 50,000 inhabitants, whereas all but six of them will number more than 100,000. Particulars of the rates of birth and the general death-rates of the sanitary areas of London have already been noticed in these columns in connexion with the annual summaries of the Registrar-General; we shall, therefore, not refer to them further now. Mr. Shirley Murphy, however, carries his analysis of mortality much farther than it is carried in the Somerset House returns and thus suggests additional points for consideration. In Table I. of his report Mr. Shirley Murphy gives the means of comparing the mean annual deaths in the nine years 1891-99 with the number that would have occurred had the death-rates of the 1881-90 period been maintained throughout the nine following years, and the annual number of lives gained or lost in the later period at each age-group is shown. He further expresses this gain or loss in terms of "life capital," which is obtained by applying the mean future lifetime (as ascertained by a life-table) to the number of lives gained or lost at each group of ages. By this means he shows that during the last nine years there has been a mean annual saving in London of 4095 lives, representing a mean annual salvage for 172,763 years of "life capital." The foregoing is a more accurate method than that which is ordinarily adopted for showing the effect on a community of fluctuations in the death-rate, and it is one which we hope shortly to see universally adopted. This can be done with facility by any medical officer of health who will provide himself with a life table of his district and learn to use it. As regards the County of London Mr. Shirley Murphy shows that the number of lives gained annually has increased in each period from 1891-94 up to 1891-98, although in the following year there was a slight decline. On the other hand, the proportion of "life capital" gained to each life saved has decreased in each period up to 1891-98 and has increased in the period 1891-99. This apparent contradiction is due to the fact that the amount of "life capital" gained is not directly proportionate to the number of lives saved, but is dependent also upon the ages at which the saving is effected. Mr. Shirley Murphy next proceeds to show the causes of mortality in respect of which there has been a saving or a loss of "life capital." We have not space to follow him in detail, but we may note his generalisation, which is to the effect that "the net gain of life and 'life capital' secured in London is a balance between gains and losses from particular causes of mortality, and that while in respect of some of these causes, such as phthisis, there has been gain in each of the periods compared with 1881-90 among persons both under and over 25 years of age, in others, such as cancer, there has been loss in practically all of these periods at each age-group. Again, in respect to certain other causes of mortality this constancy is not manifest and often gain in one age-group is in the same period attended by loss in the other age-group."

Infant mortality is now universally accepted as the most reliable test of sanitary condition because of the certainty wherewith it can be computed, wherever an accurate register of births and deaths is available. The deaths occurring in any community, great or small, are calculated directly on the births, whilst the uncertain, and, when at long distances from the census, wholly unreliable factor of population is altogether eliminated. Infant mortality in the Administrative County of London during 1899 was in the proportion of 166 per 1000 births, a rate which is somewhat in excess of the average. London had in the period 1889-98 a lower infant mortality than had any other great English town of more than 200,000 inhabitants except Bristol and West Ham, and in 1899 a lower infant mortality than any such town except Bristol. In the several sanitary districts the rates varied considerably, but by grouping these areas it appears that the eastern districts had the highest infant mortality—namely, 179—and the northern the lowest, 154, the infant mortality of the southern, central, and western groups being intermediate between these extremes.

In connexion with the vital statistics of London we are pleased to notice that the Registrar-General now publishes in his weekly return a table giving the number of new cases of infectious disease notified in each of the London boroughs. As the Registrar-General's returns are widely circulated, both in this country and abroad, the publication of this additional information for London in the return for the first week of the century is an event upon which the authorities at Somerset House as well as at Spring Gardens are to be congratulated.

(To be continued.)

UNIVERSITY OF CAMBRIDGE.—The special board for biology and geology have recommended that the annual grant of £100 made by the University towards the maintenance of a table in Dr. Dohrn's Zoological Station at Naples should be continued for a further period of five years.—The Senate has authorised the obtaining of specifications and tenders for the erection of the Humphry Museum as a part of the new medical school buildings. It is to be hoped that additional contributions to this memorial of a great teacher will be received in order that its completion may be insured without delay. The old museum, which was structurally unsafe, has now been demolished.—Sir M. Foster has been appointed an additional member of the syndicate for the provision within the University of instruction in military subjects.—Dr. Rivers has been appointed a member of the Moral Sciences Board.—At the congregation on Jan. 31st the following degrees were conferred. M.B. and B.C.: E. E. Glynn, Clare; R. A. Walker, Clare; and J. P. Candler, Corpus. M.B. only: S. V. Pearson, Emmanuel. B.C. only: W. H. O. Woods, Selwyn Hostell.

Obituary.

BOWATER JOHN VERNON, F.R.C.S. ENG.,

OPHTHALMIC SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

MR. B. J. VERNON was the second son of the late Rev. Mark Henry Vernon, who was for 40 years vicar of Westfield in Sussex. He was born Oct. 23rd, 1837, and died on Jan. 28th, 1901. At the early age of ten he was entered at Marlborough College where he remained till Midsummer 1856. He there obtained a thoroughly sound education and it will surprise some of the friends of his later life to learn that he was a notable athlete, easily distancing all his competitors at the high jump, in hurdle races, and in short-distance running. In advanced life the deliberate manner in which he habitually moved concealed to a large extent his real strength of limb and capability of exertion. He may be said to have entered the profession by becoming a pupil at the Sussex County Hospital, Brighton, under the immediate supervision of Mr. Jowers, a highly intelligent surgeon, and he remained here, familiarising himself with general medicine and surgery for three years. He then came to London and entered St. Bartholomew's Hospital. After the usual three years' attendance upon lectures he was appointed in 1862 house surgeon for a year to Mr. Wormald and for a second year to Sir James, then Mr., Paget. He took the hospital scholarship in 1862. He passed the Membership of the Royal College of Surgeons of England and the Licentiateship of the Royal College of Physicians of London in 1862 and took the Fellowship of the College of Surgeons in 1864. In the meanwhile he had acquired so good a knowledge of anatomy and was so clean and excellent a dissector that he was made demonstrator of anatomy, which post he held for several years.

When the ophthalmic wards were opened at St. Bartholomew's Hospital in the summer of 1870 he was one of the two surgeons who were appointed—a piece of advancement for which he was indebted to his having been long in attendance at the Moorfields Ophthalmic Hospital and to his having been for some years curator of the museum. This latter post not only afforded him frequent opportunities of seeing the most advanced methods of treatment in ophthalmic practice in the hands of such masters as Sir William Bowman, Mr. Critchett, and Mr. Hulke, but also enabled him to pursue his natural bent for microscopical research, and indeed throughout life he was an excellent microscopist and could prepare, mount, and describe a rare specimen with artistic skill. His hands were adapted for such work. Before he suffered so much from rheumatism his long slender and firm but supple fingers used knife and forceps and scissors with unerring precision. He was an original member of the Ophthalmological Society, which was formed in 1870, though he only attended one or two of the earlier meetings and declined being elected upon the council on grounds of health. He was attached as ophthalmic surgeon to the Great Northern Hospital, and for no less than 27 years to the West London Hospital, in the affairs of which he took a very active interest, acting as secretary to the staff for several years. He was extremely regular in attendance at both places. He had all but completed his term of service at St. Bartholomew's Hospital at the time of his death, as he would have had to retire by seniority next year in accordance with the rules of the hospital.

His health never appeared to be strong; he suffered from indigestion and in the later period of his life from rheumatism or rheumatic gout, which was probably inherited, and affected chiefly the wrist-joints, which were occasionally very painful and swollen, though without appearing to interfere in any way with the neatness and delicacy of his operations. He has often said that at such times if he were left in a room with a closed door he would find himself quite incapable of getting out from the impossibility of turning the handle. A friendly grasp of the hand was appreciated in more senses than one and could not be reciprocated. He was essentially orderly and methodical in all his work. He practically organised the ophthalmic department of St. Bartholomew's Hospital as it now stands. He was an admirable clinical teacher. With a considerable fund of quiet humour he would elicit the chief facts of each case as it was presented to him. If the patient was admitted the notes of the house surgeon were carefully scanned and criticised and material points that had been omitted were added. He was never anxious to operate nor did he ever appear to be desirous of showing his address in the use of instruments. In every operation he gave to the onlookers the feeling that it had only been undertaken because absolutely necessary and that having been determined on it was done as dexterously as possible. He was never hurried, never taken by surprise. Every stroke told; every emergency was anticipated; and it was rare indeed for one of his cases to do badly. His opinion was highly esteemed, not only by his own colleagues, but also by many of those to whom he had given instruction, which secured for him a remunerative but very unostentatious practice. He kept himself well abreast of modern ophthalmological research and there were few proceedings that promised success he did not try at St. Bartholomew's Hospital, though the natural bent of his mind was eminently conservative.

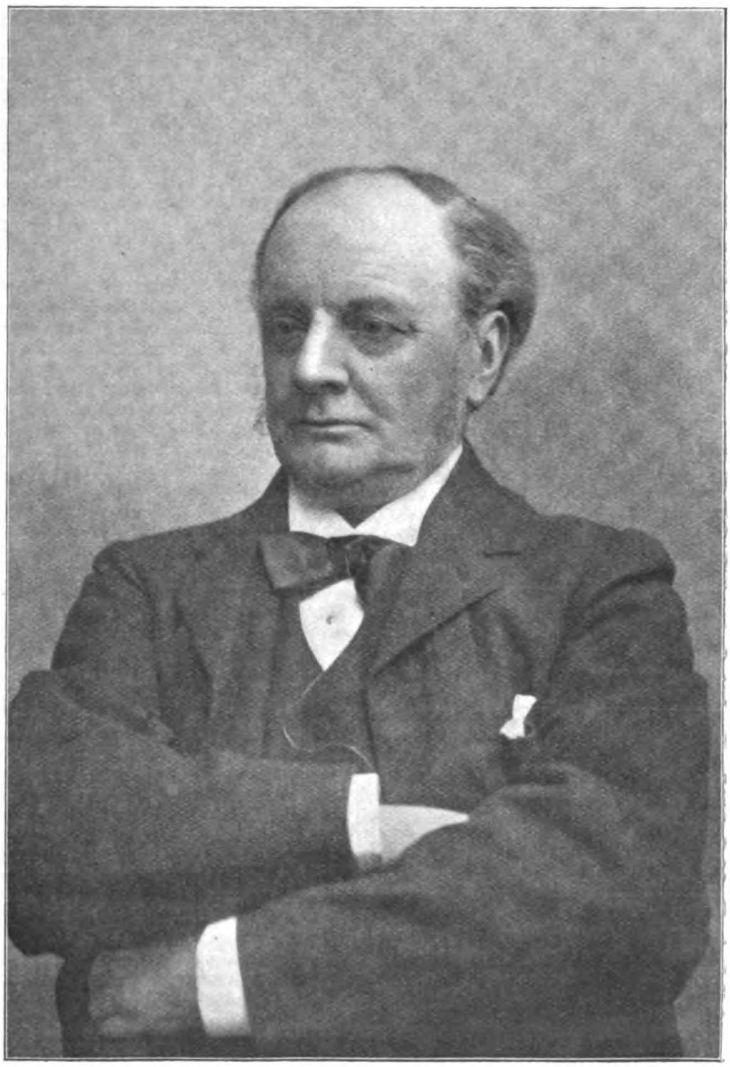
His interests were many and various. He was a keen sportsman, and probably the greatest pleasure he had was to run down to his old friend, John Henry Salter of Tolleshunt D'Arcy, for a day or two in September and bring down a few birds after a stiff walk over the stubble. On such occasions he would return to his work with a firmer and more elastic tread and perhaps with a ray of colour to brighten his naturally dark complexion. He was fond of plants, knew most of the English field flowers by name, and no more grateful remembrance could be sent him by a friend in the country than some wildling of nature orchid it might be, or cyclamen or parnassia, which he would wear as a buttonhole. He loved animals too, and his interests were divided between dogs and birds, the latter, perhaps, claiming most of his attention. He kept many canaries of pure breed, and at one time obtained several with pink feathers by feeding them largely on Chili pepper, but ceased the experiment when he found that some died with small abscesses in the liver, which he attributed to the effects of that fruit. He was of liberal disposition and not unfrequently helped with gifts of money necessitous out-patients who presented themselves at his desk when he saw that food rather than medicine was wanted. Also which was perhaps a still greater tax on his generosity, he would give to a young friend one of his favourite linnets or canaries.

The end came suddenly. He had been at the hospital on Jan. 19th and saw both his in- and out-patients, though complaining of cough and cold. On Sunday, Jan. 20th, he had some kind of spasm of his heart perhaps accompanied by dilatation and causing intense dyspnœa; a second or third attack proved fatal, and thus St. Bartholomew's Hospital was deprived of one of the most gentle, kindly, courteous souls it has ever nourished. The conservatism and loyalty of his character were curiously shown in the fulfilment of his own desire, expressed on more than one occasion, that having been born in the year of the Queen's accession he should be content to end his days with the close of the reign. The little group of mourners who surrounded the grave in which his remains were being deposited—his relatives, his able colleague, Mr. Jessop, and his attached former house surgeons, Dr. J. Attlee, Mr. E. W. Brewerton, and Dr. J. A. Nixon—could hear distinctly the booming of the guns which saluted the body of the Queen as it was borne across the Solent that winter afternoon. Whilst it deepened the impressiveness of the ceremony no circumstance, could he have known it, would have afforded him greater satisfaction.

Mr. Vernon was not a voluminous writer, his energy being chiefly expended in teaching. He contributed, however, several articles to the St. Bartholomew's Hospital Reports. One of these papers was on Congenital Myopia, another on Herpes Ophthalmicus, and a third on Tubercle of the Eye. All of these were characterised by lucidity of expression and gave evidence of care and research. He also for some years supplied reports on ophthalmology to the *Medical Record*.

JAMES EDWARD PRICHARD, M.B. OXON., M.R.C.S. ENG.

DR. JAMES EDWARD PRICHARD died at his residence "Combedale," Redland-road, Bristol, on Feb. 2nd in his fifty-second year. The deceased, who was a son of the late Dr. Augustin Prichard, of Clifton, and a brother of Mr. A. Prichard, senior surgeon to the Bristol Royal Infirmary, received his medical education at the University of Oxford and University College Hospital, London. He graduated



BOWATER JOHN VERNON, F.R.C.S. ENG.

LIBRARY
OF THE
UNIVERSITY OF ILLINOIS.

B.A. and M.B. at Oxford in 1879, and took the diplomas of M.R.C.S. Eng. and L.S.A. in 1878 and 1879 respectively. After holding the appointments of house physician at University College Hospital and house surgeon at the Tiverton and Swansea Hospitals, Dr. Prichard commenced practice in Bristol, and at the time of his death held the appointment of surgeon to H.M. Prison at Horfield. The deceased was vice-chairman of the Horfield School Board before the extension of the city boundaries. Dr. Prichard had suffered from carcinoma of the bowel for some time and a few months ago Dr. James Swain performed colotomy for his relief. Dr. Prichard, who was unmarried, was very popular with his fellow-citizens and will be much missed in Clifton and Bristol.

SEVENTH REPORT BY MR. VICTOR HORSLEY TO THE REGISTERED PRACTITIONERS OF ENGLAND AND WALES.

SINCE my last report of the proceedings of the General Medical Council some important events have occurred in the work of the Council: the English College of Physicians and Surgeons have repudiated their obligations under the Medical Act of 1886; the question of medical aid associations has been further advanced; the indefensible confusion of the finances of the Council has been further exposed and will, it may be hoped, shortly be remedied; certain serious penal cases involving in two cases new points have been decided; and finally the *personnel* of the Council has been altered with, as a result, a notable improvement in the conduct and progress of business.

THE REVOLT OF THE ENGLISH COLLEGES AGAINST THE MEDICAL ACT, 1886.

The most serious attempt that has ever been made to injure the Medical Act of 1886 is the recent revolt of the Royal College of Physicians of London and the Royal College of Surgeons of England against the authority of the General Medical Council. It will be remembered that the Act of 1886 was drawn up in the hope that a one-portal system might in substance be arrived at by honourable understandings whereby the guilds and corporations should sink their individual claims more completely than had been provided for in the Act of 1858. Since the foundation of the Council by the Act of 1858 its proceedings have often been disfigured by attempts on the part of one or more corporate bodies to gain special privileges or to retain what, though nominally termed ancient rights, are in effect provisions which are disadvantageous to their competitors in diploma granting. It has, however, been reserved for the College of Physicians of London and College of Surgeons of England to adopt an attitude in regard to the recent educational regulations of the Council which promises to resuscitate the worst features of the earlier troubles of the Council.

The matter at issue raised by the Colleges is simple, being only question of the right of the Council to decide where a student's science career can best be passed, but it is made by some to embrace the wider question whether the Council has any statutory authority over the earliest stages of medical education. Thus it is contended by the English Colleges that the Council has no authority whatever over students at any period of their education and that the edicts of the Council on the subject of the curriculum which have from time to time been, in accordance with the slipshod practice of the Council, termed recommendations, resolutions, suggestions, &c., are not in any way binding on the corporate bodies.

The present dispute turns on the interpretation of Section 18, &c., of the Medical Act, 1858. The terms of the section leave no doubt in the mind of an impartial reader that the Council was intended by the Act to have complete authority over all stages of the medical curriculum and of course it has always worked on that understanding. But as that position is now contested by two of the corporate bodies it is obvious there are only two courses open to the Council. Either a so-called friendly action can be tried at great cost to the profession, with probably only the result of obtaining a worthless decision—for, as the recent case of Hunter shows, our highest judicial authorities know nothing about medical education or even about the granting of medical degrees by the universities. Or the matter can be settled in an amended Medical Act in which the powers and duties of the Council would be laid down in such minute detail as to prevent the possibility of any corporation seeking to separate itself from the federation which the Council constitutes. The previous unfortunate experiences of the Council in its actions against the College of Physicians and the late Mr. Hunter will, it is to be hoped, prevent any resort to litigation in this really contemptible affair. It may be hoped that the time and attention of the Council and profession have not been wholly wasted in this matter, as such demonstrations of self-interest on the part of a corporation can only have the effect of furthering the adoption of the much required one-portal system. The general feeling of the Council, it may be added, is far more favourably disposed towards the one-portal system than it was three years ago.

MEDICAL AID ASSOCIATIONS.

The attitude of the Council on this subject has become considerably strengthened, but, as will be seen from the press reports of the last session of the Council, the report of the Medical Aid Association Committee as presented was misleading and still remains unsatisfactory. The matter at issue is the question of the formation of a conciliation board. It will be remembered that this important subject was first raised in 1899 by Dr. Bruce, Direct Representative for Scotland, and it would naturally be a great gain if his original proposal could be successfully accomplished. The idea of a conciliation board, as proposed by Dr. Bruce, was that representatives of the profession and representatives of the friendly societies should meet in conference and draw up heads of agreements on the fundamental principles underlying the proceedings and the working of the medical department of the friendly societies. But in 1898 the General Medical Council appointed certain members to receive a conference of the leading members of the friendly societies so that there might be an interchange of views before the constitution of the conciliation board could be arranged, and at this meeting the all-important question of agreeing upon a wage limit for membership was brought up. The representatives of the friendly societies informed the representatives of the General Medical Council that under no circumstances would the friendly societies consent to this question being raised at a conciliation board. At the annual conference of the officers of the friendly societies that same year this hostile attitude was affirmed. At the time when Dr. Bruce's project was mooted in the General Medical Council I drew attention to this matter and to the primary importance of determining before the meeting of a conciliation board that any such board must have full power to discuss all questions which affected the interests of the profession and above all the fundamental question of the financial position of persons who might seek to obtain the special medical benefits offered by a friendly society. If the conciliation board commenced work with their hands tied to the extent proposed by the representatives of the friendly societies it is plain that any medical representatives who took part in such proceedings would be sacrificing the interests of their fellow-practitioners. The report of the Medical Aid Committee presented last session is unsatisfactory because it in nowise provides for the safeguarding of this point and because it conveys an erroneous rendering of the attitude of the British Medical Association on this question. It is, however, only an interim report. The final report is promised for the next session.

THE FINANCES OF THE COUNCIL.

I drew attention two years ago to the condition of the finances of the Council and pointed out that for a number of years the income had been steadily falling whereas the expenses had been year by year rapidly increasing; further, that for years there had been a deficit, this indeed amounting in 1898 to over £2000 on a turnover of £10,000; that although to meet this deficit and increased expense there were certain funds in the possession of the branches of the Council the financial arrangements between the Council and its branches were not only very confused but in part positively illegal, and that the Irish Branch was practically bankrupt. These statements, though officially denied by the treasurers, Mr. Bryant and Sir Dyce Duckworth, have been fully confirmed by the events and disclosures of the last two years. On Dec. 4th, 1899, I obtained the appointment of a special finance committee to examine into

the facts. That committee consisted of the trustees of the Council and its branches as well as the ordinary finance committee. The report which they furnished the Council was so useless that I moved that the committee resume their work, and I specified three references that the committee were to report upon—namely: (1) the financial position of the Council and its branches as regards assets and liabilities; (2) the relations of the income and expenditure of the Council and its branches for the last 10 years; and (3) the measures that appear to be desirable to place the Council's finances on a satisfactory basis. In presenting their report at the recent session the committee deliberately refrained from reporting on the most important of these references—viz., how the finances of the Council could be put upon a proper basis—and instead of reporting properly on the other two the committee merely made a few suggestions for small domestic economies connected with the arrangements of the Council meeting. Further, the general narrative of the report presented at the recent session by this committee was written in a highly optimistic tone, and though an annual deficit of £110 was admitted on the average of the last 10 years the committee stated that the condition of the finances of the Council was not serious. It is hardly credible, but nevertheless the fact, that the Finance Committee, the members of which formed the majority of the special committee, stated in even their imperfect report six months before that the average yearly deficit on the last seven years was over £600, that to cover this the Council was "spending its capital," and that "the Council ought seriously to consider whether it is not possible to reduce its expenditure to a very large extent." It is quite obvious that these two reports are self-contradictory. The feeling in the Council of dissatisfaction with the way in which the finances were being dealt with was so marked that in spite of a speech by Dr. MacAlister, well calculated to mystify anyone not familiar with the facts, and a personal appeal by the President to pass the report and so close the matter, the debate was adjourned in order that the subject should be thoroughly threshed out at the next session. Possibly the chairman of the Business Committee, Dr. MacAlister, may again succeed, as he has done in the last three sessions, in shelving this important if unpleasant subject from day to day until the last day of the session when everything is hastily rushed through, but I have every hope that the last two years' work on this point will finally result in a thorough reform of the administration of the funds of the Council.

PERSONATION OF REGISTERED PRACTITIONERS BY FRAUDULENT PERSONS.

At the November Session, 1898, I carried a motion in the Council instructing the Executive Committee to report on the subject of fraudulent personation of practitioners and on the best method of securing accuracy of registration. The report of the Executive Committee being useless the Council on my motion appointed a special committee to deal with the subject. The committee, of which I was appointed chairman, reported fully two years ago, but by reason of strong official resistance and continual shelving of the report by the chairman of the Business Committee, Dr. MacAlister, the question and the report have not yet receive adequate consideration.

PERSONNEL OF THE COUNCIL.

The profession is to be sincerely congratulated upon the fact that by reason of various changes in the *personnel* of the Council questions involving progress and reform are certain to receive much more favourable consideration in the future than in past sessions of the Council.

Jan. 31st, 1901. VICTOR HORSLEY.

PRESENTATIONS TO MEDICAL MEN.—At a numerously attended meeting of friends and inhabitants of Llanerchymedd, Anglesey, held on Jan. 30th, Mr. William Evans, L.R.C.P. Edin., M.R.C.S.Eng., on his retiring from medical officership of the Llanerchymedd district, covering the long period of 48 years, and medical officer of the workhouse since its opening in 1869, was presented with an address, a portrait to be preserved in the guardians' board-room, a silver tray, and purse of gold, as tokens of esteem and regard and a recognition of the fidelity with which he discharged his official duties.

THE RECENT OUTBREAK OF DIPHTHERIA AT OLD HEATH, COLCHESTER.

THE *Essex Telegraph* of Jan. 5th, 1901, reported that the sanitary misfortunes of Old Heath, a hamlet on the outskirts of Colchester, to which one or two references, direct and indirect, have already been made in our columns, culminated in an outbreak of scarlet fever and diphtheria. These two diseases, so fatal during the early years of life, have now fortunately subsided, but not without some loss of life.

There are many small communities, especially such as are situated in the outlying districts of large towns, where outbreaks of scarlet fever and diphtheria are present, and there are some where they frequently recur; and, as a rule, the only lesson, if any, to be drawn from such epidemics is that the locality requires some obvious sanitary reform—a drainage scheme, drastic treatment of irresponsible landlords, an isolation hospital, or a more modern method of administration. But the plight of Old Heath, Colchester, was associated with, or rather perhaps resulted in, a correspondence which is of general interest, and it may be instructive to our readers to have the whole story before them, seeing that it involves a consideration of the question as to how far the method of treatment adopted by a public official can reasonably be challenged.

The Public Health of Colchester at the End of the Third Quarter of 1900.

At the beginning of October, 1900, Dr. George Brown, the medical officer of health of Colchester, published a report which showed that the public health of the borough was not wholly good, and his figures mentioned seven cases of diphtheria at that time. The seven cases of diphtheria had, he stated, occurred in different quarters—two in the Canterbury-road, one at Hythe, and four at Old Heath—though he gave it as an opinion that "the malady has evidently a local origin, local in being caused by the houses themselves and their surroundings rather than the causes being attributable to the whole district." About this time the attendances at the Old Heath Board School were very much lowered by the abstention of a large number of children through sickness, and the school was closed at Dr. Brown's instance on Oct. 1st, not to reopen for continuous instruction until Jan. 21st, 1901. This sickness seems to have been greatly prevalent in the Old Heath district and Dr. Brown thus refers to it: "In addition to the diphtheria which has affected the district a large number of children have suffered from quinsy or inflammation of the throat. ..... The disease was of a septic or poisonous type caused by the air being impregnated by a large quantity of manure spread over a field on the west of the village." Dr. Brown's report does not show whether his diagnosis of quinsy was made from actual inspection of the throats of the sufferers. The report closed with the announcement that the infectious hospital of Colchester, at Myland, contained certain cases of diphtheria—four apparently, but the wording of the paragraph is not very clear.

The Value of Antitoxin.

There was nothing on the face of Dr. Brown's report of a particularly sensational character, but it proved to be the starting point of a local difference of opinion the cause and developments of which are of considerable importance not only to all medical men and sanitary authorities but to the public. On Oct. 20th there was published in the *Essex County Standard* a correspondence between Mr. E. A. Hunt, senior surgeon to the Essex and Colchester Hospital and a member of the School Board, and the municipal authorities of Colchester. This correspondence we have already referred to in THE LANCET and the gist of it is as follows. On Oct. 4th Mr. Hunt found two children at Old Heath suffering from diphtheria. On the following day he found that a third child of the same family showed symptoms of diphtheria. He injected the children with anti-diphtheritic serum and notified the three cases as diphtheria to the medical officer of health who took the two elder children into the infectious hospital, but the third one, an infant, aged eight months, was not admitted Mr. Hunt

wrote for an explanation of this, and in his letter also asked whether it was the medical officer of health's "custom to use the antitoxin in diphtheria cases at the infectious hospital." The medical officer of health called upon Mr. Hunt and said that he had never found it necessary to use the antitoxin, and that the baby was not admitted to the infectious hospital because there was no room for it; and in a letter following the interview he promised "if I find it necessary to inject your patients or any other at the infectious hospital you may rest assured that it shall be done."

During October and November the health of Old Heath did not improve, several cases of diphtheria were notified and the school remained closed, as already mentioned. Mr. Hunt now took upon himself the task of attempting to explain through the lay press the merits of the antitoxin treatment of diphtheria, and this he did in a letter dated Oct. 19th, 1900, and published in the *Essex Telegraph* and *Essex County Standard* of Oct. 27th, pointing out that his objects in taking up the matter were "first, to advocate and advertise throughout the borough one of the most blessed remedies ever vouchsafed to man ..... and second, to remove the reproach from Colchester that in its infectious hospital this remedy was not in use." Later Mr. Hunt published a further argument in favour of the antitoxin treatment of diphtheria, reinforcing himself with the opinions of Dr. J. C. Thresh, the medical officer of health of Essex county, and of Dr. J. J. Macgregor, surgeon to the Essex and Colchester Hospital. Mr. Hunt stated that before the board school was closed 40 children were absent suffering from sore throat. These, he said, were the children described in Dr. Brown's report as suffering from quinsy or inflammation of the throat, but according to Mr. Hunt there could be no doubt that some, if not many, of these cases were diphtheria, for evidence had been submitted to him that in certain cases diphtheritic paralysis had ensued. On Saturday, Nov. 3rd, appeared a letter from the medical officer of health in the two newspapers above mentioned. Dr. Brown did not categorically state that he would not use the antitoxin in the treatment of diphtheria, but he said that "the Local Government Board has not yet advised any sanitary authority to use the much-vaunted antitoxin," adding, "I freely confess that I have not bowed the knee to the medicinal Baal in the treatment of this disease (diphtheria), but I do not in any way consider that this is the only or chief remedy in this malady, as the remedies employed at the infectious hospital for some years past have rendered antitoxin unnecessary, and I consider the results achieved there are incomparably superior and more satisfactory than those given by the serum treatment."

The School Board demand an Expert Inquiry.

Towards the end of October the Colchester School Board, feeling that some excellent work that had been done at the board school at Old Heath was being entirely sacrificed by the continued closure of the school owing to diphtheria, demanded an expert inquiry into the subject. Mr. Hunt moved a resolution at the meeting of the school board held on Oct. 26th to the effect that the town council should call the Local Government Board into consultation and that an expert in outbreaks of diphtheria should be sent to assist the council in endeavouring to discover the cause of the diphtheria and to stop its spread. This resolution was carried *nem. con.*

The *Essex Telegraph* on Nov. 10th contained a brief letter from the medical officer of health relative to the outbreak at Old Heath in which the following somewhat remarkable passage occurs: "But Mr. Hunt rushes into a long statement about a treatment of disease that under some circumstances he holds infallible as a means of cure and ignores another that experience and proof have proved itself of greater value in my eyes, yet he has never been charged as a fault for not using the safer remedy." On Dec. 8th the *Essex Telegraph* published the report of the medical officer of health for the month of November in which it was stated that "of 32 persons admitted to the infectious diseases hospital only one died, a child suffering from diphtheria, aged three, whom it was impossible to treat."

A Report of the Medical Officer of Health to the Sanitary Committee.

On Dec. 12th THE LANCET received from the medical officer of health a copy of a report made by him to the chairman and other members of the sanitary committee of the borough of Colchester on the occurrence of diphtheria at Old Heath and on the sanitary condition of that locality. In this it was stated that since 1894 a sewerage system has been carried out and that, in Dr. Brown's opinion, "the general health of the locality has of recent years greatly improved." The report also affirmed all the cases of diphtheria to be "of a mild type" and suggested as the origin of the outbreak "the effects upon the throats of the children attending Old Heath Board School caused by an offensive effluvium from some manure which was laid on a field near by previous to being ploughed in. At this time the air was muggy and humid and warm and a slight breeze from the west brought a very disagreeable odour with it to the schoolhouse and houses adjoining, and 22 of the children had an affection of the throat of a septic, but not of a diphtheritic, character, but of such a nature as to render the incursion of diphtheria easy and, in my opinion, render the children very liable to take on the malady." The report went on to state that orders were given for the ploughing in of the manure and the closing of the school. The medical officer of health expressly exonerated from blame both the water- and milk-supply of the locality, and recorded as his view that "the seriousness of the outbreak has been greatly magnified." But he held the housing of Old Heath as chiefly to blame. "I therefore regard," said the report, "the affection of the throat from which the children suffered was the *causa causans*, and the efficient agent was the kind of houses in which the children lived. The disease as a whole occurred in houses widely separate from each other, and it was most severe where the children were numerous and congregated in a small room or kitchen in the evenings, breathing the polluted air of their small abodes. In the houses where the tenants were few, if the disease occurred, it was comparatively mild and was soon recovered from."

The Question of Responsibility.

There is nothing novel in the fact of diphtheria recurring in a suburban locality and leading to the closing of a school, the sickness of many, and the death of some. But the particularly interesting and somewhat unique point in the story is the attitude of the medical officer of health towards the antitoxin treatment of diphtheria, an attitude which can both be criticised sharply and defended effectively.

It is quite without the province of THE LANCET to attempt to dictate to any qualified medical man that he should or should not use a certain remedy for a certain disease. No corporation has ever attempted to bind its members to a definite scheme of therapeutics, and for any sanitary authority to attempt to do this would not only be flat tyranny but would certainly, in our view, fatally narrow the scope of medicine. Therefore we cannot say in so many words that Dr. Brown ought to treat diphtheria patients with antitoxin, nor can we say that his sanitary authority should influence him to do so. But Dr. Brown is a public officer and not a private individual and can be reasoned with though not coerced. He is under the jurisdiction of the sanitary committee who have to think of what is due to the public and nothing else. They have not to weigh their feelings as to drugs, as to medical treatment, or as to private differences between individuals. It is their duty simply to see that the isolation of infectious cases is properly carried out, that an infectious hospital duly administered awaits the reception of such cases, and that nothing is done to render such institutions inoperative. Now the medical officer of health is not at liberty to the same extent that a private individual is to carry out an individual line of treatment. He is the servant of the authority who are themselves the servants of the community, and if the community desire the antitoxin treatment of diphtheria he would be well advised to let them have it. The Local Government Board have laid down no rules on the subject; he therefore cannot be compelled to use the modern treatment which is accepted by practically the whole medical world as valuable, but the awkwardness of his not doing so may be pointed out to him. Dr. Brown appears to possess some treatment of his own—at least he refers in his reports to some method of therapeutics which he has always found so useful as to render the antitoxin treatment unnecessary. If Dr. Brown has really discovered a treatment of his own, which is productive of better results than are admittedly obtained by the application of antitoxin used early, it is, it seems to us, incumbent upon him to

announce it to the world; but if he is referring to some local application to the throat it might perhaps serve to allay public anxiety if he were to explain the reasons why the local application precludes the use of such a commonly accepted remedy as antitoxin. We feel sure Dr. Brown would be considering the best interests of his district were he thus far to adapt himself to the circumstances.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN ordinary meeting of the Comitia was held on Jan. 31st, Sir WILLIAM SELBY CHURCH, the President, being in the chair.

The PRESIDENT referred in appropriate terms to the death of the Queen and proposed from the chair the following motion which was adopted in the usual manner:—

That this College humbly approach His Majesty the King and express its profound sorrow at the loss which His Majesty and the Royal Family have sustained, and at the same time assure him of our loyalty and devotion to his throne and person.

The SENIOR CENSOR (Dr. W. Cayley) in an eloquent speech proposed a vote of congratulation to the President on the honour conferred upon him by the late Queen, and referred to the work which the President had performed whilst serving on the Royal Commission appointed to consider and report upon the care and treatment of the sick and wounded during the South African campaign. Dr. Cayley especially commented upon the manner in which the Royal Army Medical Corps had been cleared from the charges brought against its members and further congratulated the President on his return.—The motion was seconded by the TREASURER (Sir Dyce Duckworth) and carried unanimously.—The PRESIDENT returned thanks to the College in well-chosen and modest terms, intimating that the honour spoken of by the Senior Censor reflected more to the College than to himself personally.

The SECOND CENSOR (Dr. C. Theodore Williams) proposed a vote of thanks to Dr. F. W. Pavy for having acted as pro-President during the absence of the President in South Africa.—This was seconded by the FOURTH CENSOR (Dr. T. H. Green) and carried unanimously.—Dr. PAVY returned thanks to the College for the resolution just passed.

The PRESIDENT announced that he had appointed Dr. Norman Moore Harveian Orator for the year and Dr. Judson Bury Bradshaw Lecturer, and that the Council had appointed Dr. W. H. Corfield Milroy Lecturer for 1902.

The following gentlemen having passed the required examination were admitted Members of the College: Francis Arthur Bainbridge, B.A. Cantab., L.R.C.P. Lond.; William Samuel Octavius Byrne, B.A., M.D. Dub.; Norman Bruce Elliott, M.D. Durh., L.R.C.P. Lond.; John Shields Fairbairn, M.A., M.B. Oxon., L.R.C.P. Lond.; Hugh A. McCallum, M.D. Western Univ., Ontario; Frederick Stephen Palmer, M.D. Durh., L.R.C.P. Lond.; George Eric Campbell Pritchard, M.A., M.D. Oxon.; Henry John Forbes Simson, M.B. Edin.; and Francis Hugo Thiele, M.D. Lond.

Licences to practise were granted to 130 gentlemen and diplomas in public health (conjointly with the Royal College of Surgeons of England) to eight gentlemen who had passed the necessary examination.

Communications addressed to the College were received (1) from the University of Birmingham, asking to be placed on the same footing as other universities as regards the acceptance by the College of certain of the university examinations in lieu of its own; (2) from the Incorporated Society of Medical Officers of Health, asking the support of the College to a representation they have made to the Local Government Board with a view to improve the statistical value of the returns of births, deaths, and notifiable diseases; (3) from the same, on the certification and classification of diarrhœa deaths; (4) from the General Medical Council, forwarding a resolution of Dec. 4th last announcing their adherence to their former resolution (June 7th, 1899) with reference to the registration of medical students; (5) from the same, forwarding the new rules, adopted by the Council on Dec. 5th last, for diplomas in public health granted after Jan. 1st, 1902; (6) from the same asking for a detailed list of exemptions granted by the College from any part of its examinations held during 1897, 1898, and 1899; and (7) from the secretary of the College of Surgeons (3) reporting certain proceedings of their council on Nov. 8th and Dec. 13th, 1900, and Jan. 10th, 1901; and (8) from the University of Glasgow inviting the College to send delegates to take part in the 450th anniversary of the founding of the University.—It was resolved on the proposal of the TREASURER, seconded by Dr. ALLCHIN, to accept the invitation.

Nos. 1, 4, 5, and 6 were referred to the Committee of Management.

A report, dated Dec. 8th last, was received from the representative of the College (Sir Dyce Duckworth) in the General Medical Council.

The following Fellows were elected Councillors: Sir George H. Philipson, Dr. J. F. Goodhart, Dr. F. de Havilland Hall, Dr. W. Ewart, and Dr. W. H. Dickinson (the last named in place of Dr. J. C. Thorowgood who has resigned).

The President nominated Mr. Bryan Farrer, jun., Standing Council to the College; Mr. J. Millar Thomson, F.R.S., was elected an examiner in chemistry in place of Dr. Laurie, who has resigned; and Dr. Andrew M. Paterson an examiner in place of Dr. A. W. Hughes, deceased.

The annual report, dated Jan. 15th, of the Conjoint Finance Committee and the quarterly report of the College Finance Committee were received and adopted.

A report was received and adopted from the Committee of Management dated Dec. 10th last. Amongst the various matters therein dealt with was the recognition of Cooke's School of Anatomy as a place of instruction in anatomy and physiology for candidates referred at the second examination.

A report from the Laboratories Committee dated Dec. 7th was received and adopted.

The REGISTRAR moved that By-law cxxxvi. be amended and re-enacted for the first time as follows, to render it conformable to the regulations of the Conjoint Board, the alteration consisting in the addition of the words printed in italics:—

A candidate shall not be admitted to the third or final examination till the expiration of five winter and five summer sessions from the date of registration as a medical student, *and of four winter and four summer sessions after passing Parts I. and III. of the first examination*, and of two winter and two summer sessions after passing the second examination.

Books and other publications presented to the library during the past quarter were received and the thanks of the College accorded to the donors.

After some further formal business the PRESIDENT dissolved the Comitia.

LITERARY INTELLIGENCE.—The Transactions of the Otological Society of the United Kingdom, a review of which appeared in THE LANCET of Feb. 2nd, page 334, are published by Messrs. J. and A. Churchill.

FOREIGN UNIVERSITY INTELLIGENCE.—*Erlangen:* Professor Richard Frommel will retire from the chair of Midwifery and Gynæcology at the conclusion of the current winter session.—*Halle:* Dr. Bumm of Basle has been appointed to succeed Professor Fehling.—*Heidelberg:* Dr. Witzel of Jena has been appointed Director of the Dental Institute in succession to Dr. Jung.—*Marburg:* Dr. Friedrich Schenck of Würzburg has been appointed to the chair of Physiology vacated by Dr. Kossel, who goes to Heidelberg.—*St. Petersburg (Military Medical Academy):* Dr. Walter has been recognised as *privat-docent* of Physiology.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The next general meeting of this association will be held at the London County Asylum, Claybury, on Feb. 14th, 1901, under the presidency of Dr. Fletcher Beach. The medical superintendent, Dr. C. T. Ewart and Dr. Eric France, and the steward will take members over the General Asylum, Claybury Hall for private patients, the Farm, and the Dibdin bacteria beds for sewage, on their arrival at eleven o'clock.—In the unavoidable absence of Dr. Mott a demonstration upon the Chemistry of Nerve Degeneration will be given by Professor Halliburton at three o'clock in the Pathological Laboratory of the London Asylums at Claybury.—A demonstration upon the Morbid Changes in Dementia by Dr. Joseph Shaw Bolton will also take place.—A paper will be read by Dr. Joseph Wiglesworth on a Case of Murder, the result of pure Homicidal Impulse

THE WAR IN SOUTH AFRICA.

WE said last week that there was but little to chronicle in the way of war news from South Africa and that things had reached a somewhat stagnant stage. But there are now signs of renewed activity. Horses and reinforcements in large numbers are being sent from this country and the colonies to the Cape. De Wet's force is moving towards Cape Colony, while General Knox's troops are endeavouring to head off the guerilla leader before he reaches the banks of the Orange river. Some seven columns of British troops are moving, or about to move, on a systematic plan over the whole country, and presumably on converging lines and in communication with one another. Whether any of them come up with the Boers or not remains to be seen. They will attempt to sweep the country of all supplies of cattle, forage, horses, and food crops, and try to drive the foe into circumscribed positions where, deprived of supplies, they will have to fight in order to live. That seems to be shortly the proposed method of future procedure. Among the killed during the capture of the post at Modderfontein, which was apparently rushed by a large body of Boers on a very dark night and in heavy rain, we regret to notice the name of Civil Surgeon Walker. The sick casualties continue to be rather heavy. The lists of those suffering or dangerously ill from enteric fever are long—to say nothing of the fatal cases. According to the latest return issued by the War Office the total reduction of the military forces through war in South Africa reported since its beginning and up to and including the month of January is:—

	Officers.	Non-commissioned officers and men.	
Deaths in South Africa	635	.....	12,354
Missing and prisoners	15	.....	922
Invalids sent home who have died ...	4	.....	265
Invalids sent home who have left the service as unfit	—	.....	1,734
	654	.....	15,275
			15,929

THE IMPERIAL YEOMANRY HOSPITAL, PRETORIA.

(FROM A CORRESPONDENT.)

IN addition to the field hospital, the bearer company, and the branch hospital at Mackenzie's Farm, the Yeomanry Hospitals Committee have sent out to South Africa two absolutely independent general hospitals, one at Deelfontein and the other at Pretoria. The latter hospital landed in Cape Town on July 16th, 1900, and opened at Pretoria for the reception of patients on August 18th.

The staff now consists of the following:—Commandant and principal medical officer, Surgeon-Major C. R. Kilkelly, Grenadier Guards; consulting physician, Dr. J. W. Washbourn; surgeons, Mr. A. R. J. Douglas and Mr. H. Williamson; physicians, Dr. Crowther Smith, Dr. Davies, Dr. Frost, and Dr. Hayes; quartermaster, Lieutenant Bruce, R.A.M.C.; and secretary, Mr. Vincent. Dr. F. M. Sandwith of Cairo and Dr. Langdon Brown who came out on short leave from their posts at home have returned and Dr. Brickwell has been invalided to England. The nursing staff consists of Miss Nisbet the matron, Miss Leggatt the assistant matron, and 35 nursing sisters. The *personnel* consists of one warrant officer, 25 non-commissioned officers, and 150 men.

The hospital is situated about two miles east of, and 300 feet above, Pretoria on the Megaliesberg range which bounds to the north the valley in which the town lies. It consists of a large two-storeyed house belonging to Mr. Beckett and of a number of tents, the total accommodation being 506 fully-equipped beds, 69 of which are for officers (Fig. 1). We give a sketch by one of the patients, Mr. G. A. Chadwick, 3rd Regiment Australian Bushmen. In the house there are seven rooms for sick officers containing 29 beds, and two rooms for men containing 18 beds. The latter are kept for medical and surgical cases requiring special treatment. One of the rooms in the upper storey is fitted up as an operating-room and an adjacent room is used for surgical instruments. The hall is used as a reading-room and the conservatory as a mess-room for the sick officers and medical staff. The rest of the house is used for kitchens, store-rooms, bath-rooms, and officers' quarters. Several verandahs around the house are a great boon to the patients who are able to sit up. A large outlying building at the back of the house is fitted up for linen stores, hardware stores, dairy, and an x ray room. Behind this building is an electric light installation fitted with an engine and a dynamo, by which the hospital (including the tents and grounds) is lighted.

The tents are pitched in the grounds, and just in front of the house there is a series of terraces with fruit-gardens and vineyards. The men's tents are divided into the following sections: medical section, enteric fever section, surgical section, and general section, the last-named being reserved for the less severe cases. In the medical section there are 30 tents, in the surgical section 12, in the enteric fever section 18, and in the general section nine, each tent containing six beds. The officers' tents consist of three tents for enteric fever cases and three for dysentery cases, each tent containing four beds. There is also a convalescent section for officers (consisting of four tents, each containing four beds) which is reserved for those officers who have sufficiently recovered to join in the officers' mess and who do not require the attentions of a nurse. The accompanying plan shows the general arrangement of the camp (Fig. 2). The mortuary, latrines, refuse pits, and receptacles for soiled linen lie to the west of the plan in a group. With the exception of the enteric fever section the tents are of the "E. P." pattern, which appears to be the best kind of tent yet made. They are economical in space, do not let in rain, and they withstand the worst storms. Their only defect is their weight which renders them difficult of transport. These tents are arranged in sets of three, thus forming "wards" of 18 beds, the "porches" in front of the doorways forming a covered way from one tent to another without interfering with the air-space between the adjacent tents. In some of the sections one tent in each "ward" is used as a day-room, four of the beds being removed to the other tents.

FIG. 1.

Sketch by Mr. G. A. Chadwick of the Imperial Yeomanry Hospital at Pretoria.

The enteric fever section is situated below the other sections, from which it is divided by a broad avenue. It consists of separate hospital marquees.

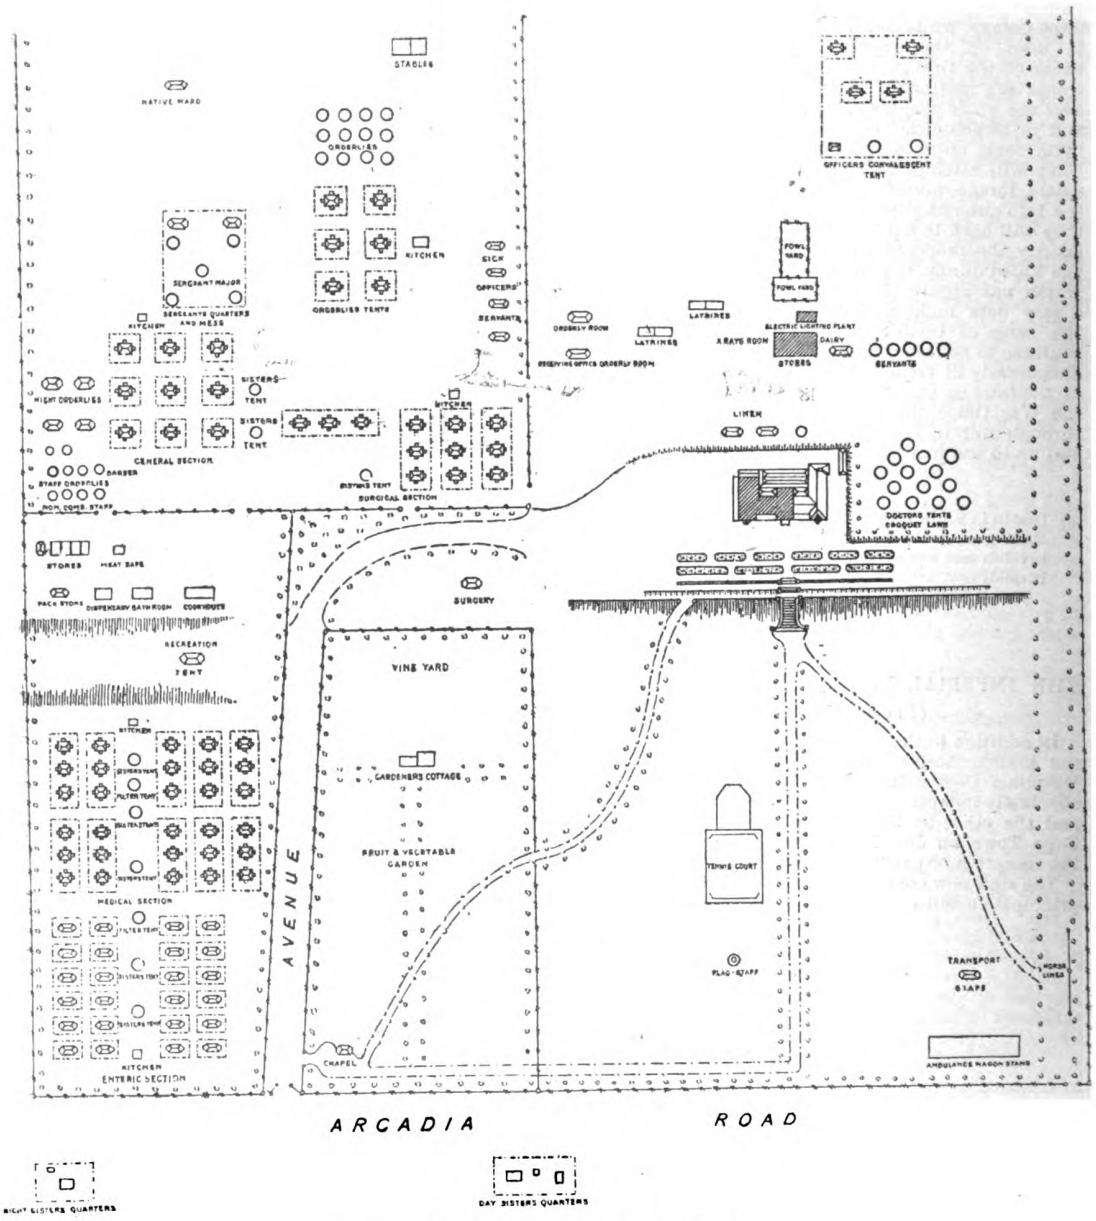
The medical officers (Fig. 3) live in double fly bell tents pitched above the croquet lawn by the side of the house. Two houses just outside the hospital grounds, formerly occupied by Mr. Reitz, the state secretary, and by Mr. MacFadyean, accommodate the nursing staff. One of these houses is used by the day sisters and the other by the night sisters. Both have been fitted with bath-rooms, and in the day sisters' house there is a mess-room and a kitchen. The *personnel* is accommodated in "E. P." tents and marquees pitched to the north of the main camp, with separate kitchen and mess. The sergeants, who also have their own kitchen and mess, live in bell tents. The natives employed about the camp, of whom there are about 100, are located some distance from the rest of the camp in cleverly built shelters made by themselves. A marquee has been fitted up for them as a hospital under the care of Dr. Davies.

Between the medical section and the tents for the *personnel* is a set of buildings consisting of a cookhouse, a bakehouse and lavatory, a dispensary, a provision store, a dry canteen, a pack store, and an ordnance equipment store. The chapel consists of a large tent and hours are fixed for services for all denominations. The whole of the camp looks very pretty and smart with the paths marked out by white stones and with little gardens in front of the tents.

The water-supply is derived from the Pretoria Waterworks. The water, which has been frequently analysed by Dr. Turner and Colonel Lane Notter, R.A.M.C., and found to be of excellent quality, is pumped up from the town into closed tanks. All the water used for drinking purposes is filtered through Berkefeld filters placed at intervals through the camp.

The sewage is disposed of by the pail system, but special arrangements are made for the disposal of the stools from cases of enteric fever or dysentery. The bedpans are taken to a special building and the stools are emptied into pails

FIG. 2.



Plan of the Imperial Yeomanry Hospital at Pretoria.

containing a disinfectant. Thence they are transferred to a large copper in which they are boiled and sterilised according to the method described by Major Cummings, R.A.M.C. The bedpans are left in the building to be washed and cleansed in a disinfectant and are ultimately returned to the wards. This method of treating infective stools is easy of application and most effective. There is very little offensive odour and with slight modifications it might be used with advantage in the fever hospitals at home. The slops from the wards are emptied into tanks on wheels and are disposed of outside the hospital grounds. The dry refuse is also taken outside the hospital grounds, where it is burnt and then buried.

The linen is washed at the Pretoria Steam Laundry. All infected articles are disinfected at the hospital in a Thresh's steam steriliser, the soiled articles being first soaked in a solution of izal.

Up to the present date (Dec. 27th, 1900) over 2000 patients, including 200 officers, have been treated in this hospital. Patients from a distance arrive either in convoys or in hospital trains. The railway siding is about half a mile from the hospital, whither the patients are conveyed in our own ambulances. Patients from Pretoria and its immediate neighbourhood come either in ambulances or in Indian dhoolies carried by native bearers. The majority of our patients are acute cases, inasmuch as there is accommodation for convalescent patients in the Yeomanry and in the convalescent camps.

The medical cases consist principally of enteric fever, dysentery, and malaria. In Pretoria itself malaria does not appear to occur, but to the north in the bush veldt, to the west in the Rustenburg district, and along the eastern line towards Komati Poort it is very prevalent. On Nov. 20th 32 cases of malaria all contracted within a few days were admitted from the Rustenberg district. The enteric fever cases came from various parts; a noticeable feature has been the tendency to fatal cardiac failure in cases which would otherwise not be especially severe. A similar observation was made at the Deelfontein Hospital in patients who had been exposed to excessive fatigue previously to being attacked with the disease. In addition to malaria and enteric fever there have been a number of cases of indefinite pyrexia which go under the much-abused name of "simple continued fever." Some of these cases are cases of influenza, but others appear to belong to some undetermined fever. Dr. G. Turner, the medical officer of health of the Transvaal Colony, has started a compulsory notification of infective diseases similar to that in force at home, which will no doubt be of value in tracing these diseases to their origin.

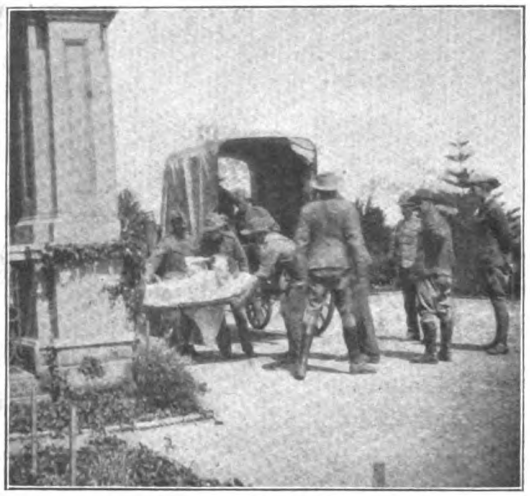
The surgical work of the hospital has naturally depended upon the locality of the fighting. During the earlier days of the hospital the fighting round Pretoria was desultory and the casualties were few, and except for the occasional arrival of a convoy from Rustenburg or some other outlying district the cases were similiar to those found in a civil hospital at home. Our operations included several for the radical cure of hernia and

FIG. 3.

Medical and Nursing Staff of the Imperial Yeomanry Hospital at Pretoria.

varicocele, two for the removal of the vermiform appendix, cases of nerve suture, a few amputations, and many cases of severe hæmorrhoids. In addition to these there have always been, even at the beginning, a certain number of cases of gunshot wounds. Surgical complications in the dysentery and enteric fever cases have been very few, operative treatment having only been called for three times, once for perforation of a dysenteric ulcer, once for amputation of a gangrenous leg due to arteritis occurring in enteric fever, and once for trephining the mastoid antrum in a case of middle-ear complication due to the same cause. During the last few weeks, however, the character of the work has entirely changed and the surgical resources of the hospital have been taxed to their utmost limit by the number and severity of the gunshot wounds which have been brought in. For instance, on Dec. 3rd 10 wounded officers and 27 wounded men were admitted from the fight at Rhenoster Kop (Fig. 4). Most of the men belonged to the New

FIG. 4.



Arrival at hospital of patients of General Paget's column after the fight at Rhenoster Kop.

Zealand contingent, and among the officers was Dr. Chalice, a civil surgeon, who was severely wounded in the thigh and who had behaved with conspicuous gallantry. On Dec. 18th six wounded officers and 11 wounded men were admitted from Clements's Brigade at Rietfontein, and on the 21st 10 more wounded men were admitted from the same force. To-day a convoy of 25 wounded men and one officer have arrived from the Yeomanry Field Hospital at Rietfontein. All varieties of injuries have been represented both with regard to the locality of the wound and the nature of the projectile causing it. Speaking in general terms our experience has been that wounds out here heal more rapidly and satisfactorily than those seen in civil practice at home. Suppuration is rare provided early attention is given to the wounded.

Various amusements are provided for the patients. Visitors are admitted on three afternoons a week or at any time by special permission of the commandant. The band of the 2nd Lincoln Regiment, by the kind permission of Major Day, plays in the hospital grounds every Saturday afternoon, and these occasions are eagerly looked forward to by the patients. A small theatre constructed of three tents has been erected on the tennis lawn and is used for occasional concerts and for a small play which is being prepared for New Year's Eve.

December 30th, 1900.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6018 births and 3707 deaths were registered during the week ending Feb. 2nd. The annual rate of mortality in these towns, which had been 19·6, 19·1, and 17·9 per 1000 in the three preceding weeks, further declined last week to 16·4. In London the death-rate was 16·1 per 1000, while it averaged 16·6 in the 32 large provincial towns. The lowest death-rates in these towns were 10·0 in Burnley, 10·2 in Leicester, 11·8 in Cardiff, and 11·9 in Derby and in West Ham; the highest rates were 19·6 in Manchester and in Wolverhampton, 21·9 in Liverpool, 24·1 in Gateshead, and 26·4 in Norwich. The 3707 deaths in these towns included 323 which were referred to the principal zymotic diseases, against 389, 374, and 347 in the three preceding weeks; of these 104 resulted from whooping-cough, 69 from diphtheria, 56 from measles, 33 from "fever" (principally enteric), 30 from scarlet fever, 30 from diarrhœal diseases, and one from small-pox. No death from any of these diseases occurred last week in Plymouth or in Huddersfield; in the other towns they caused the lowest death-rates in Croydon, Portsmouth, Norwich, Bolton, and Burnley, and the highest rates in Nottingham, Birkenhead, Liverpool, and Salford. The greatest mortality from measles occurred in Liverpool and Sunderland; from scarlet fever in Salford; and from whooping-cough in Wolverhampton, Nottingham, and Birkenhead. The mortality from "fever" showed no marked excess in any of the large towns. The 69 deaths from diphtheria included 24 in London, eight in Sheffield, six in Liverpool, and five in Leeds. One fatal case of small-pox was registered in Newcastle, but not one in any other of the 33 large towns; three small-pox patients remained under treatment in the Metropolitan Asylums hospitals on Saturday last, Feb. 2nd, and one new case was admitted during the week. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2037, against numbers decreasing from 2535 to 2078 on the five preceding Saturdays; 178 new cases were admitted during the week, against 156, 187, and 172 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 422 and 394 in the two preceding weeks, further declined last week to 323, and were 144 below the average. Influenza was certified as the primary cause of 15 deaths in London last week, against 20 and 17 in the two preceding weeks. The causes of 51, or 1·4 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Cardiff, Nottingham, Bradford, Leeds, and in 10 other smaller towns; the largest proportions of uncertified deaths were registered in Leicester, Halifax, Sheffield, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 24·0 and 21·1 per 1000 in the two preceding weeks, rose again to 22·2 during the week ending Feb. 2nd, and showed an excess of 5·8 per 1000 over the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 17·6 in Leith and 20·2 in Paisley and in Perth, to 23·5 in Glasgow and 23·6 in Aberdeen. The 695 deaths in these towns included 43 which were referred to whooping-cough, 27 to diarrhœa, 24 to small-pox, 16 to measles, seven to diphtheria, six to "fever," and three to scarlet fever. In all, 126 deaths resulted from these principal zymotic diseases, against 125 and 106 in the two preceding weeks. These 126 deaths were equal to an annual rate of 4·0 per 1000, which was 2·4 per 1000 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping-cough, which had been 61 and 39 in the two preceding weeks, rose again last week to 43, and included 34 in Glasgow, three in Edinburgh, two in Dundee, and two in Paisley. The deaths from diarrhœa, which had been 22, 16, and 15 in the three preceding weeks, rose again last week to 27, of which 21 occurred in Glasgow and three in Edinburgh. The fatal cases of small-pox, which had been two, three, and 11 in the three preceding weeks, further rose last week to 24, and were all recorded in Glasgow. The deaths from measles, which had been 23 and 18 in the two preceding weeks, declined again last week to 16, of which eight occurred in Edinburgh and four in Aberdeen. The fatal cases of diphtheria, which had been six and eight in the two preceding weeks, declined again to seven last week, and included three in Glasgow. The deaths resulting from different forms of "fever," which had been two, 14, and 15 in the three preceding weeks, declined again last week to six, of which five were registered in Glasgow. The

deaths referred to diseases of the respiratory organs in these towns, which had risen from 105 to 145 in the four preceding weeks, declined again last week to 123, and were 89 below the number in the corresponding period of last year. The causes of 35, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 30·4 and 28·2 per 1000 in the two preceding weeks, further declined to 27·4 during the week ending Feb. 2nd. During the past four weeks the death-rate in the city has averaged 28·6 per 1000, the rates during the same period being 18·0 in London and 21·5 in Edinburgh. The 182 deaths belonging to Dublin registered during the week under notice were 5 less than the number in the preceding week and included 18 which were referred to the principal zymotic diseases, against 16 and 20 in the two preceding weeks; of these, 12 resulted from whooping-cough, three from "fever," two from diarrhœa, and one from diphtheria. These 18 deaths were equal to an annual rate of 2·7 per 1000, the zymotic death-rate during the same period being 1·4 in London and 2·7 in Edinburgh. The deaths referred to whooping-cough, which had been 10, 12, and 8 in the three preceding weeks, rose again to 12 last week. The fatal cases of "fever," which had been three, three, and six in the three preceding weeks, declined again last week to three. The 182 deaths in Dublin last week included 29 of children under one year of age and 44 of persons aged upwards of 60 years; the deaths of infants showed a slight decline, while those of elderly persons were considerably less than the number in the preceding week. Seven inquest cases and seven deaths from violence were registered during the week; and 63 or more than a third, of the deaths occurred in public institutions. The causes of nine, or nearly 5 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL ARMY MEDICAL CORPS.

Captain C. T. Samman has joined at Woolwich. Lieutenants A. J. McN. Cuddon-Fletcher and A. D. Jameson proceed to Aldershot for a course of instruction at the Depôt, R.A.M.C., returning to Woolwich on the completion of the course. Major Berryman is in medical charge of the *Formosa* taking troops to Malta and Egypt. Civil Surgeon J. Freeman has assumed medical charge of the troops at Plymouth, vice Lieutenant-Colonel Turner, who is granted temporary leave of absence.

SOUTH AFRICAN NOTES.

Civil Surgeon S. Sharp has been discharged from hospital to duty.

VOLUNTEER MEDICAL ASSOCIATION.

The monthly council meeting of this association was held at the head-quarters, 20, Hanover-square, on Jan. 29th, Brigade-Surgeon-Lieutenant-Colonel Andrew Clark, V.D., being in the chair. There were present Brigade-Surgeon-Lieutenant-Colonel H. G. Thompson and Brigade-Surgeon-Lieutenant-Colonel P. B. Giles, V.D., Surgeon-Lieutenant-Colonel M. Baines, V.D. (retired), Surgeon-Lieutenant-Colonel J. Edward Squire, V.D., Surgeon-Major V. Matthews, Surgeon-Major W. Culver James, Surgeon-Captain J. Harper, Surgeon-Captain W. A. Dingle, Surgeon-Captain T. H. Dickson, Surgeon-Captain J. Cantlie, (honorary treasurer), and Surgeon-Major I. I. de Z. Marshall (honorary secretary). Amongst other business the annual challenge shield competition for this year was dealt with, the recommendations of the sub-committee being adopted—viz.:—

That all notices concerning the challenge shield competition should be sent through the brigade officer by means of a special letter to each brigade, such letter to be directed to the officer commanding the regimental district and accompanied by circulars for each regiment in his command.

That, in order to save time and expense, it is suggested that preliminary competitions should be held in each brigade to select one or more squads for the final competition and that a prize might be offered by each brigade to encourage entries.

It was agreed that the final competition be held in Wellington barracks on the first Saturday in June (the 8th). The annual meeting was fixed to take place after the council meeting on the last Tuesday in April (the 30th). The following report of a sub-committee, moved for by Surgeon-Major V. Matthews to consider the effect of the new Volunteer Act, 1900, upon volunteer medical officers, was adopted:—

That the attention of the proper authorities be called to the possible effect of the Volunteer Act, 1900, pressing unduly on volunteer medical officers, as it may necessitate their throwing up their practices if they are liable to compulsory service at long distances from their homes, as, owing to the shortness of the medical department of the regular army the volunteer medical services would, in all probability, be called out first and released the last.

It was resolved that a letter embodying the resolution be written to the Secretary of State for War. The following vote of condolence to His Majesty the King, proposed by Surgeon-Lieutenant-Colonel J. E. Squire, and seconded by Surgeon-Major W. Culver James, was carried unanimously, and was directed to be forwarded through the Secretary of State for the Home Department:—

The Council of the Volunteer Medical Association beg with all respect to offer to His Majesty the King, who as Prince of Wales was president of the association, their condolence on the irreparable loss sustained by His Majesty and by the whole empire, on the death of Her Most Gracious Majesty Queen Victoria.

GALLANTRY OF A FRENCH MEDICAL OFFICER.

According to a recent Ministerial decision Dr. Henri Mathé of the French navy has been granted special promotion on account of his meritorious services while on duty at Dakar in Senegal. The official announcement says that Dr. Mathé particularly distinguished himself by displaying exceptional qualities of initiative intelligence and devotion during an epidemic of yellow fever. "Left the only officer at the station by the demise of the commandant and his combatant staff he immediately assumed, with as much decision as coolness, the whole of the responsibilities inherent to such a situation."

THE INDIAN CONTINGENT IN CHINA.

The expeditionary force of native troops and followers sent from India to China was provided with a very liberal supply of warm clothing and it is satisfactory to find that although pneumonia has appeared among them the mortality has so far been comparatively small. It is well known that the natives of India when employed on field service during the cold season are much more susceptible to pneumonia and pulmonary disease than European troops.

Among the floral tributes received at Windsor Castle was a wreath of white flowers from the sick and wounded in the Royal Victoria Hospital, Netley. The card bore this inscription: "In affectionate remembrance of our beloved Queen from the sick and wounded soldiers at the Royal Victoria Hospital." A superb crown of white flowers with an appropriate inscription was also sent by Colonel Charlton and the military officers of the hospital. A wreath had previously been sent to Osborne House by Miss H. Norman, R.R.C., lady superintendent, and the nursing sisters at Netley.

Among the military officers who formed part of the procession from Osborne to the Royal yacht were numbered Colonel W. J. Charlton, R.A.M.C., principal medical officer of the Royal Victoria Hospital, Netley, and Major Treherne, R.A.M.C., his staff officer.

According to the *Pioneer Mail* of Jan. 11th it is reported that the 2nd Battalion, Durham Light Infantry, are to be moved from Burma to Wellington, pending their departure home with a view to an improvement of the state of health of the regiment. The 1st Battalion, Royal Fusiliers, at Nasirabad will proceed to Burma.

"Audi alteram partem."

THE SOUTH AFRICAN HOSPITALS COMMISSION.

To the Editors of THE LANCET.

SIRS,—Considering the circumstances which surrounded the birth of this Commission—the essentially technical character of the inquiry as originally proposed, the tergiversation of the Government on its composition and scope, its subsequent extension on both headings, the tone of some of the speeches in the House of Commons, the animus against medical men and the absence upon it of any member with knowledge of

the service, its regulations and requirements, to which you draw attention in the leading article in THE LANCET of Feb. 2nd, p. 338—the Royal Army Medical Corps may rest thankful for the lines on which this inquiry has been carried out, for the impartiality shown, and for the conclusions arrived at. Tersely put it may be said that the defects brought to light touching the well-being of the sick and wounded range themselves under imperfections in the organisation of the corps and deficiency of materials, the exigencies of war and the absence of sufficient transport; and, in respect to the first, quite preventable, it is abundantly clear that the responsibility rests with the sections of the War Office concerned with the points in question. And when we note the nature of the defects shown in the field under the pressure of military operations we recognise how closely they fit in with the known imperfections under which the corps laboured during peace and from which those having practical experience feared the results which have followed. A corps reduced to a numerical strength not even sufficient for peace requirements, with, so far as our officers were concerned, a *paper* reserve, deprived of all stimulus towards personal efficiency and professional progress, with deficient material to work with and practically no opportunities for practising during peace the demands of war, necessarily was unable to meet the onerous burden of a large war, yet showed the value of its component parts and the ability and energy of the majority of its *personnel* as, when supplemented by a strong civil contingent of officers and men and by private help, allowed the Commission to conclude that "it cannot be properly said that the medical and hospital arrangements have broken down; there has been nothing in the nature of a scandal with regard to the care of the sick and wounded, no general or wide-spread neglect of patients or indifference to their sufferings, and all witnesses of experience in other wars are practically unanimous in the view that taking it all in all in no campaign have the sick and wounded been so well looked after as they have been in this." One bubble which has been pricked is the asserted existence of an army reserve of medical men in the auxiliary forces or otherwise, and another, apparently relied on by the military coterie, is the hitherto asserted competency of the civil section adequately to take the place of a trained army medical staff.

To enter further into details would occupy too much of your valuable space. Suffice it to say, that the business-like recommendations of the Commission even better emphasise the defects elucidated than the narration of the work undertaken; while on the three main points of the desirability of the conditions of service being such as to draw good professional men and ensure the maintenance of their qualifications at a high level, advancement for merit rather than by seniority for the upper ranks, and the production of good sanitarians in the Royal Army Medical Corps, they do but repeat the recommendations of the Crimean inquiry, and so land us exactly where we then were, with the whole of the sad experience then culled and the good intentions then formulated wasted and annulled in the interval by those to whom the well-being and efficiency of the medical section of army work was entrusted. In point of fact, the nation is again asked to do in 1901 what it was asked to do in 1858, what with the best intentions it proposed to do, but which it utterly failed to bring to good effect through its negligence to watch over the acts of its officials; and the pressing present question is, Will it do any better now and in the future?

The Commission merely indicate the lines along which progress should run and suggest another committee—departmental or otherwise—to formulate the necessary details, and hence its accomplished work is but the primary step in the scheme to be evolved. It is apparent that the composition of this committee is all important, as with it rest the power of laying down the measures essential towards giving due effect to the recommendations made or, on the other hand, frustrating the attempt now again made to evolve an efficient medical corps capable of doing the highly important duties entrusted to it—duties now clearly placed before the public and after this committee has drawn up a course of action calculated to effect the objects desired it will rest with the War Minister to embody this outcome in a royal warrant or otherwise. And this third step satisfactorily accomplished the crux of the scheme, the pivot on which the entire previous labours will turn for good or evil results, will be arrived at as embodied in the questions: What guarantee have we that the decisions arrived at will be respected and not whittled away or ignored as in the past? Where resides the power capable of giving full effect to them?

The unfortunate position of the Royal Army Medical Corps is that it is dependent for good working on so many sections of the War Office, any one or all of which may adversely influence it; and what is wanted is an emancipation of the corps from these trammels so that it may be free to perfect itself in accordance with its known wants from a professional standpoint and on a business basis. Clearly, much remains to be done before a successful issue is arrived at.

I am, Sirs, yours faithfully,

[redacted]

FRANCIS H. WELCH, F.R.C.S. Eng.,
Surgeon-Colonel (retired), Medical Staff.

Brandram-road, Lee, Feb. 4th, 1901.

"SELENIUM COMPOUNDS AS FACTORS IN THE RECENT BEER-POISONING EPIDEMIC."

To the Editors of THE LANCET.

SIRS,—Since the publication of our last note[1] upon this subject we have continued our work in this direction, and have been able to demonstrate the presence of selenium in brewing sugar and beer, the only source of which is the impure sulphuric acid used in the manufacture of the sugar. The brewing sugar in addition to selenium contained arsenic. We may say incidentally that this sugar was not manufactured by the firm implicated in the recent epidemic. The beer we examined we obtained through the kindness of Sir Lauder Brunton, and it was one which was undoubtedly concerned in the beer-poisoning epidemic. We are at present occupied in the quantitative estimation of the selenium in both these substances.

With regard to the pharmacological action of selenious acid the recent results obtained by O. Modica[2] are of especial interest in this connexion. This observer, while confirming the results of Czapek and Weil[3] concerning the similarity of arsenious and selenious acid with regard to acute poisoning, points out that the symptoms of chronic poisoning which they produce are not by any means so similar. For instance, whilst wasting in animals chronically poisoned by arsenic practically never occurs, in chronic selenious acid poisoning it is never absent. Further, in animals tolerance to continued small doses of arsenic is easily obtained. This is not so in the case of selenious acid.

We are, Sirs, yours faithfully,

F. W. TUNNICLIFFE, M.D., M.R.C.P. Lond.,
Professor of Materia Medica and Pharmacology in King's College, London),
OTTO ROSENHEIM, Ph.D., F.C.S.

King's College, London.

THE ADAPTABILITY OF CLOVER'S INHALER.

To the Editors of THE LANCET.

SIRS,—This well-known inhaler has, with slight modifications, held its own for many years in the administration of ether and when fitted with a tap at the free end of the bag is frequently used for giving nitrous oxide prior to etherisation. It does not appear to be generally known that a Clover's inhaler *without the bag* is safe and effective for administration of chloroform or of mixtures of chloroform and ether. (Chloroform pure or in a mixture must never be given with the bag on, as this is practically a closed method, and to give chloroform by such a method is simply tempting Providence.) Within the last few years McArdle has drawn attention to the utility of this method in giving Tait's mixture, which consists of chloroform one part and ether two parts, for gynæcological work. With slight modifications in the method of administration, I find it equally useful for administration of chloroform alone and other mixtures of chloroform and ether. The following mixtures are of service:—

	Chloroform.	Ether.
For a healthy man	2 parts	1 part
For a feeble man	1 part	1 part
For women and children	1 part	2 parts (Tait's mixture).

The chloroform and ether are best kept in separate bottles

[1] THE LANCET, Feb. 2nd, 1901, p. 318.
[2] Archiv. Farm. e Terap., Palermo, vol. v., 1897, p. 61.
[3] Archiv für Experimentelle Pathologie und Pharmacologie, xxxii., 1893.

and the mixture measured out as required. In giving chloroform alone I start with one ounce of the anæsthetic in the chamber and with the indicator at 0. After a few breaths the indicator is gradually moved to midway between 0 and 1 and then slowly and by regular gradations advanced up to 3. This occupies five or six minutes. The indicator is then kept at 3 until complete anæsthesia is induced, generally in another four or five minutes, and for the rest of the administration it is moved back and kept between 1½ and 2 as may be found necessary. In giving mixtures of chloroform and ether one and a half ounces of the mixture are poured into the chamber and the same method holds good, except that to induce anæsthesia the indicator must be advanced to Full and after production of complete anæsthesia kept between 2 and 3. The greater the proportion of ether in the mixture the nearer will the indicator have to be kept to 3. Mixtures of chloroform and ether require from 10 to 12 minutes for production of complete anæsthesia. Having the anæsthetic in a reservoir which has to be replenished about twice in the hour is very superior to the constant bottle-tilting or ball-squeezing which is inseparable from the open and Junker methods and is very readily appreciated by anyone who has often to administer anæsthetics for three or four hours on end. The same precautions and the same watch on the pulse, respiration, and pupil are necessary in this as in any other method of administration. I have practically given up the dropping on lint method for the Clover's inhaler without the bag, except in those operations on the face or mouth which would foul the interior of the Clover's inhaler with blood. There is a great advantage in a simple apparatus which can be used equally well for nitrous oxide, ether, nitrous oxide and ether, chloroform, and chloroform and ether mixed.

I am, Sirs, yours faithfully,

C. HAMILTON WHITEFORD, M.R.C.S.Eng., L.R.C.P.Lond.,
Hon. Anæsthetist to the South Devon and East Cornwall Hospital.

Plymouth, Feb. 4th, 1901.

"WHAT IS 'COGNAC BRANDY'?"

To the Editors of THE LANCET.

SIRS,—My attention has been directed to a joint letter of Messrs. Hennessy and Martell which appeared in THE LANCET of Feb. 2nd, p. 358, relating to an action in which my company is concerned and to my evidence therein. The report of the case in the Dublin journals upon which Messrs. Hennessy and Martell's letter is based was incomplete and in material respects inaccurate. No shorthand writer was available at the hearing to take a verbatim note. As the case is under appeal I refrain from discussing its merits and will only at present deal with certain facts given in evidence so far as rendered necessary by the letter you have inserted.

It was stated in evidence that my company's predecessors sold and invoiced the brandy in question at 42*s.*, not as "cognac" but merely as "brandy." The plaintiff's counsel, in spite of three distinct suggestions by the Lord Chief Justice, refused to amend his pleadings in this sense and insisted that "brandy" necessarily meant "cognac" (ignoring the existence of Australian, Californian, Spanish, and other brandies), and further insisted that brandy must be exclusively the produce grown in the commune of Cognac. In my evidence I stated that pure cognac should be the produce of the two Charentes, but plaintiff's counsel insisted upon his limitation, and I therefore, in the "lamentable ignorance" referred to by your two correspondents, did state—and I adhere to the statement—that brandy made exclusively from grapes of the commune of Cognac did not exist on the market. Messrs. Hennessy's and Martell's names were not introduced by me into the case, but when asked specifically I did state that at equal prices the brandies of all cognac shippers, including those of the two firms named, were practically made in the same manner. That statement was not intended, and I submit is not calculated, to reflect upon them, and I should be sorry if it were considered otherwise.

Passing from the personal part of the matter to the larger question, namely, the interest of the British public—in which the named firms stated that they addressed you—may I be permitted to state that I visited the two Charentes before and since the destruction of the vineyards by the phylloxera and claim to have, in spite of the suggested "lamentable ignorance," not only a knowledge of the Cognac district, but also of its products as shipped before and since the stated period. I concur that last year the Charentes have produced—for the first time in 22 years—cognac in appreciable quantities. Your correspondents are silent as to the failure of such production during the preceding 22 years; they point out that there is "now" offered on the market Cognac brandy of the last vintage at prices less than those of the ante-phylloxera period, but do they suggest that the brandy of the last vintage—made a few months ago—is now offered to, or available to, the public for present consumption? Your correspondents are also silent as to the large quantities of brandy shipped from the Charente during the 22 years succeeding 1878—the year of the devastation of the vineyards—until last year's bountiful vintage. I have it on the authority of eminent cognac shippers that the production of wine in the Charente in 1877 was about 15 000 000 hectolitres; that in 1878, when the vineyards were generally attacked, the yield was reduced to about 6,000,000 hectolitres; that in 1879 and 1880 there was a further reduction; and that between and including the years 1881 to 1890 the yield was insignificant. Yet in 1879, the year following the destruction of the vineyards, there was a record exportation of brandy from Charente—viz., some 500,000 hectolitres—which doubtless consisted largely of old stocks; but it is curious that during the years 1881 to 1890 when the yield was insignificant the exportation did not materially decrease, being about 300 000 hectolitres annually. It is significant that during that period and since large quantities of spirits from other parts have been imported into the Charente, and at the trade auction sales in London for a number of years large quantities of brandy shipped from the Charente were sold as to the greater part from 25 to 75 per cent. less than the prices quoted by Messrs. Hennessy and Martell for the new vintage of last year, in fact as low as 1*s.* 8*d.* per gallon. Putting aside the new brandy of last year's vintage, are the brandies shipped as stated from the Charente during the last 22 years, even as to a moderate proportion, the "good and pure cognac available at moderate prices" referred to by your correspondents?

I am in complete sympathy with the ostensible objects of the syndicate recently formed in the Charente for the protection of "cognac." It is to be hoped that the syndicate will ensure that what is shipped from the Charentes as "cognac" contains no spirit other than that produced from grapes of the Charente, and that if such is blended with any other spirit the product is not shipped as "cognac." I stated in my evidence that pure cognac of a suitable age for present consumption—not last year's vintage—and without any admixture of other spirit cannot at present be obtained under a comparatively high price, and I consider that it is in the interest of the public as well as in that of shippers of genuine cognac that this fact should be well understood.

In asking you in fairness to my company to insert this letter I apologise for trespassing at such length on your valuable space and—Remain, Sirs, yours faithfully,

F. B. EHRMANN,
Managing Director, Ehrmann Bros., Ltd.

Finsbury-square, London, E.C., Feb. 4th, 1901.

THE RÔLE OF ARSENIC IN THE RECENT EPIDEMIC OF PERIPHERAL NEURITIS.

To the Editors of THE LANCET.

SIRS,—With regard to a paragraph in a leading article in THE LANCET of Feb. 2nd, p. 341, in which you suggest the possibility of the rôle played by arsenic in the recent epidemic of peripheral neuritis being challenged, may we be permitted to draw your attention to our articles in the *British Medical Journal* of Dec. 1st and 8th, to Major Ronald Ross's letter in THE LANCET of Dec 8th, 1900, p. 1677, and to Dr. Prytherch's remarks at a meeting of the Liverpool Medical Society, as reported by you in THE LANCET of Jan. 5th, 1901, p. 33? We have from the first opposed the idea of the wholesale poisoning by arsenic and our opinions are not modified in the least degree. With apologies for troubling you,

We are, Sirs, yours faithfully,

W. A. NEWALL
J. R. PRYTHERCH.

Chester, Feb. 5th, 1901.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Increase of the Plague.

THE feature of the week has been the marked development of the plague epidemic in Bombay city and the evident signs of a recrudescence in the sister city of Calcutta. For the whole of India during the week ending Jan. 5th there were 2453 deaths from plague, compared with 2298 during the previous seven days, and with 1386 during the corresponding week of last year. In Bengal there was an increase from 1374 to 1500. There were 414 deaths from plague in Mysore, 261 deaths in the Bombay Presidency, 171 in Bombay city, 67 in Calcutta, 25 in the Madras Presidency, 14 in the Hyderabad State, and 11 in the Punjab. In Bombay City the increase was from 982 to 1119. In Bengal the Patna district returned 821 deaths, Sarun district 385, Monghyr 194, Gaya 99, and Howrah one. The increase in Calcutta is greater than the figures show, partly because a much larger proportion of deaths have during the past week been returned as due to plague (whereas previously so-called suspected deaths formed a greater portion of the total figures), and partly because there is probably more plague than is officially reported.

Greater effort should be made to popularise inoculation in Calcutta. The operation is accepted in the other plague affected districts of Bengal under the influence of Major Sunder, I.M.S. In the Punjab it has been vigorously pushed and apparently with great success. The prophylactic is not being sought for much at the present time in Bombay City, notwithstanding the threatened outbreak, but a very large number of inoculations have been already done there.

The hospital ship *Gwalior*, after some additional medical fittings, will sail again for China, probably about the 30th.

There is no further diminution in the famine returns; indeed, in some places there is a slight increase.

Jan. 12th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Death of the Queen.

MATTERS of local interest have lately given place to the all-absorbing details connected with the lamented death of Queen Victoria. Loyalty and devotion to her memory have been displayed widely in profound grief and universal mourning. The late Queen was patron of the Queen's Hospital. Her interest was also generously shown by the opening of the Jaffray Hospital by the Prince of Wales and of the laying of the foundation-stone of the General Hospital by the Duke of York as her representatives. Her Majesty in her own person laid the foundation-stone of the law courts which bear her name in this city. On Jan. 10th only a statue of Her Majesty—the gift of a Birmingham citizen, Mr. Barker—was unveiled in the centre of the town amid the acclamation of a large crowd. The enthusiasm of this tribute to the celebration of her Diamond Jubilee had hardly died away when the news of her illness and unexpected death reached our ears. Ere the echo of rejoicing had died away there came the sound of lamentation and a sense of profound sorrow. Happily this was mingled with national pride in our Queen's long and glorious career, the record of which will remain in history as an example of a monarch whose life was devoted to the interests and welfare of her people.

Walter Myers, B.Sc. Lond., M.A., M.B. Cantab.

Dr. Myers, whose life has been yielded to the cause of science in a sad manner, was a Birmingham student who after obtaining high academic distinction was selected by the Liverpool College to go abroad for the purpose of studying tropical diseases. At Parà he contracted yellow fever, to which he succumbed. At Cambridge he obtained a natural science scholarship at Caius College and after a distinguished career took the degrees of Master in Arts and Bachelor in Medicine. Ardent and devoted to his studies, painstaking and accurate in his observations, with prospects of a brilliant course open to him, he fell a martyr to progress. Much sympathy is felt in the city for his parents, of whom he was an only son.

The Hospital for Sick Children.

The fortieth annual meeting of the governors and subscribers to this institution was held on Jan. 28th, under the presidency of the Lord Mayor (Alderman Edwards). The report read was a very satisfactory one. The number of patients treated last year was 14,829, of whom 13,535 were out-patients, and the death-rate was 7·9 per cent. As usual, the committee deplored a deficiency in the balance-sheet, the income falling short of the expenditure by £590. The new operating theatre and reception rooms have been finished and already have proved an inestimable advantage.

The Prosecution of Druggists.

At the police-court on Jan. 18th a local firm of druggists were heavily fined. One summons was for selling tincture of benzoin which was not of the nature, substance, and quality demanded, and another was for selling camphorated oil which only contained 78 per cent. of the quantity of camphor contained in camphorated oil prepared according to the British Pharmacopœia. As usual, much conflicting evidence was adduced, and the question of employing unqualified assistants to dispense was brought to the front. After some strong remarks from the bench a fine of £20 and costs was inflicted in each case.

Feb. 5th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Magisterial Decisions in Cases arising out of Arsenic Poisoning by Beer.

TWO decisions given by the stipendiary magistrates at the city and county police-courts a few days ago are distinctly opposed to each other. At the Manchester City Police-court Mr. Headlam said the defendant was "summoned for selling beer to the prejudice of the purchaser, such beer not being of the nature, substance, and quality of the thing demanded." This was under the sixth section of the Sale of Food and Drugs Act. The beer contained arsenic. Mr. Moulton had argued that arsenic being an ingredient injurious to health the summons should have been taken out under the third section, the article sold being really beer into which, through no fault and without the knowledge of the defendant, arsenic had been introduced. But a summons under the third section must have failed because knowledge of the fact on the part of the vendor is essential to a conviction. But Mr. Headlam was of opinion that the defendant could be convicted under the sixth section, which was passed in the interests of the purchaser, "and it is not required that the vendor should have knowledge of any adulteration in the article purchased." The vendor can, however, protect himself by obtaining a warranty from the person who supplies him with the article. He said that it would be an extraordinary thing that a person who unknowingly sells milk with water in it should be liable to a penalty, while one "who unknowingly sells beer with arsenic in it should be allowed to go free." He convicted the defendant and imposed a fine of 40*s*. An appeal was allowed. At the Manchester County Police-court Mr. J. M. Yates, K.C., the stipendiary magistrate, in a similar case gave an opposite decision. He said that beer containing arsenic had been purchased from the defendant and the quantity was admittedly such as to be prejudicial to health. A summons was taken out under the Sale of Food and Drugs Act, 1875, Section 6. For the defendant it was contended that Section 6 did not apply, but that proceedings should have been taken under Section 3. It was proved that he was ignorant of the adulteration, that he could not with reasonable diligence have ascertained it, and that he had no reason or grounds for suspicion. But Section 3 supposes knowledge of the adulteration, so that defendant could not be convicted under that section. Section 5 provides that the seller of the article of food is not liable to conviction if he sells in ignorance of the adulteration and could not with reasonable diligence have obtained the knowledge. Here, again, the facts show that under this section the defendant ought not to be convicted. It was contended that he was liable to conviction under the sixth section, which is that "no person shall sell to the prejudice of the purchaser any article of food which is not of the nature, substance, and quality of the article demanded, &c." But the defence to this is given by the twenty-fifth section, that he sold the article as he bought it and that he had a

written warranty that it was of the nature, substance, and quality of the article demanded. Mr. Yates thinks that the legislature intended to make a difference between an adulteration of a harmless nature, as of milk with water or the abstraction of cream from milk, and an adulteration with substances prejudicial to health. In the former case an inferior article of food is sold. According to this view Sections 3, 4, and 5 codify the law as to adulteration that is prejudicial to health, and Sections 6, 7, 8, 9, and 25 the law as to adulteration that is other than prejudicial to health. "In this case," he said, "Section 3 mostly applies to the facts in evidence here. ..... Such being my opinion, I dismiss the summons, and I do so more readily as whoever may be to blame the one least of all to blame is the beer retailer." With this last opinion we all probably agree, and so the burden of responsibility is thrown back on the brewer, from him on the manufacturer of glucose and "inverts," and from him to the maker of sulphuric acid. There is to be an appeal in this case as in that before Mr. Headlam. The ultimate decision is important, as each stands for many others. Possibly learned judges may be able to bring order out of the apparent chaos of the Sale of Food and Drugs Act.

Manchester Royal Infirmary.

At a meeting of the Manchester Infirmary Board on Jan. 28th the chairman, Mr. E. S. Heywood, said that it was the last meeting for which he was appointed to act as chairman. He had held this position for 25 years, but did not wish to be re-elected to it, as he did not feel equal "to the heavy obligations which the duties of the position imposed." Mr. W. I. Crossley expressed the very great regret with which the board had heard Mr. Heywood's decision. His kind manner had endeared him to every member of the board "and the parting would cause a great pang." Mr. Heywood's retirement from the chairmanship of the board will, I am sure, be regretted by every member of the medical staff. Questions have to be considered from time to time which give evidence of differences of opinion between the board and the staff, but through all the discussions and controversies that have arisen the uniform courtesy and kindness and the characteristic fairness of mind which Mr. Heywood has always displayed have done much to render the intercourse between the lay and the medical authorities agreeable and beneficial. It may be hoped that his knowledge of infirmary problems and his wise judgment may long be given to the institution. At the same meeting the board confirmed a recommendation from the House Committee that "as an experiment 'kosher' food for Jewish inpatients should be provided for one year, under such restrictions as might be considered necessary"

Jewish Hospital Scheme.

A public meeting of the subscribers and supporters of the proposed Manchester Jewish Hospital was held on Feb. 3rd. The chairman said that the committee intended to have the name of Victoria, "England's late beloved Queen," connected with the hospital. He said that the concession of the infirmary as to "kosher" meat did not satisfy him and it was evident that it did not satisfy his audience. "Nothing would satisfy them until they had succeeded in establishing in their midst a Jewish hospital for the requirements of a large portion of the community of Manchester." They would require, he said, £6000 to build a hospital with 20 beds, £2000 for equipment, with at least £1500 or perhaps £2000 per year for maintenance. Dr. N. C. Haring moved a resolution to the effect that such a hospital was an "absolute necessity" and pledging the meeting to support the scheme. This view was taken by Dr S. Finklestein who said that Jewish medical men could fill the hospital with cases coming under their notice. The resolution was carried unanimously. Up to the present a sum of £174 has been subscribed, so that the promoters still have the hill before them.

The Ashton Infirmary.

The Ashton-under-Lyne District Infirmary has just received a bequest of £10,000 from the trustees of the late Mr. Holden of Mossley and Oldham. Special privileges are given in the bequest to the borough of Mossley. Part of the money will be appropriated to the establishment of a nurses' home at the infirmary. The Nursing Association's nurses can then go to cases in the surrounding districts, such as Ashton, Stalybridge, and Dukinfield, and live at the home, "whilst six additional nurses could be provided to meet a greatly felt want—viz., to nurse middle-class people who would be willing to pay 15*s.* or 20*s.* per week for their services if they could be spared the inconvenience of maintaining the nurse in the house." These places really form one town, and such a scheme, if found in working to be practicable, would no doubt be a great boon to many who cannot afford the expense of a nurse in the house and who in probably the majority of cases have not the necessary sleeping accommodation to lodge a nurse.

Salford Royal Nurses' Home.

The Salford Royal Nurses' Home, established to commemorate the Diamond Jubilee of our late beloved Queen, was formally opened on Jan. 26th. The advisability of postponing the ceremony had been discussed, but it was decided that it should take place as had been arranged. The movement for its establishment was set on foot by the then mayor, Sir Richard Mottram, in 1897. He was thought too sanguine in expecting to raise the £10,000 required, but it has been done, and as chairman of the committee he has had the satisfaction of being able to hand it over fully equipped for its useful purpose entirely free from debt and without one penny of "chief rent" upon it. The deeds and a letter from the Home Secretary authorising the home to be styled "Royal" were handed by Sir Richard Mottram to Dr. T. Arthur Helme, honorary secretary of the Sick Poor Nursing Institution. Lady Mottram then declared the Home open. In moving a vote of thanks to Lady Mottram, the Bishop of Manchester paid a touching and eloquent tribute to the memory of our late Queen and thought that Lady Mottram in her "labours for the erection of a home for the nurses of the sick poor had been working entirely in harmony with the feelings of the Queen and of the spirit of the age."

Small-pox Hospital for Manchester.

The Sanitary Committee of the corporation recommends the council to propose terms to the Salford Corporation for the purchase of a site in Drinkwater Park, Salford, for the erection of a joint small-pox hospital for Manchester and Salford. It is a difficult, one may say an impossible, task for towns to provide small-pox hospitals without exciting deadly opposition. This scheme will no doubt do so and yet it seems at first sight as little open to objection as any that can be devised and certainly has some advantages over the Carrington Moss scheme.

Feb. 5th.

WALES AND WESTERN COUNTIES

(FROM OUR OWN CORRESPONDENTS.)

A Plague-infected Vessel at Bristol.

THE medical officer of health (Dr. D. S. Davies) of the city of Bristol is fully alive to the possibility of the spread of plague from the s.s. *Rembrandt* upon which plague-stricken rats were recently found. About 100 persons who have been connected in one way or another with the vessel are being daily visited either by Dr. Davies or by his deputy, Mr. J. C. Heaven.

Lampeter Workhouse.

The prosperous condition of the labouring classes at the present time and therefore the absence of able-bodied men and women from the workhouses is significantly shown in a report which the medical officer of the workhouse recently presented to the Lampeter Board of Guardians in which he stated that, excluding the children, all the inmates were suffering more or less from mania, idiocy, imbecility, or hypochondria.

Carmarthen Lunatic Asylum.

The lunatic asylum at Carmarthen serves the three counties of Carmarthenshire, Pembrokeshire, and Cardiganshire, which at the last census had an aggregate population of about 290,000 persons. In his annual report to the joint visiting committee Dr. E. Goodall states that at the end of last year there were 633 patients in the asylum, including 40 private patients. During the year 1900 76 patients died, an increase in the number recorded in previous years, which is said to be due to an epidemic of influenza. The total number of patients admitted during the year was 116, and 16 of these were private patients. The average weekly cost of each patient was 9*s.* 7¼*d.* The visiting committee has decided to engage three additional male attendants and upon their appointment there will be an average of 12 patients to each attendant.

Sanitary Inspectors' Association of South Wales and Monmouthshire.

The Sanitary Inspectors' Association of South Wales and Monmouthshire which was established three years ago held its annual meeting at Aberdare on Jan. 26th. The association has a membership of 105 inspectors and of 74 other persons who are interested in public health matters. The discussion which followed the reading of a paper upon House-to-House Inspection at Aberdare indicated the existence of a full sense of their responsibilities by those who took part in it. Such associations as these ought to do a great deal towards abolishing the nuisance inspector whose office is often a sinecure. That the Local Government Board are anxious to have competent men appointed is well known, and in the case of the appointment of an inspector at Whitland in Carmarthenshire the Board has written to the district council asking for evidence of competency as the testimonials submitted to the Board referred only to character and not to qualification for the position.

Newport and Monmouthshire Hospital.

The financial position of the Newport and Monmouthshire Hospital is in marked contrast to that of many similar institutions. The income—£3041—last year fell short of the expenditure only by £31. There were treated during the year 540 in-patients and 2320 out-patients, and 1268 patients were visited at their homes. It was stated at the annual meeting of the subscribers to the hospital, which was held at Newport on Jan. 31st, that the cost of this home visiting amounted to about £500 yearly, and in view of the fact that in the new building there will be twice as many beds as there are in the present hospital, with a corresponding increase in the expenditure, the directors advised the discontinuance of this branch of the institution. Many subscribers were very much averse to giving up the home visiting, and after some discussion it was ultimately decided that it should be continued only until the opening of the new building. A pleasing feature in the report of the directors was contained in the statement that £1000 had been contributed by the workmen's committee. Three wards in the new hospital are to be completely furnished by Lord Tredegar, Alderman H. J. Davis, the chairman of the board of directors, and Alderman Thomas Jones.

Wage Limit at the Plymouth Royal Eye Infirmary.

The committee of the Plymouth Royal Eye Infirmary recently decided that single men earning more than 18*s.* weekly and married men earning over 30*s.* weekly should be ineligible for treatment at the institution, a plan which could with advantage be followed by other medical charities. The Plymouth District of Oddfellows, however, do not approve of this procedure, for at their annual meeting held on Jan. 28th it was decided to reduce their donation to the infirmary in consequence.

Bath Royal United Hospital.

The annual meeting of the subscribers of the Bath Royal United Hospital was held on Jan. 31st under the presidency of the mayor. The medical report stated that 1384 in-patients were admitted during 1900, against 1289 in 1899. The out-patients numbered 9151, an increase of 210 as compared with the preceding year. The financial statement was unsatisfactory, showing that the deficit of £1100 with which the year 1900 commenced had been increased to £3200. Sanitary improvements in the institution had caused a considerable expenditure. The cost of each bed was estimated at £52 per annum.

Plague in Cardiff.

A case of plague was notified to the Cardiff medical officer of health on Tuesday, Jan. 29th, and the patient, a married man, 38 years of age, died at his own home on the evening of the following Thursday. Dr. W. G. Savage, the bacteriologist to the Cardiff and county public health laboratory, on Tuesday obtained specimens of the patient's blood and after bacteriological examination he was able to report on Thursday morning that the disease was plague. On the same day the culture and fresh material were sent to Dr. Klein who on Sunday confirmed the positive diagnosis of Dr. Savage. Dr. Rees, one of the medical inspectors of the Local Government Board, visited Cardiff on Saturday and Sunday. It is stated that in the vicinity of the works, which are situated near the docks, where the patient was employed a very large number of dead rats have lately been found and that it had been part of his work to collect and destroy the carcasses. When the last case of plague occurred in Cardiff in October last the chairman of the health committee and the medical officer of health were empowered to take any steps they might think desirable for dealing with an outbreak of the disease. They have therefore decided that all men employed in mills or works adjoining the docks shall be medically examined by Dr. Walford who will have the assistance of several other medical practitioners in the town.

Arsenic in Beer at Merthyr.

In the Merthyr Police-court on Feb. 4th the Glamorgan County Council proceeded under Section 6 of the Sale of Food and Drugs Act, 1875, against a publican who had supplied beer which was found to contain one-sixth of a grain of arsenic per gallon. The medical officer of health of Merthyr, Dr. C. E. G. Simons, stated in his evidence that among the workmen employed at the brewery from which the beer was supplied there had been several cases of arsenical poisoning. The stipendiary magistrate imposed a fine of £5 and ordered the defendant to pay the costs.

Feb. 5th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Small-pox in Glasgow.

ABOUT the middle of last week there seemed some reason to believe that the epidemic of small-pox had spent its force, but more recent reports contradict this hopeful anticipation. On Feb. 2nd it was announced that 16 new cases had been admitted to hospital, three had been dismissed, and one had terminated fatally. The number of patients then under treatment was 407. The report on Feb. 4th shows 21 new cases and two dismissals, making the present total 428. In his official report to the corporation Dr. A. K. Chalmers attributes the rapid extension of the disease to the free movement of mild and unrecognised cases which would so easily and extensively occur during the holiday season. In the period from Jan. 13th to 21st, 256 persons were attacked with the disease, this great epidemic virulence corresponding with an added incubation stage of from 10 to 14 days to the opportunities for exposure afforded by the New Year holidays. A further factor is the insufficient vaccination of large sections of the population. As far back as June last the health committee, in view of the then distribution of small-pox, issued a recommendation advising revaccination and offered to pay a fee to practitioners for every case. This advice, however, fell for the most part on heedless ears. Dr. Chalmers considers that, whilst the rush of cases created by the holiday period has passed, a secondary increase of cases is likely to occur at a period corresponding to infection on Jan. 17th, the day on which the maximum amount of infection is known to have been present among the population. In connexion with the subject of revaccination the medical officer draws attention to the fact that during the epidemic the members of the Postal Service, who have necessarily been brought into contact with the infected areas and who are all compulsorily revaccinated, have enjoyed complete exemption from the disease.

Glasgow Maternity Hospital.

The annual report for the past year shows a considerable increase in the work of the hospital and it is becoming evident that the directors will ere long have to face a demand for increased accommodation. Last year the experiment was tried of adding two ladies to the directorate and it is now reported that the result has been a singularly happy one. During the year 116 medical students were enrolled and 42 nurses received a training in obstetric nursing. Dr. Alexander Robertson, who has for many years been one of the most active directors of the hospital, has intimated his resignation. Dr. J. M. Munro Kerr has been appointed one of the obstetric physicians to the hospital and Dr. A. W. Russell one of the assistant obstetric physicians.

Glasgow Eye Infirmary.

The annual meeting of the contributors to the infirmary was held on Jan. 31st. Sir James King, Bart., in moving the adoption of the report, referred to the resignation of the senior surgeon, Dr. Thomas Reid, who has for nearly 40 years been a member of the hospital staff. On behalf of the directors he expressed a very hearty appreciation of Dr. Reid's services, and cordial good wishes for his happiness and welfare. The in-patients admitted during the year

numbered 1448 and the out-patients 18,478. From the report it appears that in 149 cases an eye was removed; in three of these the operation was demanded by an injury resulting from the use of a fork to untie a bootlace; and in nine the eye was lost in consequence of blows inflicted by a fist. The directors gratefully acknowledge various legacies, including one for £1000 from the trustees of the late Professor P. A. Simpson, M.A., M.D., who formerly occupied the chair of Forensic Medicine in the University of Glasgow.

Glasgow Royal Infirmary.

Each week seems to bring some new difficulties or dispute in connexion with the reconstruction scheme. The most recent is a difference of opinion which has manifested itself between the infirmary managers and the Jubilee Memorial Committee on the question of financial responsibility. The managers, as stated in this column last week, wrote accepting the scheme and plan adopted by the committee on the understanding that they were not involved in any financial responsibility. But when this communication was submitted to the Memorial Committee on Feb. 1st it produced an explosion of indignation. Sir David Richmond, in a lengthy speech, moved that the managers' letter be not accepted, and this was passed unanimously. In speaking on the motion Sir David Richmond described the position of the managers as an attempt to absolve themselves of their proper responsibilities and characterised their proposal as an audacious one. The Jubilee Committee had raised £100 000 and now offered to re-build a certain section of the infirmary. When that was performed their function ceased and the managers must rely on their own resources. This view appeared to find general acceptance with the committee, but the public are inclined to ask: If the committee only contemplated a partial action why did they invite a number of architects to submit plans for a complete reconstruction—plans which it would now appear they never had any intention to carry out? The committee have appointed a deputation to confer with the managers with a view to establish a *modus vivendi*, and have determined to issue a statement of their case so as to regain public sympathy. It is not difficult to understand the present confusion and conflict when it is remembered that the promoters of the plan launched their scheme without any consultation with either the managers or professional staff of the infirmary.

Feb. 5th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

A Central Laboratory for the Irish Asylums.

THE Chief Secretary for Ireland on Jan. 29th received a conjoint deputation from the Royal Academy of Medicine in Ireland and the Irish division of the Medico-Psychological Association of Great Britain and Ireland, with reference to the project of establishing a central laboratory, devoted to pathological research in connexion with insanity, for the asylums of Ireland. The object of the deputation was to request the good offices of the Chief Secretary with a view to affording asylum committees the power, which they do not now possess, to contribute to such an institution, the idea of which has met with general approval not only from the medical profession, but from the daily press, both Unionist and Nationalist, and from various influential members of Parliament on both sides of the House. The deputation consisted of Dr. Lombe Atthill (President of the Royal Academy of Medicine in Ireland), Professor D. J. Cunningham, F.R.S., Sir Christopher Nixon, Mr. A. D. O'C. Finegan (secretary of the Irish division of the Medico-Psychological Association), Mr. Conolly Norman, and Dr. W. R. Dawson.

Dr. Atthill, having introduced the deputation, referred to a general statement of its objects, which had already been laid before the Chief Secretary, and said that they were there to afford him any additional information that he might desire.

Sir Christopher Nixon then spoke at some length on the desirability of a central laboratory for the Irish asylums, explaining that it was to be of a similar nature to the laboratories already established by the London County Council for their asylums and by the Scottish asylums at Edinburgh. He thought that it ought to be done thoroughly and that the estimate made by Dr. Dawson of about £600 a year was not enough to allow for its support.

Professor Cunningham pointed out that he understood that the laboratory of the Scottish Asylums was only costing about £600 a year. Ireland was very badly off for laboratories for pathological research as compared with the sister kingdom and he hoped that the Chief Secretary would see his way to assisting in the matter.

The Chief Secretary expressed complete approval of the project of establishing the laboratory. He thought that perhaps the strongest argument in its favour was the existence of similar institutions in England and Scotland. He was of opinion that the proper mode of approaching the subject was not on the merely utilitarian side, but that the scheme was deserving of all encouragement as a means of furthering scientific knowledge by research. There would be the less difficulty in conceding the request of the deputation that no expenditure was asked for, but he feared that it might be objected that the money contributed by the asylums would ultimately have to be supplied from some public source, and he wished to know whether the Irish asylums had any fund at their disposal from which this expenditure might be drawn.

Mr. Norman explained that the public asylums in Ireland had no endowment, but were supported partly by a fixed capitation grant from the Treasury and partly from the rates. The expense, therefore, would fall ultimately on the rates.

The Chief Secretary, resuming, thanked Mr. Norman for his clear statement. He mentioned one or two minor difficulties and said that he could give no actual promise as he did not know when a Bill would be brought in into which the permissive clause desired could be introduced, and that the Government would not think of putting any pressure on the public bodies concerned with the view of compelling them to contribute; but, so far as the permissive clause went, he would be glad if he obtained the approval of his colleagues to insert it into a suitable Bill, and he thought that he might say that this would in all probability be done. He strongly advised, however, that the matter should not be left to the Government merely, but should be urged on the public bodies concerned and brought before the public generally in a way to secure the widest possible support. The £25 or £30 annually which would be required from each county was a very trifling sum.

After a few remarks from Dr. Dawson and Mr. Finegan, Dr. Atthill thanked the Chief Secretary for his reception and the deputation then withdrew.

The Election of a Direct Representative for Ireland on the General Medical Council.

Mr. T. Laffan is contesting the position of Direct Representative for Ireland in the General Medical Council with Sir William Thomson. Mr. Laffan's independence and deep interest in medical education are well known, but if he has no possibility of success his movement will not be for the benefit of the medical profession. The expenditure connected with the Irish Branch Council in the present state of its finances should not be increased, which must be the effect of a contest. There is, too, a decided advantage in avoiding a contest if the result is certain beforehand. It gives additional strength to a candidate unanimously elected. Thus Mr. Laffan incurs great responsibility in his action which only considerable success at the poll will justify.

The Irish Poor-law Medical Service.

A deputation representing the Irish Poor-law Officers' Association waited on the Chief Secretary for Ireland on Jan. 31st and laid before him the necessity of extending to Ireland the English Act which makes it compulsory on local bodies to grant superannuation allowances to all their officials. In reply to Mr. T. W. Russell, M.P., who introduced the deputation, Mr. Wyndham said that if a private Bill was introduced into the House of Commons he would be prepared to support it, although he could not promise that the Government would introduce legislation on the subject. Another deputation representing the Irish Poor-law medical service waited on the Chief Secretary on the following day (Feb. 1st) in reference to the grievance of medical officers as regards superannuation. In reply Mr. Wyndham stated that he was not in favour of drawing a line between the medical and lay officers concerned with the administration in Ireland, but that he would do all that a member of the Government could do to facilitate a private Bill if brought in with something approaching to general consent. A private Bill, he said, which was not contentious, passed through the House of Commons with very little difficulty, as its stages were automatically taken. The accounts of the interviews of these deputations occupied

many columns of the local daily journals, a clear proof that the matter is felt to be one of wide general interest.

A Bacteriological Institute for Ireland.

The annual meeting of the Dublin branch of the British Medical Association was held in Dublin on Jan. 31st, when Sir George F. Duffey was elected President, and delivered an address dealing mainly with the necessity of the establishment of a bacteriological institute for Ireland to be located in Dublin.

Medical Appointment.

Dr. J. B. Story, Professor of Ophthalmic Surgery, Royal College of Surgeons in Ireland, surgeon to the Royal Victoria Eye and Ear Hospital, &c., has been appointed surgeon oculist to His Excellency the Lord Lieutenant of Ireland in the room of the late Dr. A. H. Jacob.

Health of Belfast.

During November 230 cases of zymotic disease were notified—viz., 68 of typhoid fever, 57 of simple continued fever, 40 of erysipelas, 33 of scarlet fever, 20 of diphtheria, nine of membranous croup, and three of puerperal fever. There were 43 deaths from zymotic disease, 95 from phthisis, and 219 from diseases of the respiratory organs. The annual death-rate from all causes was 21·0, that for children under one year old 4·5, and that for those of 60 years and upwards 6·5 per 1000 of the population. In the corresponding period of last year the death-rate from all causes was 26·3, that from zymotic diseases 2·0, and that from chest affections 12·8 per 1000 of the inhabitants. The present death-rate is therefore very low, though slightly greater than that of last month. This is entirely due to causes other than zymotic diseases or chest affections, both of which show a slightly lower rate than in the preceding month. The low rate from the latter cause is due mainly to the unusually high temperature which prevailed during the period, and contrasts very favourably with that of the corresponding month of last year, when it was 12·8.

The Samaritan Hospital, Belfast.

At the annual meeting of the supporters of this hospital held on Feb. 4th it was reported that during the past year 652 patients had been treated in the extern department and 197 in the wards, of whom 157 required surgical treatment. 45 major operations had been performed, and the great majority of the patients had made good recoveries. The hospital was now entirely free of debt, but an additional £100 per annum was still needed from subscribers to make the hospital self-supporting.

Rainfall in Belfast during January.

During the month of January, 1901, the rainfall was 3·05 inches, which fell on 23 days, this amount being well under the average and almost one inch less than the corresponding period of last year.

The Death of the Queen.

Universal sorrow has been felt in Belfast at the passing of the great and good Queen Victoria. On Feb. 2nd all the shops were closed, the city was in a state of mourning, and memorial services were held. In no place in the empire is the feeling of the people more loyal than in Belfast.

Feb. 5th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

An Office Spittoon.

AT the meeting of the Academy of Medicine held on Jan. 15th M. Brouardel read for M. Ch. Périer a note relating to the use of individual spittoons for clerks and office employés as a means of prophylaxis against tuberculosis. M. Périer reminded the meeting that the Academy, on June 28th, 1898, unanimously agreed to the conclusions formulated in a report of Professor Grancher, which was read in the name of the Commission on Tuberculosis. The prophylactic measures recommended as being extremely simple to carry out were as follows:—1. Sputa should be collected in a pocket spittoon holding a little carbolic acid solution of 5 per cent. strength and coloured, or at least a little water. 2. Dust should be avoided as far as possible by the substitution of wiping over furniture, floors, and the like with a damp cloth instead of sweeping or brushing them. 3. All milk, whatever its source, should be boiled before drinking it. These measures are certainly perfectly simple and easy to apply in public life, but in large establishments the problem becomes more and more complex as the number of employés increases and tends to become almost insoluble. Railway companies are a flagrant example of this. The practical difficulties may be resolved into a question of money. Other difficulties may be overcome by persuasion. With regard to passengers all that can be done is to request them not to spit elsewhere than in spittoons, and it would seem easy to demand the same practice from clerks and the like congregated in greater or less numbers in an office where they spend many hours a day. The matter, however, is not so easy. A spittoon used in common is disgusting and a likely source of danger, so that one intended for office clerks must be some form of individual apparatus. Pocket spittoons will not do, for the difficulty of having them administratively cleansed would make them agents of spreading disease rather than a means of defence against it. The apparatus chosen must therefore be one of the class known as "indoor" (*d'appartement*). Professional etiquette does not allow the tuberculous clerks to be ear-marked by having spittoons distributed to them alone, therefore every clerk must have one. The tuberculous clerk does not like everyone to see what he spits up, neither does he want his senses offended by the sight of his colleagues' spittoons. This feeling must be respected; if it is ignored spittoons will be found used as flower vases or hidden away in drawers or cupboards. Thus the desired end is the least attained in the very place where it is most to be desired, and this, too, is due to the resistance to prophylactic measures of the very person whose interest in the success of such measures is the greatest. This resistance, therefore, must be overcome by altering the circumstances which give rise to it. Three conditions must be fulfilled: (1) the spittoon must not be clumsy; (2) it should be concealed in some way; and (3) it must be able to be carried in the hand. The Northern Railway Company is just about to adopt a form of spittoon which seems to fulfil all the above-mentioned conditions. It is made of blue glass and has a handle and it is kept in a box open at one side. On the top of this box, which occupies the usual position of the ink, is placed the inkstand. The clerk, therefore, has only to raise his hand a little higher than usual to dip his pen and this is the sole inconvenience which this little piece of furniture will cause him.

The Influence of Climate upon Experimentally Produced Tuberculosis.

At the Congress upon Tuberculosis held last year at Naples M. Lannelongue, M. Achard, and M. Gaillard communicated the results of their experiments upon the above subjects—results which were astonishing. Their report was read before the Academy of Sciences at the meeting held on Jan. 21st. Two sets of experiments were made. 300 male guinea-pigs were divided into six lots of equal weight and were inoculated simultaneously with an equal dose of human tuberculosis culture. They were then kept in different climates and at different altitudes, such as at sea-level, at a height of 1000 metres above sea-level, in the midst of woods, and in a plain. The two remaining lots of 50 each were kept in a laboratory at Paris where they got no sunshine, or, indeed, much light of any kind. The laboratory was badly ventilated and damp, full of ammoniacal emanations, and an atmosphere containing 1700 microbes to the cubic metre. The temperature was fairly equable, however, and the animals had to keep still because there was no room for them to run about. One experiment lasted for one year, six months, and five days, while the other lasted for one year, two months, and 20 days. Of the laboratory guinea-pigs six remained alive of the first lot and 11 of the second. Of those kept at the sea-level there remained three, of those on the hills four, and of those in the plain one. One important result of these experiments is the fact that tuberculosis behaves very differently in animals of the same class. As in these experiments the doses were equal and the animals of the same class were kept under identical conditions it would seem that the differences in the evolution of the disease were due to the different resistance power of the individual animals. Some died from diffuse tuberculosis at the end of six months and some out of the same lot at the end of 15 or 18 months with only a few very localised thoracic lesions. In three animals the infection either aborted or underwent spontaneous cure.

Radio-pelvigraphy and Radio-pelvimetry at Long Range.

At the meeting of the Academy of Sciences held on

Jan. 21st M. Varnier said that it was possible to obtain, simply by means of a radiograph, a better representation of the bony pelvis than by ordinary pelvimetry. The dimensions were accurate and diameters were obtained of sufficient exactitude to be useful to the obstetrician—namely, those of the false pelvis and of the entrance and exit of the true pelvis. The radiograph was taken in the prone position—i.e., with the subject or patient lying in the ventral position. The bulb is placed at a distance of 2·50 metres from the sensitive plate so that the kathode is perpendicular to an axis passing through the plane of the brim of the pelvis. Under these conditions the exaggerations in the diameters amount only to some five millimetres. The method is applicable in the case of the living woman as well as in the cases of a corpse or of a dry bony pelvis. M. Varnier made some experiments upon both dried specimens and upon dead bodies which showed that if the tube were placed still further off—namely, at a distance of five metres—even the small error of five millimetres was avoided. With an exposure of 10 minutes and a current of 10 ampères at 26 volts M. Varnier obtained a good radiograph of a dried pelvis at a distance of 25 metres. With 20 minutes' exposure a radiograph was obtained at a distance of 30 metres. Two metal bars gave good results at distances of between 35 and 40 metres and a leaden spiral was successfully radiographed at a distance of 45 metres. The dead body could be radiographed at a distance of five metres and the living hand at the same distance in nine minutes. These results give good ground for thinking that before long it will be possible to radiograph with accuracy the pelvis of a living woman at a distance of five metres and thus to avoid the slight exaggeration obtained at a distance of 2 50 metres. Apparently radiography even in its present stage can give superior results in this connexion to those obtained by digital, manual, or instrumental pelvimetry.

Feb. 6th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

On the Relation of the Mucous Membrane of the Nose to the Female Sexual Organs.

SOME years ago Dr. Fliess of Berlin published a monograph on the Relation of the Mucous Membrane of the Nose to the Sexual Organs in Females,[1] and in this work he made the announcement that in the nasal mucous membrane there are two spots which are capable of influencing sensation in the female genital organs. By touching the anterior end of the inferior turbinated bone with a probe a feeling of pain in the hypogastric region is produced in women suffering from dysmenorrhœa, while touching the tuberculum septi produces a pain in the sacral region. The pain produced is always on the side of the body corresponding to the nasal spot that is touched. Dr. Fliess made the further observation that the pain of dysmenorrhœa was immediately relieved when a strong (20 per cent.) solution of cocaine was applied to those two nasal spots, and that dysmenorrhœa could be cured completely by caustic treatment of the anterior part of the inferior turbinated bone and the tuberculum septi. He also asserted that at the time of menstruation a swelling of the mucous membrane of the nose at the two above-mentioned spots could be observed. These statements of Dr. Fliess were much doubted by the medical profession and his mode of treating dysmenorrhœa found no acceptance. Three years ago, however, Dr. A. Schiff of Vienna commenced a re-investigation of the subject at the gynæcological clinic of Professor Chrobak in Vienna. His first series of cases consisted of 26 women suffering from dysmenorrhœa, and the second consisted of 21. Of these 47 cases of dysmenorrhœa with intense continuous pains lasting for some days 37 were treated successfully by the application of cocaine to the turbinated bone and to the tuberculum septi, so that the treatment was successful in 72·4 per cent. of Dr. Schiff's patients. The effect of the application of a 20 per cent. solution of cocaine to the nasal spots lasted each time for nearly 24 hours. The experiments were made in such a way that any influence of suggestion was perfectly excluded. Cocainisation of other parts of the interior of the nose or of the pharynx did not produce any effect on dysmenorrhœal pain. Experiments made by Dr. Schiff also corroborated the statements of Dr. Fliess with regard to the connexion (1) between the tuberculum septi and painful sensations in the sacrum and (2) between the inferior turbinated bone and painful sensations in the abdomen. Dr. Schiff also confirms the observations of Dr. Fliess that dysmenorrhœa caused by mechanical obstruction (stenosis of the uterine orifice, narrow cervical channel, anteflexion of the uterus, &c.) was not influenced by cocainisation of the nasal mucous membrane. Hysterical dysmenorrhœa also did not yield to the cocaine treatment, while even dysmenorrhœa combined with structural disease of the uterus and of the adnexa was curable by the nasal treatment as well as nervous dysmenorrhœa. In 17 cases Dr. Schiff tried the treatment of the "nasal genital spots" (as they are called by Dr. Fliess) with caustics and with electrolysis, which proved perfectly successful in 12 of these patients. Dr. Schiff therefore recommended the nasal treatment of dysmenorrhœa as suggested by Dr. Fliess, and some of the Vienna rhinologists and gynæcologists have reported their experiences at recent meetings of the Vienna Society of Physicians and have spoken in favour of this treatment of dysmenorrhœa. But in the discussion on this subject, which occupied three evenings, no one suggested any satisfactory theory as to this interesting relation between the nose and the female sexual organs. One of the speakers made an allusion to the work of Dr. Head, while another called attention to the old theory of sympathetic action which prevailed in the middle of the nineteenth century (Henle).

Feb. 1st.

[1] THE LANCET, June 26th, 1897, p. 1775.

Medical News.

VACCINATION GRANT.—Dr. W. Napper Nevill, the public vaccinator for Bedminster, has been awarded a grant for successful vaccination from the Local Government Board.

PRESENTATION TO A CENTENARIAN. — Mrs. R. Brembridge of Sidmouth, Devon, celebrated her hundredth birthday on Jan. 21st and was presented with an illuminated address by the tradespeople of the town.

PROFESSOR VIRCHOW'S MUSEUM.—The Vienna *Neue Freie Presse* of Jan. 17th states that a disastrous fire has occurred at the Pathological Institute in Berlin and that the most valuable portion of Professor Virchow's private museum has been destroyed. The loss of the anthropological collection made in the Philippine Islands by Professor Jagor is especially regretted.

AMBULANCE FIRST AID AT COLCHESTER.—At the weekly parade of the Colchester Borough police, held on Feb. 1st, the Mayor of the town presiding, the certificates obtained by the members of the force in connexion with the St. John Ambulance Association, were distributed, after which, on behalf of the class, the Mayor presented Mr. J. E. A. G. Becker, M.B. Edin., L.R.C.P. Lond., M.R.C.S. Eng., for his instructive ambulance lectures, with a gold mounted umbrella, inscribed "Dr. Jonathan Becker, from the Colchester Police Ambulance Class, December, 1900."

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

ADAMS, E. G. B., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed District Medical Officer, Langport Union, vice J. D. Adams, resigned.

ALLEN, F. J., M.D. Cantab., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health by the Westminster Borough Council.

ARKLE, G. M., L.S.A., has been appointed Medical Officer to the Belmont-road Workhouse, West Derby Union, vice J. J. Flinn, resigned.

BAILEY, R. T., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant Medical Officer to the Infirmary, West Derby Union, vice W. R. E. Williams, resigned.

CLAPHAM, CROCHLEY, M.D., F.R.C.P.E., has been appointed Consulting Physician to the Royal Hospital, Sheffield.

DUDFIELD, R., M.B. Camb., L.R.C.P. Lond., M.R.C.S., D.P.H. Camb., has been appointed, *pro tem.*, Medical Officer of Health for the City of London, vice S. Saunders, deceased.

EATON, OLIVER, L.R.C.P. Lond., M.R.C.S., D.P.H. Camb., has been appointed Certifying Surgeon under the Factory Acts for the Exmouth District of Devonshire.

EDMOND, W. R., M.B., C.M. Edin., L R C.P. Edin., M.R.C.S., has been appointed District and Workhouse Medical Officer, Totnes Union, vice L. J. Hains, resigned.

FRASER, JAMES, M.B., C.M. Aberd., has been appointed Deputy Medical Superintendent at the Cleveland-street Asylum, Central London Sick Asylum District.

GREGORY, E. T., M R.C.S., has been appointed District Medical Officer, Paddington.

HEDIN, S. G., M.D. University, Lund, Sweden, has been appointed Chief of the Department of Pathological Chemistry, Jenner Institute of Preventive Medicine, London.

HELM, W. A., M.B., Ch. B. Vict., has been appointed Assistant Medical Officer of the Infirmary, Parish of Birmingham, vice E. C. Gorman, resigned.

HOGG, KATIE WELTON, B A. Sydney, M.B., Ch.B Edin., L.M. Coombe Hospital, Dublin, has been appointed Assistant to the Master, Coombe Hospital, Dublin.

HUNT, J. W., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed First Assistant Medical Officer at the Hendon Asylum, Central London Sick Asylum District.

JENKINS, J. D., M D. Lond., B.S., L.R.C.P., M.R C.S., has been appointed Medical Officer of Health, Rhondda Urban District.

LEATHES, J. B., M.B., B.Ch. Oxon., F.R C.S. Eng., has been appointed Assistant in the Department of Pathological Chemistry, Jenner Institute of Preventive Medicine, London.

LEGG, T. PERCY, M.B., F.R.C.S., has been appointed Assistant Surgeon with charge of Out-Patients to the Royal Free Hospital, Gray's Inn-road, London, W.C.

LITTLEJOHN, E. SYDNEY, B.A., M.D., C.M., has been appointed Visiting Medical Officer to the Thomas Walker Convalescent Hospital, Concord, Sydney, New South Wales.

MARSHALL, T. B., L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer, Maldon Union, vice F. Pershouse, resigned.

NORMAN, R. H., M.D. Lond., B.S., M.R.C.S., L.R.C.P., has been appointed Honorary Physician to the Holloway and North Islington Dispensary.

PRICE, E. O., M.D. Edin., has been appointed Certifying Surgeon under the Factory Acts for the Bangor District of Carnarvonshire.

TROUGHTON, A. J., L.R.C.P., L.R.C.S. Edin., L.F.P. & S. Glasg., has been appointed Medical Officer for the Bentham District of the Settle Union.

WEBSTER, A. J., M.B., C.M. Edin., has been appointed District Medical Officer for the parish of Willesden.

YOUNG, W. J., L.R.C P. Lond., M.R C.S., has been appointed Assistant in the Chemical Department, Jenner Institute of Preventive Medicine, London.

WHYTOCK, A. S., M.A., M.B., Ch.B. Edin., has been appointed Resident House Surgeon to the Brighton and Hove Hospital for Women, vice H. R. L. Joy, resigned.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BATH ROYAL UNITED HOSPITAL.—Resident Medical Officer. Salary £125 per annum, with board, lodging, and washing.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Senior House Surgeon. Salary £65 per annum. Also Junior House Surgeon. Salary £60 per annum, with board, lodgings, and attendance.

BOROUGH HOSPITAL, BIRKENHEAD.—Senior and also Junior Resident House Surgeon. Salary £100 and £80 respectively per annum, with board and washing.

CITY ASYLUM, Birmingham.—Resident Clinical Assistant, single and under 30 years of age. An honorarium attaches to the post of £50 a year, board, lodging, and washing provided.

COUNTY ASYLUM, Whittingham, Lancashire.—Senior Assistant Medical Officer. Salary £225 per annum, rising to £250 at the end of 12 months, with board, lodging, washing, and attendance.

DISTRICT INFIRMARY, Ashton-under-Lyne.—House Surgeon. Salary £100 a year and board and lodging.

DONCASTER GENERAL INFIRMARY AND DISPENSARY.—Assistant House Surgeon, unmarried. Board and residence provided.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark-bridge-road, S.E.—Junior Resident Medical Officer and Registrar. Salary £50, with board and washing.

GLASGOW SAMARITAN HOSPITAL FOR WOMEN. — House Surgeon (female).

GLOUCESTER COUNTY ASYLUM.—Third Assistant Medical Officer. Salary £150 per annum, rising to £180, with board, lodging, and washing.

GUEST HOSPITAL, Dudley.—Senior Resident Medical Officer. Salary £100 per annum, increasing £10 a year to £120, with board, residence, attendance, and washing.

GUILDFORD, GODALMING, AND WOKING JOINT HOSPITAL BOARD.—Medical Officer for the Isolation Hospital at Woodbridge, Guildford. Salary £175 per annum.

GUILDFORD RURAL DISTRICT COUNCIL.—Medical Officer of Health. Salary £250 per annum, which will include travelling and all other expenses.

GUY'S HOSPITAL MEDICAL SCHOOL.—Gordon Lectureship in Experimental Pathology.

HEIGHAM HALL ASYLUM, Norwich.—Assistant Medical Officer.

HULL ROYAL INFIRMARY.—Junior Assistant House Surgeon. Salary £40, with board and lodging.

ISLANDS OF SANDAY AND NORTH RONALDSHAY.—Resident Medical Officer. Salary £80 per annum, with dwelling-house, offices, garden, and ten acres of ground, subject to annual rent of £22.

KENT COUNTY ASYLUM, Barming Heath, Maidstone.—Fourth Assistant Medical Officer and Pathologist. Salary £175 per annum (rising £5 a year), with furnished quarters, attendance, coal, gas, garden produce, and washing.

LINCOLN COUNTY HOSPITAL.—Assistant House Surgeon for six months, eligible for additional six months. Honorarium of £25 for each period of six months, with board, residence, and washing.

LIVERPOOL DISPENSARIES.—Assistant Surgeon, unmarried. Salary £100, with board and apartments.

LONDON COUNTY ASYLUM, Cane-hill, Purley, Surrey.—Junior Assistant Medical Officer, between twenty-three and thirty years of age. Salary £150 per annum, with board, furnished apartments, and washing.

LONDON TEMPERANCE HOSPITAL.—Assistant Surgeon. Honorarium of 50 guineas a year.

METROPOLITAN ASYLUMS BOARD.—Not fewer than Three Assistant Medical Officers (unmarried, and not exceeding 35 years of age), at the Fever and Small-pox Hospitals. Salary £160 per annum during the first year, and (subject to the direction of the Hospital Committee, £180 the second year, and £200 the third and subsequent years, with board, lodging, attendance, and washing (subject to statutory deductions under the Poor-law Officers' Superannuation Act, 1896).

MILLER HOSPITAL AND ROYAL KENT DISPENSARY, Greenwich-road, S.E.—Junior Resident Medical Officer. Salary £60 per annum, with board, attendance, and washing.

NORTH RIDING ASYLUM, Clifton, York.—Assistant Medical Officer, not more than 30 years of age. Salary commencing at £125, rising to £175, and £10 in lieu of liquor, with board, lodging, washing, and attendance.

NOTTINGHAM GENERAL DISPENSARY.—Assistant Resident Surgeon. Salary £140 per annum, all found except board.

NOTTINGHAM GENERAL HOSPITAL.—Assistant House Physician. Salary £100, with board, lodging, and washing. Also Assistant House Surgeon. Salary £100 per annum, with board, lodging, and washing.

OWENS COLLEGE, Manchester.—Senior Demonstrator in Anatomy.

ROYAL EAR HOSPITAL, Soho.—House Surgeon, non-resident. Small honorarium.

ROYAL SEA-BATHING HOSPITAL, Margate.—Assistant Resident Surgeon. Salary £60 per annum, with board and residence.

ST. OLAVE'S UNION.—Assistant to the Medical Officer and Dispenser at the Workhouse, Ladywell, S.E. Salary £50 per annum, with rations, furnished apartments, washing, attendance, and £4 per annum in lieu of beer.

STOCKPORT INFIRMARY.—Junior Assistant House Surgeon for six months. Salary at the rate of £24 per annum, with board, washing, and residence.

THE CHIEF INSPECTOR OF FACTORIES gives notice of vacancies for Certifying Surgeons under the Factory Acts at Sherston, in the County of Wilts; at Linton, in the County of Cambridge; at Wainfleet, in the County of Lincoln; and at Wooler, in the County of Northumberland.

WARNEFORD ASYLUM, Oxford.—Assistant Medical Officer, unmarried. Salary £100 a year, with board, lodging, and washing.

WARRINGTON INFIRMARY AND DISPENSARY.—Senior Resident House Surgeon, unmarried. Salary £120 per annum, with furnished residence and board.

WEST BROMWICH DISTRICT HOSPITAL. — Resident Junior House Surgeon. Salary £50 per annum, with board, lodgings, washing, and attendance.

WOKING URBAN DISTRICT COUNCIL.—Medical Officer of Health. Salary £80 per annum.

YORK COUNTY HOSPITAL.—Resident Assistant House Surgeon. Salary £60 per annum, with board, attendance and washing.

Births, Marriages, and Deaths.

BIRTHS.

BALLINGALL.—On Feb. 2nd, at Grand-parade, St. Leonards-on-Sea, the wife of George A. Ballingall, M.D., of a daughter.

BURTON-FANNING.—On Feb. 4th, at Norwich, the wife of F. W. Burton-Fanning, M.D., of a son.

CROPPER.—On Feb. 5th, at Mount Ballan, Chepstow, the wife of John Cropper, M.B., B.C. Camb., of a daughter.

JOHNSON.—On Feb. 2nd, at Osborne-terrace, Church-street, Egremont, Cheshire, the wife of Alfred Johnson, M.R.C.S., L.R.C.P., of a son.

PATERSON.—On Feb 2nd, at Windsor-place, Cardiff, the wife of Donald Rose Paterson, M.D. Edin., of a daughter.

MARRIAGES.

ARCHER—PHILPOTT.—On the 5th Feb., at Christchurch, Adelaide, South Australia, Edmond Lewis Archer, M.B. Durh., to Helen Philpott of Prince's-square, Bayswater, London. (By cable.)

HAYWARD—ROLLESTON.—On Feb. 4th, at Christ Church, Lancaster-gate, W., John Arthur Hayward, M.D., elder son of the late John Hayward, of Rushall, Wilts, to Rosamund Grace, younger daughter of the late Professor Rolleston, F.R.S., of Oxford.

DEATHS.

BARBER.—On Jan. 24th, at his residence, the Croft, Eastwood, suddenly, Robert David Barber, M.R.C.S. and L.S.A., aged 36 years, youngest son of the late Samuel John Barber, architect, of Eastwood, Notts.

OGILVIE.—On Feb. 2nd, at Welbeck-street, Cavendish-square, Leslie Ogilvie, M.D., M.R.C.P., aged 47 years.

PRICHARD.—On Feb. 2nd, at Redland-road, Bristol, James Edward Prichard, B.A., M.B. Oxon., Surgeon to H.M. Prison, Horfield, Bristol, aged 51 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

PERSONATION AT EXAMINATIONS.

A CASE is at present before the courts in which a medical coach is charged with personating a pupil. Without in any way commenting upon this particular case we may remark that the special system presumably adopted is far superior to that ordinarily used. Supposing that a man is in for an examination and feels doubtful of passing (we will call him A), nothing would seem easier than for A to say to B: "You go into the examination room and do the papers under my name as representing myself." But if any suspicion should arise A is nonplussed. He can only know what went on in the room from hearsay, and he has no means of proving that he was in the room. But supposing A and B to enter jointly for the examination, only entering under each other's names, A will be in a much better position, for if any questions are asked he will have actually been through the examination, although he will probably have failed. A and B may both get through, in which case B simply does nothing more and A takes the position he has rightly won. But if A masquerading as B fails he has only to assume the position which he has fraudulently acquired through the agency of B. The plan is so simple that we almost wonder how many times it has been carried out. The only way in the above hypothetical case in which A could be found guilty would be for the examiners to ask him to write a passage, in which case, as in all probability he could not imitate B's handwriting with exactness, the fraud would come to light. But for the examiners to do this presupposes that they had knowledge of what A was going to do before he did it. The size of modern examination classes renders anything like a personal identification of the candidates very difficult, but something of the kind will have to be done if frauds such as those to which we have alluded are to be made impossible.

SPECIALISM *AD ABSURDUM*.

THE December, 1900, number of the *St. George's Hospital Gazette* contains some amusing verses signed "J. B.," an author who was, if we remember right, responsible for some of the words published in the St. George's Hospital songs, a work reviewed in our columns some two years or so ago. (THE LANCET, Dec. 17th, 1898, p. 1642.) "J. B.'s" lyric is entitled, "Wanted, a Specialist," and sets forth the untimely fate of a titled valetudinarian who was always ill, or thought he was. Eventually he suffered from—but we will let "J. B." tell the story in his own words.

A tumour he developed on
A spot that's quite neglected;
No specialist for just that point
He anywhere detected.

So curiously was it placed,
That, search from toe to crown,
You saw it not when he stood up,
Still less when he sat down.
From day to day the swelling grew,
So vast became that tumour,
You could not say which was the growth
And which Sir Francis Boomer.

And so at last it finished him,
Despite his numerous staff,
And he explained the cause of death
In this his epitaph:

"My ailment could not treated be,
The times were out of joint;
There was no specialist upon
The Perineal point.
Some doctors find their work before,
And others theirs behind.
But none devotes attention to
The spot which I've defined."

We are evidently sadly behind the times. In ancient Egypt, says Herodotus, "every disease hath his several physician," and possibly the end of the new century may see "perinealists."

THE CASE OF MR. JOSEPH HENDERSON MARTIN.

To the Editors of THE LANCET.

SIRS,—I am desired by Mrs. Joseph Henderson Martin to thank on her behalf those who have so generously helped her and her family in the dire straits to which they have been reduced by the sudden breakdown of her husband. The appeal I made to you and which you published in THE LANCET of Nov. 10th last, p. 1395, had produced the sum of £23 and I had begun to think no further subscriptions would be received until this morning's post brought me a very sympathetic note from an old "fellow-student" at present serving in South Africa. He does not wish his name published, but encloses a cheque for £5. The latest report of Mr. Martin is that he is much worse and his death is expected very shortly. If any of your readers could assist, or bring any influence to bear upon those who have the power, to get either of the boys into Epsom or Christ's Hospital it would be most gratefully accepted. Should there be any of those who knew Mr. Martin who failed to notice the previous appeals but who have it in their power to send some pecuniary assistance I would have much pleasure in passing it on to Mrs. Martin. She has been endeavouring to earn some money by taking a house and trying to let it off in furnished apartments. So far she has been unsuccessful, but a little more help now may tide her over the difficult period of waiting until she has formed a connexion. I am, Sirs, yours faithfully,

The Hawthorns, Chester-le-Street, Feb. 4th, 1901. H. LYON SMITH.

VACCINATION GRANTS.

DR. H. HODGSON of Blisworth writes to us to protest against the "advertising by medical men of their having received such an easily acquired thing as a vaccination grant." Dr. Hodgson must surely have forgotten that one of the most effective weapons in the hands of the anti-vaccinationists was the fact that sometimes this trivial operation had been followed by disastrous results owing to a want of due care and circumspection in its performance. The grants are given in recognition of vaccinations properly and carefully performed, and for this reason we have always been glad to record the fact of such grants being awarded, and we shall continue to do so with pleasure.

MEMORIAL TO THE LATE DR. ARCHIBALD HAMILTON JACOB.

THE following contributions to the memorial fund have been received or promised. Cheques and postal orders should be made payable to the honorary treasurers (Sir Charles A. Cameron, C.B., 51, Pembroke-road, Dublin, and Mr. L. H. Ormsby, 92, Merrion-square, Dublin), and crossed "Ulster Bank." The honorary secretary is Mr. George F. Blake, J.P., Registrar of the Royal College of Surgeons in Ireland:—

ACROMEGALY IN THE NEGRO.

IN the *Maryland Medical Journal* for December, 1900, Dr. J. Hall Pleasants of Baltimore describes a case of acromegaly in a negro associated with a low grade of giantism. The individual was apparently a full-blooded negro, probably between 25 and 35 years old, and of a grade of intelligence corresponding to that of an imbecile of the higher type. He weighed 198 lb. and his height was six feet two inches, but his true height must have been at least an inch more than this when allowance was made for his stoop. The thyroid was apparently atrophied, no suggestion of the gland being made out on palpation. The enlargement of the hands was symmetrical in all directions. The left foot, which was slightly the longer of the two, measured 12½ inches in length by 12¾ inches in circumference around the ball of the foot. Radiographs of both hands and feet showed that the enlargement of the bones was most marked in the epiphyses, especially of the terminal phalanges, where there was marked "tufting." Dr. Pleasants has found three cases of acromegaly in the negro already recorded in medical literature.

"CLAIRVOYANCE" AND THE DEATH OF MR. FOXWELL.

ON Feb. 5th Mr. Braxton Hicks held an inquest upon the body of Mr. Percy Lintott Foxwell, which was found in the Thames at Thames Ditton on Jan. 31st. It will be remembered that the deceased left his home on Dec. 20th, 1900, and on the evening of that day a telegram was received by his wife saying that he would not be home to dinner. As next morning he had not returned she informed the police. The widow in her evidence said that on Jan. 5th, as no trace of the missing man had been obtained, she consulted a *clairvoyante*, who by means of crystallomancy told her that her husband had been drowned. She herself looked in the crystal and declared that she saw her husband's form and the

place where it was to be found. "I thought," she is reported as saying, "that it was near some waterworks. ..... I saw waterworks quite plainly and a sort of water tower. The *clairvoyante* said I should have news of my husband in 10 days, but this was wrong." Witness continued that as she got no news she consulted another *clairvoyant*—a man this time who came to her house. He said that her husband had met with foul play and offered to show her where the body lay. They went together to the Mole, which later was dragged. The *clairvoyant* also said that he had seen her husband walking with a woman and a man, that the man felled her husband, and that the two threw the body into the Mole. An open verdict was returned. There will be persons who think that this case proves the value of clairvoyance, but it is obvious that the mystic procedure served only to confuse investigation. Given a man who lives by the river, it is the most probable thing to suggest that after a lengthened disappearance his body should be found there. As for Mrs. Foxwell's evidence we should have been very surprised had she seen anything other than what she did. Her mind was naturally full of her husband and she saw, or thought she saw, his image. The *clairvoyante* had previously mentioned drowning and the daily press had alluded to the same possibility, while the Foxwells lived in a district surrounded by waterworks, so that these edifices naturally came before the mental eye. As for the suggestion of the male seer that some intrigue took place of which Mr. Foxwell was the victim this is a gratuitously cruel assumption.

A FINE FOR DYING.

To the Editors of THE LANCET.

SIRS,—I think the fact mentioned in the inclosed letter which I have received from the relative of a gentleman whom I advised to go to Caux cannot be too widely known. That when English people die abroad their friends should be "fined" in this manner is a great wrong. I have heard of similar cases at Territet and Pau. Some steps ought to be taken to protect our patients from such extortionate practices. I am, Sirs, yours faithfully,

Jan. 22nd, 1901. M.R.C.S., &c.

[INCLOSURE.]

DEAR DR. A.,—Having just returned from Switzerland, where my brother-in-law, Mr. Z., has been staying for the last two months, I think it well to draw your attention to the way I was treated by the officials at the —— Hotel, Caux, S. Montreux. As you are aware, Mr. Z. died at this hotel on the 12th inst., and on my leaving there on the 15th a charge of £40 compensation was made by the hotel. I strongly protested against this, but in the end had to pay, and was informed by the hotel officials that this was a fixed charge made in all cases where a death takes place at this hotel. Yours faithfully,

X. Y. Z.

"AND A BABBLED O' GREEN FIELDS."

THE Rev. D. R. Fotheringham has an interesting article in the February issue of *Knowledge* on Emendation of the Folio Text of Shakespeare, in which he gives the various renderings—good, bad, and otherwise—of the above oft-quoted phrase. He suggests a reading of the passage as follows: "I knew there was but one way (for his nose was as sharp as a pen) and a table of green fields." Emendations of Shakespeare's text have had from time to time to give way to the folio text. In spite of the Rev. D. R. Fotheringham's suggestion that Mrs. Quickly meant that Sir John Falstaff had only one road to go and that the road to the churchyard, ending amid the little mounds scattered over God's green acre, we prefer the more generally accepted rendering.

A QUESTION OF ETIQUETTE.

To the Editors of THE LANCET.

SIRS,—Please can you give me advice in the following case? Dr. A has been the medical attendant to patient C and family. Recently one member of the family has been ill but has called in Dr. B. Neither the patient nor Dr. B has informed Dr. A of this. What ought Dr. A to do in case he is called in to see any member of the family, and also as regards Dr. B? I am, Sirs, yours faithfully,

Feb. 4th, 1901. BEDS.

*** Dr. A can please himself entirely about continuing to attend the C family. A patient has the right to change his medical attendant when and how he likes. His way of doing so may be polite or impolite, but no question save that of courtesy between fellow-citizens can arise. Dr. B transgressed a familiar rule of medical etiquette if the particular member of C's family had previously been A's patient. And if Dr. A refuses further professional relations with him he will be justified, always assuming that Dr. B acted as "Beds" states. Whether he will be wise is for himself to judge, while all signs of ill-feeling between members of the medical profession are regrettable. At any rate, Dr. A will take care that he is completely informed as to the whole episode before he openly resents Dr. B's conduct.—ED. L.

G. P. asks if anyone could kindly inform him where he could hire slides (limelight) and letterpress for a lecture on the Passion Play at Oberammergau? He might apply to Messrs. Newton, Fleet-street, but possibly one of our readers can tell him exactly what he wants to know.

Mizpah.—1. The ingredients differ according to the purpose for which the solution is required. The Local Government Board disinfecting solution for cholera is as follows: Corrosive sublimate, ½ oz.; hydrochloric acid, 1 oz.; soluble aniline blue, 5 grains; water three gallons. This gives a solution of 1 in 1000. 2. For surgical purposes creolin is preferable. The other fluid mentioned should only be used for crude disinfecting purposes.

Qua Hat.—1. There can be no doubt that C's conduct is "covering." The matter should be laid before the General Medical Council. 2. Our correspondent might put the facts before the Local Government Board, but we think it unlikely that he will get a grant for work performed by his predecessor.

Amateur must hold his hand, and we think by his choice of pseudonym that he will be ready to do so. Applied mechanics are often of use in surgery, but it takes more than skill in carpentry to make an operating surgeon.

The Removal of Hæmorrhoids by Excision.—A communication upon this subject, bearing no address, date, or signature, and posted at Manchester, has reached us. We shall be glad to hear from the author.

H. K.—We recommend Gould's Medical Dictionary, published by Messrs. Baillière, Tindall, and Cox, 20 and 21, King William-street, Strand, W.C.

North Warwicks should consult his medical man upon the points which he refers to us. The apparent discrepancy will then probably disappear.

"*Formula No. 4. Directions for Use.*"—We have received a bottle so labeled, but no letter explaining why it was sent to us has reached us.

F.R.C.S.—THE LANCET, Sept. 4th, 1897, p. 609.

Student.—Yes.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (11th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M.).

TUESDAY (12th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

WEDNESDAY (13th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.)

THURSDAY (14th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.) University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

FRIDAY (15th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

SATURDAY (16th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.)

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily

SOCIETIES.

MONDAY (11th).—MEDICAL SOCIETY OF LONDON.—8.30 P.M. Clinical Evening. Dr. C. E. Beevor: Two Cases of Paralysis of the Serratus Magnus and Lower Half of the Trapezius.—Mr. F. C. Wallis: Two Cases of Partial Paralysis of the Fore-arm and Hand (1) from Esmarch's Bandage, (2) from a Splint.—Mr. M. Sheild: (1) Case of Gastro-jejunostomy; (2) Case of Œsophagotomy for "Foreign Body" in a Child aged six years (3) Case of Enormous Chronic Abscess treated by a Novel Method.—Dr. W. Hunter: Case of Pernicious Anæmia after Serum Treatment.—Mr. S. Boyd: Case of Gastro-jejunostomy.—Dr. StClair Thomson: Two Cases to illustrate the desirability of Removing the Tonsils by Enucleation in Certain Instances.—Dr. J. L. Bunch: Case of Abdominal Swelling in a Child aged three years.

SOCIETY OF ARTS.—8 P.M. Mr. W. J. Pope: The Bearings of Geometry on the Chemistry of Fermentation. (Cantor Lecture.)

TUESDAY (12th).—PHARMACEUTICAL SOCIETY OF GREAT BRITAIN (17, Bloomsbury-square W.C.).—8 P.M. Prof. H. G. Greenish: The Percentage Ash of Various Crude Drugs and their Powders. (Communication from the Society's Pharmaceutical Research Laboratory.)

ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—Adjourned Discussion on Cases of Arsenical Beer Poisoning. Dr. Reynolds (Manchester) will show Illustrations and Dr. Dreschfeld, Dr. J. Bury, Dr. Delépine, Dr. D. Mann, Dr. N. Raw, Dr. Kelynack, and Sir Lauder Brunton will speak.

WEDNESDAY (13th).—HUNTERIAN SOCIETY (London Institution, Finsbury-circus).—8 P.M. Annual Meeting. 8.30 P.M. Mr. J. Poland: Hunterian Oration.

SOCIETY OF ARTS.—8 P.M. Mr. W. Thomson: Arsenic in Beer and Food.

THURSDAY (14th).—NEUROLOGICAL SOCIETY OF LONDON (11, Chandos-street, W.).—8.30 P.M. Annual General Meeting. Election of Officers. Dr. W. J. Mickle: Automatic Wandering. (Presidential Address.)

BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover-square, W.).—8 P.M. Specimens will be shown by Mr. F. Edge, Mr. C. Martin, and Dr. H. Macnaughton-Jones. Paper:—Mr. B. Jessett: The Surgical Treatment of Prolapsus Uteri. (President's Introductory Address.)

FRIDAY (15th).—EPIDEMIOLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—8.30 P.M. Paper:—Dr. A. Newsholme (Brighton): The Epidemiological Aspects of Isolation Hospitals.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (Paddington-green Children's Hospital).—5 30 P.M. Cases will be shown by Mr. W. Cheyne, Mr. J. J. Clarke, Mr. A. Lawson, Mr. H. L. Lack, Dr. D. McKenzie, Dr. G. Carpenter, and Dr. L. Guthrie. Paper:—Dr. J. McCaw (Belfast): A Case of Tetanus Neonatorum Successfully Treated with Antitetanic Serum.

SOCIETY OF ANÆSTHETISTS (20, Hanover-square, W.).—8.30 P.M. Paper:—Dr. G. Eastes: The Conclusions of the Anæsthetists' Committee of the British Medical Association.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (11th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. J. F. Payne: Consultation. (Skin.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. Abraham: Skin Affections.

TUESDAY (12th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. W. Ewart: Consultation. (Medical).

WEDNESDAY (13th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. W. H. A. Jacobson: Consultation. (Surgical.)

LONDON THROAT HOSPITAL (204, Gt. Portland street, W.).—5 P.M. Mr. C. Weakes: Examination of the Ear and Nose. (Post-graduate Course.)

NORTH LONDON DISTRICT METROPOLITAN COUNTIES BRANCH BRITISH MEDICAL ASSOCIATION (Royal Free Hospital, Gray's Inn-road, W.C.).—4.15 P.M. District Committee. 4.30 P.M. The Staff of the Hospital will show some interesting Cases. Paper:—Dr. G. A. Heron: Tuberculin Treatment.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Green: Demonstration of Cases in the Wards.

THE SANITARY INSTITUTE, (Parkes Museum, Margaret-street, W.).—8 P.M. Sessional Meeting. Discussion on the State of our Streets (opened by Mr. T. Blashill).

THURSDAY (14th).—CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL (Gray's Inn-road, W.C.).—5 P.M. Dr. D. Grant: Treatment of Malignant and Non-malignant Tumours of the Pharynx and Larynx.

CHARING-CROSS HOSPITAL.—4 P.M. Dr. Abercrombie Medical Cases. (Post graduate Course.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—3 P.M. Dr. H. Low: Class. Roentgen Rays. 4 P.M. Mr. J. Hutchinson: Consultation (Surgical.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. S. Taylor: Physical Diagnosis.

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Mr. Steward: Intussusception.

THE HOSPITAL FOR DISEASES OF THE SKIN (Stamford-street, Blackfriars).—3 P.M. Clinical Demonstration:—Dr. P. S. Abraham.

LONDON TEMPERANCE HOSPITAL.—2 P.M. Dr. S. Fenwick: Clinical and Pathological Demonstration to Senior Students.

ROYAL BRITISH NURSES' ASSOCIATION (10, Orchard-street, Oxford-street, W.).—5 30 P.M. Mrs. H. J. Tennant: Nurses and the Industrial Laws. (Sessional Lecture.)

FRIDAY (15th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. H. Tilley: Consultation. (Throat.)

ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. The Right Rev. Monsignor G. Molloy: Electric Waves.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1900, which was completed with the issue of Dec. 29th, and the Title-page to the Volume were given in THE LANCET of Jan. 5th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1900, bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers, cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France,—J. ASTIER, 8, Rue Traversière, Asnières' Paris.

The Hunterian Oration:

AN ADDRESS ON CRANIOLOGY.

Delivered in the Theatre of the Royal College of Surgeons of England on Feb. 14th, 1901,

BY N. C. MACNAMARA, F.R.C.S. ENG.,

CONSULTING SURGEON TO THE WESTMINSTER HOSPITAL AND TO THE ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.

[MR. MACNAMARA referred to the death of our beloved Queen and to the interest which she had always taken in the efforts made by the medical profession to alleviate human suffering. He then observed that in this time of universal mourning we were consoled by knowing that our King had, by his never-failing courtesy and attention to the numerous demands of his people, already gained their affection. His Majesty had on several occasions evinced his personal interest in the Royal College of Surgeons of England, and it was the sincere hope of that body that he might still find time to help on the beneficent work of the fund which he had established with the object of placing our metropolitan hospitals in a satisfactory financial position. Reference was then made to the loss which the College had sustained since the last oration was delivered in the death of Sir James Paget. Mr. Macnamara proceeded:]

GENTLEMEN,—We have assembled here to-day in order that we may commemorate the merits of John Hunter and such other persons whose labours have contributed to the extension of our knowledge in comparative anatomy, physiology, or surgery. Hunter's life in all its various aspects has been so frequently dwelt on in former orations delivered in this theatre that it is beyond my power to throw any fresh light on this subject. His fame is attributable to his having possessed an intense love of science, indomitable energy, and a self-reliant, manly character. If we turn to his portrait hanging on the walls of this theatre it would seem that at the time when this likeness was painted Hunter was engaged in the study of the craniology of man and anthropoid apes, for on the table before him there is an open volume and on its pages we see clearly drawn a human skull and the skull of a chimpanzee. Hunter is portrayed, pen in hand, in deep thought, having just turned away from the book he had been studying, and though his notes on comparative anatomy were unfortunately destroyed with his other manuscripts we can hardly doubt that craniology was a subject in which he was deeply interested or it would not have held so prominent a position in this famous picture. It would, therefore, seem that on an occasion such as the present we can do no higher honour to Hunter's memory and to that of some of the able men of science who have followed him than by endeavouring to give in as few words as possible a *résumé* of their labours, with especial reference to the subject of craniology and the light it is capable of throwing on the prehistoric inhabitants of western Europe and of the evolution of the race of men to which we belong. One of the most brilliant and original thinkers who has occupied the presidential chair of this College, Sir William Lawrence, in his ever-memorable lectures on the Natural History of Man delivered in this College in the year 1819, from his researches in comparative anatomy, foreshadowed the idea that man and apes were derived from common ancestors. Lawrence's opinions were received with a storm of adverse criticism. Mr. Abernethy, for instance, charged him with "propagating opinions detrimental to society and endeavouring to enforce them for the purpose of loosening those restraints on which the welfare of mankind depend." Time, however, has proved that Lawrence was right, and in the course of lectures delivered in this theatre in February, 1899, Professor Keith, from a careful analysis of the maximum number of anatomical characters common to man and apes, arrived at the conclusion that they are derived from an identical or a kindred stock. While admitting without reserve that man and apes are structurally almost identical, nevertheless, as pointed out by Professor Huxley in the year 1863, they differ very materially as regards the relative weight of their brains. The carcass of a full-grown gorilla is heavier than that of an average-sized European, but it is doubtful whether a healthy adult European's brain ever weighed less than 32 ounces or the brain of the heaviest gorilla ever exceeded 20 ounces in weight.[1] Although at the present time there is this marked relative difference between the weight of the brain and the form of the skulls of Europeans and apes this was not always the case, for the calvaria of the earliest discovered human beings were in form not very far removed from those of contemporary anthropoid apes. This fact leads us to inquire into the nature of the conditions which have led to the increased capacity of the human cranium and to the vast superiority of man's intellectual endowments over those of all the other primates. If we turn to Hunter's preparations in our museum[2] we find among them some remarkable specimens which he describes as "compressed," "unsymmetrical" human crania which he believed were the result of premature consolidation of one or more of the sutures of the skull.[3] Since Hunter's day various authorities have devoted much time to the subject of the abnormal closure of the cranial sutures in man: prominent among them are the names of the chief of England's craniologists, Dr. Thurnam, and Dr. Barnard Davis—the splendid collection of prehistoric and other skulls made by the latter gentleman are now in the possession of our College. From evidence of this nature we have come to learn that the size and form of the skull depends to a large extent on the growth of the bones of which it is formed along the lines of the various cranial sutures.

It is well known that the frontal bone, which forms the vault of the anterior part of the cranium in the young of man and apes, is divided by a suture, and so long as this line of growth, together with the coronal and other sutures by which the frontal is separated from surrounding bones, remains open, the fore part of the skull and with it the anterior fossæ which it encloses can expand. But if the frontal and the other anterior sutures of the cranium consolidate early in life the fore part of the skull cannot increase in capacity beyond the size it had reached in infancy. Professor Deneker[4] in his work on the embryology and development of anthropoid apes has shown that in consequence of the early closure of the anterior sutures of the skull of these animals the fore part of their brain does not increase beyond the size it had attained at the end of the first year of life, but in man these sutures do not consolidate until a much later period, so that the anterior lobes of his brain are enabled to, and actually do, become far more perfectly developed than the corresponding lobes among apes; men of the same bulk have four times as much superficial brain surface as anthropoid apes.[5]

Whatever other functions the anterior lobes of the brain perform, their cortical nerve elements in conjunction with those of the other lobes of the brain control, to a large extent, our higher intellectual faculties. If we study the collection of preparations of the brains of apes in our museum, it seems to me we shall arrive at a similar conclusion to that expressed by Professor Edinger, which is, that the gyri of the brain of man and of the anthropoid apes are similar in character, with the marked exception of those convolutions which enter into the formation of the frontal lobes. The superior and the middle gyri of these lobes in anthropoid apes are always much shorter than they are in

[1] Man's Place in Nature, by Professor T. Huxley, p. 103.
[2] College Catalogue, Nos. 135, 137, and 139.
[3] Professor Virchow who has given much attention to this subject lays down the following law: "In the too early ossification of a suture of the skull the development of the cranium is arrested in the diameter perpendicular to that centre."
[4] Archives de Zoologie Expérimentale et Générale, tome troisième, année 1885.
[5] Among anthropoid apes in consequence of the great size of their frontal sinuses and the roofs of the orbits rising more obliquely into the cranial cavity, the anterior and the inferior walls of the anterior fossæ of their skulls intrude upon and lessen the capacity of this space, and therefore of the anterior lobes of the brain which are contained in these fossæ. Virchow states that "of all parts of the ape's head it is the brain that grows least," even "the largest ape keeps its baby brain." Although we have not sufficient data to fix the absolute duration of the life of anthropoid apes, it is doubtful if they, as a rule, attain the age at which man arrives at his full growth. It is, however, certain that the largest apes are perfectly developed when man is still in his youth, and that the ape's brain has reached perfection before the period of shedding its teeth, while in man it then takes its real first step to perfection. The Cranial Affinities of Man and Apes, by Professor R. Virchow, p. 26. Also Journal of Anatomy and Physiology, New Series, vol. xiii., p. 275.

the brains of average Europeans, and what is of especial importance is, that in the brains of anthropoid apes the inferior frontal gyri only exist in a rudimentary condition of development; this deficiency is very marked with respect to that area of the left inferior gyrus which contains the nerve elements which control our faculty of articulate language. It seems probable that the rudimentary condition of this gyrus in apes is therefore the anatomical expression of the inferiority of these animals to man in intelligence; our intellectual development depending on our possessing the faculty of speech.[6] It may be, anthropoid apes having only rudimentary, if any, specialised nerve centre of speech, that the other parts of their anterior lobes have remained in a comparatively undeveloped condition; whereas the left inferior frontal lobe of man's brain having become highly specialised and with it his power of language, the other convolutions of his anterior lobes, which govern his intellectual faculties, have been stimulated to increased action, and in this way the characteristic expansion of the fore-brain has been evolved among all the more highly civilised races of the human family. But our contention is that the factors which govern the growth of the skull differ from those which develop the brain, and that the imperfect evolution of the frontal lobes among anthropoid apes is to a large extent due to the premature ossification of that part of the skull which encloses the fore-brain. However this may be, the possession of fully-developed anterior lobes of the brain, especially of its left inferior gyrus, is the distinctive character of the central nervous system of all those families of mankind who possess well-developed intellectual capacities. On the other hand, if we compare the skull of an Englishman with that of one of the natives of Australia we see what a wide difference there is between the development of their frontal regions, and also as to the nature of the sutures of many of their skulls.[7] We shall further discover from specimens in our museum that the inhabitants of western Europe in the later tertiary and early quaternary period, as regards the ossification and form, especially of the frontal region of their skulls, more closely resembled that of the chimpanzee than the race of men now inhabiting Europe.[8]

Since Hunter's and Lawrence's time considerable progress has been made in the science of geology and anthropology. Nevertheless, in our search for knowledge concerning the origin and development of pre-historic man in western Europe we are still hampered by the limited supply of his remains It could hardly have been otherwise considering the perishable nature of the human skeleton and the vast length of time, and the great geological changes which have occurred since man appeared in our part of the world. But we have additional evidence concerning the prehistoric inhabitants of this part of Europe, for they have left us some of their imperishable handiwork in the shape of flint and stone implements, which during the past century have been carefully studied in relation to the geological strata in which they were discovered, by Lord Avebury, Professor Boyd Dawkins, Professor Prestwich, Sir John Evans, the late Sir William Flower,[9] together with many other English and foreign anthropologists. From the form and workmanship of these stone implements we are now able to classify, and assign them to the various periods in which they were manufactured by the early inhabitants of our part of the world.

Up to within recent times it was held that no human beings existed on the earth before the quaternary geological epoch, but in the year 1867 the Abbé Burgeois exhibited a collection of chipped flint weapons which he had discovered in a previously undisturbed tertiary formation; it was not, however, until 1872 that these instruments were admitted to have been made by man or some other animal living previously to the commencement of the quaternary period. Precisely similar flint weapons have since been discovered in tertiary strata in various localities in Europe and in Asia. In the year 1894 Dr. Eugene Dubois found the upper part of a skull (calvaria) in close proximity to a femur and two molar teeth in a well-defined tertiary geological formation in the island of Java. Dr. Dubois was employed by the Dutch Government to examine and report on the fossil-bearing strata of Java, and while engaged on this work he discovered imbedded in a hard mass of tertiary tuffs the bones above referred to; he brought these fossils to Europe and submitted them for examination to the leading anatomists of this and other countries. They concurred in the opinion that the femur was a human bone belonging to a man of a very low type; "and demonstrating the fact that while rendering its possessor capable of the bipedal mode of locomotion he still retained some vestiges of adaptation to an arboreal existence."[10] There was a difference of opinion concerning the calvaria, for it was calculated that the capacity of this skull did not exceed 850 cubic centimetres, the capacity of the largest cranium of anthropoid apes being 600 cubic centimetres. Until the Java skull was found the earliest known human skulls had a cranial capacity of about 1220 cubic centimetres. After an exhaustive analysis of the anatomical characters of the Java calvaria as compared with the skulls of man and apes Professor Schwalbe has arrived at the conclusion that the Java skull, taking its capacity and form into consideration, "is on the border-line between that of man and anthropoid apes"; it is more closely allied to the skulls of the Neanderthal group of men than it is to the crania of the higher apes, but it is much nearer in form to the skulls of the chimpanzee than it is to the cranium of the average adult European of the present day. Nevertheless, from a study of the impressions of the convolutions of the brain on the interior of this calvaria it is shown that the inferior frontal convolutions are well marked and approach in form those of man; and although the superficies of this convolution is less than half that of the men of the present day it is double that of the largest brain of any known anthropoid ape.[11] This fact suggests that the Java man possessed in some slight degree the faculty of speech and that his intellectual capacity was higher than that of any of the anthropoid apes. The post-orbital index or narrowing of the Java skull is 19·3, as compared with the average of living Europeans, which is 12. In this measurement the Java skull comes nearer to the Neanderthal group than to that of anthropoid apes.

[6] The Anatomy of the Central Nervous System of Man, Professor Ludwig Edinger, M.D., translated from the fifth German edition by Professor W. S. Hall, 1899, p. 194. Professor D. J. Cunningham states that "one of the most remarkable characters of the cerebrum of the chimpanzee and orang is the total absence of the frontal and orbital opercula," or the pars triangularis which contains Broca's nerve-centre for articulate language. See Contributions to the Surface Anatomy of the Cerebral Hemisphere, by Professor D. J. Cunningham, Dublin, 1892, p. 110.

[7] Professor Huxley held that the organisation of the human brain had more to do with man's intellectual superiority than either its weight or size, and there can be no question that men having small heads are by no means necessarily wanting in mental capacity. But a well-developed frontal region is a characteristic feature of all the more highly civilised communities of the world, and among such people low intellectual endowments or even idiocy is found to be comparatively frequent in those with abnormally small frontal lobes. We agree fully with Professor Huxley that among all the known races of human beings the brain and its including case, the skull, grow together, and the former does not exercise an absolutely predominating influence over the development of the latter. But it is certain that if the anterior part of the skull becomes a shut box early in life it must control the subsequent size and development of the brain which it contains. Professor Welcker, who studied this subject in a thorough Teutonic spirit, arrived at the conclusion that in European races the frontal suture remains open up to the adult period of life in one out of nine persons. Among African races it is not found open at the adult period of life in more than one in 150 persons; and among the aborigines of Australia no adult skull has yet been observed with an open frontal suture. The well-known French anatomist, Gratiolet, states as a result of his researches that "not only the growth of the brain ceases sooner in those races in which the sutures close early, but also that there is a difference between the higher and lower races as to the order in which the sutures are closed normally. In the latter the anterior sutures consolidate before the posterior, and in the higher races it is the reverse, the posterior sutures close earlier than the anterior." M. Gratiolet bases an argument for the greater perfectibility of the higher races upon these facts. On the other hand, Professor L. Edinger is disposed to agree with Professor Peris that not a few men of pre-eminent intellectual power have in early life been affected with slight hydrocephalus which, having abnormally expanded their skulls, has then receded. The brain of such young people has been able to attain a greater capacity than it would have acquired had there been no hydrocephalus to expand the skull-cap. The Anatomy of the Central Nervous System of Man by L. Edinger, M.D.; translated from the fifth German edition by Professor W. S. Hall.

[8] The Origin and Character of the British People, by N. C. Macnamara, p. 25.

[9] Sir William Henry Flower, K.C.B., F.R.S., died on July 1st, 1899; he was for some years the Conservator of the Museum of the Royal College of Surgeons of England, and the Council of the College unanimously passed the following resolution at their meeting on July 13th, 1899: "The Council hereby express their deep regret at the death of Sir William Henry Flower, K.C.B., F.R.S., and their sincere sympathy with Lady Flower and the members of his family. The Council remember how much Sir William Flower, while conservator, did to advance the utility and reputation of the museum by the skilful discharge of his duties and by the eminent position which he won for himself among men of science, and they hereby record their grateful appreciation of his services to the College."

[10] The Journal of Anatomy and Physiology, vol. xxxiii. New series, vol. xiii., p. 273.

[11] The Brain-cast of Pithecanthropus Erectus, by Eug. Dubois, Journal of Anatomy and Physiology, New Series, vol. xiii.

In the employing of skulls, which we believe to be the most reliable test of human races, we classify them under three heads according to the measurements of their cranial indices. In other words, the measurement of the greatest breadth of the cranium, expressed in percentage of its greatest length, is our guide as to the race to which an individual belongs from a craniological point of view. When the cranial index rises above 80 the head is called "brachycephalic," a broad head; when it falls below 75 the term "dolichocephalic" or long head is applied to it. Indices between 75 and 80 are characterised as "mesocephalic," intermediate heads.[12]

We have in our museum casts of two crania, and other bones, forming part of human skeletons which were found resting on a ridge of calcareous rock overlooking the river Orneau in the commune of Spy, Belgium. These remains were unearthed with great care and there is every reason to believe that they were originally deposited where they were discovered, being covered over with four well-defined beds of débris and clay, in which were found the bones of the rhinoceros and the mammoth, also flint weapons of the Mousterian epoch.[13] One of these skulls has marked palæolithic[14] characters, its brow ridges, like those of the higher apes and the Java skull, are prominent and the forehead indicates the low type of human being of which this cranium formed a part. Its form, like that of all the other human inhabitants of Europe as yet discovered in the early geological strata of the quarternary (pre-glacial or inter-glacial) period, is of the long type, its sutures are simple and for the chief part are consolidated. We have another cast, presented to our museum by Professor Huxley, one of our most talented and earnest workers in the science of anthropology, taken from the Neanderthal cranium. This cranium was found with other portions of a human skeleton in a limestone cave near Dusseldorf. This cave was raised some 60 feet above the existing bed of the river Dussel and its floor was covered to a depth of five feet by fluviatile deposits beneath which these human remains were discovered. We have in our collection a skull of the characteristic palæolithic type, presented to the College by one of our former Presidents whose memory is treasured by all who knew him, Professor George Busk; it was found in a layer of brecciated talus under the north front of the Rock of Gibraltar. We have also a cast of the calvaria of one of this race found in county Sligo. Another skull of the same type was discovered at Bury St. Edmunds, with the remains of extinct animals and Mousterian flint weapons.[15]

The anterior surface of the lower jaw among the existing races of Europe projects to form the chin. Among apes the reverse is the case, for the anterior surface of their mandibles recede. The Marlarnaud and the Naulette mandibles, of which we have casts, are evidently those of human beings; they were found in geological formations (which also contained the bones of extinct species of animals and palæolithic flint weapons). These bones are distinctly ape-like in character, having receding anterior surfaces, and also the sockets of all the molars are equal in size. The bones of the legs of these pre-glacial or intra-glacial inhabitants of Europe are of ape-like form, and together with the bones of their arms prove that they were a short powerful race of beings whose average stature did not exceed five feet. They are known as the Neanderthal group of men.

When the glaciers which had extended over the greater part of Europe moved northward the reindeer passed away with them from our part of the continent. These animals, which could easily be captured by man, had roamed in vast herds over the surface of the country and had probably afforded the human inhabitants of that period living in western Europe an ample supply of food. The climate of our part of the world at the termination of the glacial period became such as we now experience. Britain was separated from France by sea, and fine rivers, containing numerous fish, filled the valleys of our land; the red deer, wild horse, and various fleet-footed animals abounded in the splendid forests which overspread the country. But these animals and the fish of our lakes and rivers were not easily captured, and the human inhabitants of western Europe were therefore compelled to exert their intellectual capacities to an extent not heretofore necessary in order to supply themselves with food and with the skins of animals for clothing. Man was able to overcome the difficulties he had to face, possessing an innate power by means of which (as already explained) his brain was able to develop and so meet the increased demand made upon it in the struggle for existence. That such was the case we judge from the discovery in geological formations of the post-glacial period of the skulls of men having the same physical type as those of the strictly palæolithic epoch of western Europe, but with increased brain capacity. These post-glacial human skulls indicate, in my opinion, a gradual transition in form from the ape-like characters of the previous period to a higher standard and distinctly greater brain capacity in the frontal region; this most important question, however, requires further study. With this improvement in the form of the human skull, the flint, stone, bone, and horn instruments made by the post-glacial inhabitants of western Europe become more highly finished, indicating the possession of increasing intellectual power on the part of those who made them.

The Engis skull, of which we have a cast, presented to this College by Sir Charles Lyell, is a well-known example of a human cranium of the early neolithic[16] or post-glacial period. Huxley, in his description of this skull, observes: "It takes us, at least, to the further side of the biological limit which separates the present geological epoch from that which preceded it," that is, from palæolithic times.[17] The Borris and Egisheim skulls probably belong to this period, their characters being similar to those of the Tilbury cranium described by Sir Richard Owen, of which we have casts in our museum. These and various other skulls found in geological formations of the time referred to are all of the same type and lead us to believe that the inhabitants of Europe consisted, in the early neolithic period, of only one race, the descendants of the human beings who inhabited our part of the world during the previous or early palæolithic epoch. They had long (dolichocephalic) skulls, with slightly projecting supra-orbital ridges, well-formed noses, and a fairly-developed frontal region as compared with the far more ancient Java and Neanderthal crania. Their lower jaws and the bones of their legs were less simian in character than those of their remote progenitors; they were a small race of beings. We find no metal weapons or instruments with their remains and we therefore conclude that they were ignorant of the use either of bronze or of iron, nor do they seem to have possessed domestic animals or to have had any knowledge of agriculture. This race of primitive inhabitants of western Europe are best known as the Iberians, and we may conveniently employ this term so long as it is understood to designate the Africo-European stock who were, so far as we know, the only human inhabitants of Europe in the later palæolithic times. It should be clearly understood that no *bonâ-fide* human remains belonging to the early palæolithic period have hitherto been discovered in western Europe which were not of the same type as those above described.

As we pass from the early to the mid-neolithic epoch, we

[12] Assuming the length of the cranium to be 100 the width is expressed as a fraction of it, and is known in the living subject as being the cephalic, and in the bare skull as the cranial index. For instance, if the greatest breadth of a skull is 15·2 centimetres and its length is 19 millimetres we multiply the breadth in this case 15·2 by 100 and divide the product by its length, 19 centimetres, which gives us the cephalic index 80.

[13] The most superficial layer was 9·5 metres thick and was formed by débris which had fallen from the rock above. The second layer was three metres thick and formed of yellow argillaceous tuffs. The third layer was six metres thick, consisting of red clay in which were numerous Mousterian flints and the tusk of a mammoth. The fourth was yellow calcareous clay, immediately beneath which the human remains with bones of extinct animals were found.

[14] The term "palæolithic" is employed to geological formations distinguished by containing the rudest shapes of human stone implements associated with the remains of mammals, some of which are entirely extinct while others have disappeared from the districts where their remains have been found. These deposits may be classed under the heads of alluvium, brick-earth, cavern-beds, calcareous tufas, and loess. Class-book of Geology, Sir A. Geikie, p. 361.

[15] We possess accurate drawings and a description of this cranium. There can be no question that this was a genuine palæolithic skull and demonstrated the presence in the county of Suffolk of this race of human beings when England was still connected by land with France.

[16] The term "neolithic" is used to signify that period in which the stone, bone, and horn implements made by man indicate a considerable advance in the arts of life beyond those discovered in the previous palæolithic epoch. In the neolithic period the remains of the mammoth, rhinoceros, and other prevalent extinct forms of the palæolithic series had almost, if not completely, disappeared from western Europe. The deposits in which neolithic remains are found consist of river gravels, cave floors, peat bogs, raised beaches, &c., &c.

[17] Man's Place in Nature, by Professor Huxley, p. 120. For a description of the Borris skull see S. Laing and Thomas H. Huxley's "Prehistoric Remains of Caithness."

come upon the remains of a race of men who, as regards their physical character and state of civilisation, essentially differ from the people above referred to. The stone implements found with their skeletons are beautifully formed, many of them being highly polished and having sharp cutting edges. A few of the purest bronze axe-heads have been discovered with these remains, and also the bones of domestic animals belonging to species indigenous to Asia but foreign to the palæolithic fauna of Europe. Lastly, we have evidence that these people were acquainted with agriculture and with the manufacture of sun-dried pottery. They paid great respect to their dead chiefs, burying their bodies in natural caves or in tombs formed of huge flagstones placed edgeways side by side with similar stones laid on the upright ones to form the roof of the building. These structures, the well-known long dolmens, have been found, built on precisely the same plan in Ireland, England, the greater part of Europe,[18] the west of Asia, India, Arabia, and northern Africa. They were not only sepulchres for the dead but many of them also contained an altar, a place of mourning, and of offering, where intercession was made to the spirits of departed chiefs by their relations and tribesmen. The Rodmarton long dolmen or temple tomb (near Cirencester) affords us a good example of one of these structures; it is 180 feet in length and 70 feet broad. We have in our museum a fine human skull which was found in this dolmen, with some well-polished stone implements. If we compare the skull with that of palæolithic man or with the skulls of the early neolithic human inhabitants of western Europe we are immediately struck by the marked difference that exists between them and the Rodmarton skull. Dr. Thurman's unique collection of crania may be seen in the Anatomical Museum, Cambridge; these crania for the most part were unearthed by himself from various English long dolmens and barrows, and they resemble in form, although they are of a higher type than, the skulls found in the caves of Cro-Magnon and Mentone; they are identical in character with skulls found in the long dolmens of France and other countries of Europe. The cranial index, capacity, and other features of the bones of these skulls lead us to assign them all to one and the same race, of which the Cro-Magnon are probably some of the very earliest specimens as yet discovered in western Europe. The three Cro-Magnon and three Mentone skeletons were those of people some six feet four inches and upwards in stature, so that a race of giants in far distant times was no myth. Their cranial capacity was above that of average Europeans of the present day. From their physical conformation and from the remains of the animals found buried with them, which are of Asiatic species, and from other evidence, we are led to the conclusion that the Cro-Magnon race represent the advance guard of the proto-Aryan human family, of which the Rodmarton[19] and many other long dolmen skulls show a more advanced type. These people in far distant ages migrated from the east into western Europe and from thence spread into our islands; southwards they passed into India, Persia and Arabia, Asia Minor and northern Africa. Over this vast area and far away in eastern Asia we find their remains with flint and stone implements of the early neolithic type, buried in long dolmens or barrows. The roots of many of the words used by this ancient people exist in most of the languages now spoken in Europe, and their religious sentiments, myths, and above all their racial mental and physical characters, as portrayed in the Rig-Veda and on the ancient monuments of Egypt, are pronounced features in the existing Teutonic and Anglo-Saxon people. From the form of the crania found in many of these long dolmens we know that this tall, fair, handsome, long-skulled race intermarried with the pre-existing short dark Ibèrian inhabitants of Europe. The fair tall race probably did not at any time, unless in the north of Europe, form a large proportion of the population; they were a dominating, fighting, and priestly caste who compelled the primitive small, dark (Iberian) inhabitants of western Europe to work as their slaves.

During the neolithic era, while the descendants of the proto-Aryan stock were slowly feeling their way from the East along the valley of the Danube into Europe, a very different race was passing from Northern Asia into the Baltic provinces. These people formed settlements on the islands of Denmark and westward as far as the north of Ireland. They were the first of the broad-skulled races of the human family who had entered Europe. Their skulls were brachycephalic in form with broad faces and noses, the latter being deeply concave at the base. Their remains are found in the islands of Denmark, especially that of Möen, also in Yorkshire and county Antrim, in which localities their descendants may still be recognised by their physical characters. These people belonged to the stone age of Europe, and by comparing their skulls with those of the Rodmarton or Cro-Magnon crania we see the great difference in form of the prehistoric long and the broad-headed races of men. Until the close of the neolithic epoch there were, therefore, three pure races who formed the sole human inhabitants of Europe, with the exception of those who were the outcome of the intermarriage of the people of these three races with one another.

Passing from the neolithic to the succeeding bronze age we find that Europe, including our islands, was overrun by a small, olive-coloured, broad-skulled people having characteristic Mongolian features. These were the lake-dwellers of Switzerland and other parts of Europe. They were traders in bronze, and probably, as Professor G. Mortillet and other authorities hold, they gradually replaced stone, horn, and bone with bronze instruments and weapons, effecting in this way a great revolution in the social and industrial habits of the pre-existing inhabitants of western Europe. In these far distant times deep mining operations were out of the question. Superficial copper ores were abundant in most parts of Europe and Asia, but alluvial tin was extremely scarce on our continent, and it is still only found in large quantities in south-eastern Asia. Cornwall, the Scilly islands, the south of Ireland, and some few other places also contained superficial ores of tin. It seems probable that the Mongolians inhabiting the highlands of south-eastern Tibet long before the commencement of the bronze age in Europe spread into Burma, the Malay Peninsula, and Cochin China, and there acquired the art of mixing copper and tin in such proportions as to form bronze, the weapons and instruments which they manufactured of this metal being a ready and profitable source of barter in Europe.[20] Together with the broad skulls and other remains of these people we find in the débris of the lake dwellings numerous ornaments made of jade, nephrite, and chloromelanite, minerals found in large quantities in south-eastern Asia but not in Europe; and, lastly, vases on which are depicted people in oriental costume and instruments used only by the south-eastern Tibetans have been discovered in connexion with the remains of the lake-dwellers and the round or oval barrows of Europe. These people, as a rule, cremated the bodies of their dead, and numerous cinerary urns containing their remains are found scattered over the Wiltshire and other ranges of hills in the south of England. Some of their skeletons, however, have been discovered in the round barrows which are so numerous in many parts of England, Ireland, and throughout Europe and Asia. With these remains bronze instruments have been found indicating, like the stone implements of palæolithic man, various stages of excellency in workmanship. One of the finest skulls in our museum was taken from a round barrow at Codford, Wilts. The form of this brachycephalic skull, together with its nasal bones and orbits, are characteristic of the southern Mongolian race, well known to us as the Gurkhas, and Burmese of our Indian empire; a lazy, bright, rollicking, fighting people, intensely superstitious and home-loving—"the Irish of the East" as they have been aptly called. In the course of many centuries the Mongolian people of western Europe have become absorbed into the pre-existing Ibero-Aryan population and a cross-breed has resulted, and from this stock the ancient British people of our islands were derived. Their skulls are mesocephalic (a combination of the long and broad skull) and are amply represented in our museum, the cephalic indices being about 78.[21] Subsequently to the bronze age the ancient Britons were well-nigh exterminated in England by Teutonic races who invaded our country from the north of Europe, the Anglo-Saxons taking the place of the pre-existing ancient British population of England

[18] The construction of these dolmens wherever met with is so similar that we conclude they were the work of one race, or at least of one special confederacy of races.

[19] History of Ancient Wiltshire, by Sir H. C. Hoare, vol. i., Plate XVII., p. 164.

[20] These people without doubt made bronze weapons both in the south of England and of Ireland, for clay moulds have been found there in which weapons of the early bronze period in Europe were cast.

[21] The Mongolian cephalic index is from 80 upwards and that of the Ibero-Aryan is 75 and below that figure.

and Scotland. Nevertheless, in some districts of England such as North Bedfordshire, a number of the descendants of the ancient British stock continue to flourish up to the present day. as also in the greater part of South Wales much of Cornwall, aud the south and west of Ireland, the upper classes in Ireland being clearly derived from the ancient Aryan stock who passed from Gallia into that country during the neolithic period.

We possess the measurements of the heads of some 25,000,000 of the present inhabitants of Europe and the United States of America. From these measurements we learn that a large proportion of the people now dwelling in the countries bordering on the Mediterranean Sea are a short, brunette, long-skulled race, descended, we believe, from those who, from the form of their skulls and other physical characters, occupied that part of Europe and the north of Africa in far distant ages—the Iberian race. Scandinavia and North Germany are inhabited by a tall, fair, long-skulled people derived from the proto-Aryan races who settled in that part of our continent in the neolithic epoch. A vast triangle having its base in eastern Russia and its apex on the Atlantic in south-western France is inhabited by a broad-skulled people derived from Mongoloid or Turanian ancestors. We do not for a moment affirm that these races, as such, have remained pure, far from it, but the results of the measurements of the heads of a great number of the existing inhabitants of Europe point to the conclusions above indicated; and this idea in confirmed by the indices of the splendid collection of crania which occupy so large a space in the museum of this College—a collection which was commenced by John Hunter and upon which a great amount of time and labour has been spent in describing and classifying the skulls which it contains; a work which in my opinion should be completed up to the end of the past century.

The characteristic physical type of palæolithic man may be still recognised among the inhabitants of western Europe, although their skulls have grown more capacious, especially in the frontal region. This change in the form of the cranium marks a corresponding advance in the capacity and organisation of the brain and consequently of the intellectual ability of man: it is in truth evidence of his inherent power to overcome the demand made on his mental capacity in order to cope successfully with his ever-increasing struggle for existence, consequent on the growth in number of his fellow-creatures and the more complicated social conditions of his surroundings. Doubtless the form of skull of a large proportion of the inhabitants of our island indicates a cross-breed formed by the intermarriage of the long and broad-skulled families of man who in distant ages met and intermarried in western Europe, thereby improving the stock of their descendants. Races of men such as the natives of Australia who have remained in an unchanged environment and without intermarriage with other people have made but little progress in their intellectual capacity, the form of their skulls continuing of the same type as those possessed by the palæolithic inhabitants of Europe.

The same causes to which we have referred, acting for long periods of time on people of the same race, has led not only to the hereditary transmission of their physical characters, such as those existing respectively among the northern, central, and southern inhabitants of Europe, but have also developed specialised areas of nerve structure in their brains, by means of which they have come to think, feel, and reason alike. In this way we are able to comprehend the source and the meaning of large bodies of men belonging to the same race being frequently moved to take common action on matters affecting the well-being of their race; they possess, in fact, like innate sentiments although separated from one another by great distances and living under diverse climates and environment. Their emotions and ideals harmonise because their progenitors existed for many ages under similar external conditions and consequently developed like specialised nerve-centres, which have been transmitted together with their physical characters to their successors and become crystallised in their laws and reflected in their conceptions of religion as well as in their social institutions.[22]

In illustration of our meaning we may refer to those revolting pages of history during which Belgium and the Netherlands passed under the dominion of Spain; the Iberian dominating for the time being over a thoroughly Teutonic race. Or we may contrast the existing condition of the Iberian population of South America with the Teutonic Anglo-Saxon inhabitants of the United States or between the latter and the negro population of America.

We have a chart here which shows the result of the recent general election held in this country; the question at issue was one in which the whole of the people in Great Britain were deeply interested. It is remarkable what a large proportion of the inhabitants of England and of Scotland, mainly of Anglo-Saxon origin, voted together on this subject; whereas a contrary opinion regarding this same question was held by the greater proportion of the people of Ireland, and to a large extent by the Welsh, most of whom are derived from Ibero-Mongolian ancestors. It is difficult to account for the diversity in the sentiments of the people above referred to unless we consider it due to their racial mental qualities.[23] Environment has doubtless played an important part in the evolution of these people, but their inherited racial character has had more to do with the position which the Anglo-Saxon race has gained in the world than the mineral wealth, climate, or protection afforded us by our seagirt coast.

The environment under which even a few generations of men exist would seem capable of influencing the structure of their central nervous system, as illustrated by comparing the mental qualities of our rural and urban population. The conditions under which the city-bred person, child and man, lives engender in the course of a few generations an unstable state of nerve structure, resulting in an excitable character, which if carried beyond a certain point leads to unsoundness of mind and may account for the increasing number of lunatics in this and the other large cities of Europe. General Sir Redvers Buller again, in speaking of the soldiers under his command in South Africa, refers to the fact that our city-born men have imperfect sight compared with men reared in the open plains of the Transvaal, thus affording us another example of the effects of environment on the race.[24] These are a few of the many interesting and important subjects which arise in connexion with the study of anthropology, including craniology; and the contents of our museum and library offer unrivalled opportunities to the student seeking for knowledge in those branches of science.

In conclusion, as already stated, much of Hunter's reputation was founded on the result of his labours in those branches of science which tend to elucidate man's nature; and during the past century a succession of English surgeons have carried on the work commenced by our great master, enriching our museum and endeavouring to make this College, not only an examining and licensing body, but, what it certainly should be, an Imperial Institution for the cultivation and diffusion of those departments of knowledge which bear on the art and science of surgery. The ideas entertained by John Hunter's immediate successors on this subject were ably stated by Sir William Lawrence in his lectures already referred to. He observes that "our own individual credit, and the dignity, honour, and reputation of our body, which we are bound to maintain, demand that surgeons should not be behind any other class in the possession either of the cultivation of branches of knowledge directly connected with surgery or in any of the collateral pursuits less immediately attached to it. It is only in reference to such views and objects that the Hunterian collection could have been accepted or can be of any use to this College." Hunter would, if he had still been with us, have thrown all his indomitable energies into the successful working of such an institution, and amidst the turmoil, strife, and competition going on around him would,

[22] The Origin and Character of the British People, by N. C. Macnamara, p. 192. See also the Westminster Review, December, 1900, p. 634.

[23] This idea is confirmed by the result of the elections that have lately taken place in Canada and the United States of America. The younger branch of our Anglo-Saxon race, forming as they do by far the larger proportion of the inhabitants of these vast and flourishing dominions, had to solve a similar question to that placed before the people of Great Britain, and they have responded by a vast majority to this call on precisely the same lines as those followed by Englishmen, moved, we believe, by common racial inherent sentiments.

[24] Sir Redvers Buller in one of his speeches is reported to have stated that: "In the first instance many of our men are city born, and England is not a very large country. We went out to a region where the principal number of our enemies were born in a very open country, a very large country, and it is not untrue to say that practically the vision, the ordinary sight, of our enemy was two miles at least further than the average sight of the English who were fighting against them. That is a matter of actual fact. An ordinary Dutchman or African can see a man coming towards him two miles before the man approaching can detect him."

as we see him in this picture, have been engaged in the earnest, accurate, patient study of nature. It remains for our younger members to emulate the example set them by John Hunter and by such service to secure for themselves lasting satisfaction, and beyond that add to the real dignity and utility of their College and their profession.

Three Lectures
ON
THE SURGERY OF PREGNANCY AND LABOUR COMPLICATED WITH TUMOURS.

Delivered at the Medical Graduates' College and Polyclinic on Jan. 11th, 18th, and 25th, 1901,

BY J. BLAND-SUTTON, F.R.C.S. ENG.,
SURGEON TO THE CHELSEA HOSPITAL FOR WOMEN; ASSISTANT SURGEON TO THE MIDDLESEX HOSPITAL.

LECTURE II.[1]

Delivered on Jan. 18th.

WHEN PREGNANCY AND FIBROIDS CO-EXIST.

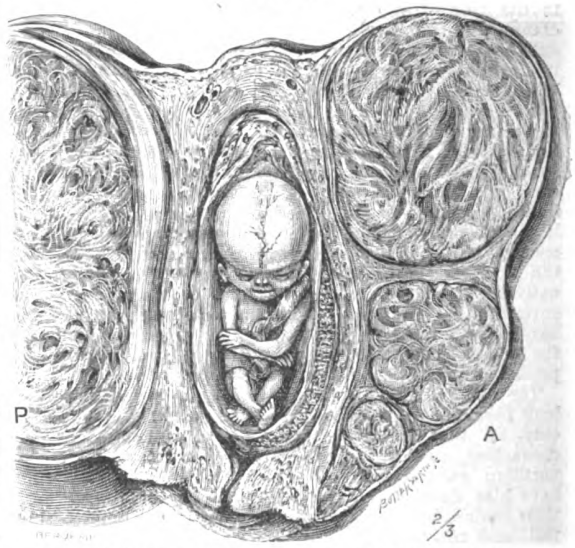
GENTLEMEN,—My object in this lecture is to set forth the perils which beset a woman when with her uterus occupied by fibroids she is so unfortunate as to conceive. This is a matter which has not received adequate consideration from the standpoint of modern surgery, and although many cases of this unlucky combination have been recorded no serious attempt has been made to deal with it in a comprehensive manner and in the light of the recent extraordinary advances in the surgery of the uterus. It will be useful to indicate the danger attending pregnancy, travail, and the puerperium complicated by uterine fibroids by some actual records.

CASE 1.—In 1897 I saw in consultation a woman, 40 years of age, who had been married 14 years. Ten days before I saw her the patient had been delivered of a child at term. Coincidently with the expulsion of the placenta an oval body, in shape like a fœtal head, presented at the mouth of the womb; this was at first regarded as the head of a twin and efforts were made to draw it forth, but careful examination revealed some nodular outgrowths on the uterus and no further attempts were made to extract this mass. When I saw the patient there was no difficulty as to the nature of the condition because a large submucous and septic fibroid protruded from the uterus into the vagina. The woman died three days later, being the thirteenth day after delivery. No operation could be entertained, the patient being too ill.

The practitioners in this instance were not the first to be puzzled by a large submucous fibroid in process of extrusion in a parturient woman. Yeld recorded a case[2] in which a woman, the mother of nine children, was delivered of a hydrocephalic child which had been dead for three days. A sessile tumour mistaken for the placenta was removed with the help of a blunt hook and three medical men. The woman died from shock two hours later. The tumour was nine inches in circumference and weighed four and a half pounds. Yeld ends his account of this dreadful case with the observation that "one similar to which has not, I believe, been recorded in the annals of midwifery practice." Even practitioners well experienced in midwifery, theoretical as well as practical, are occasionally puzzled by these complicated pregnancies, and a case recorded by such a well-qualified observer as Dr. F. H. Champneys may be used to illustrate this point. In 1877 he was called by the resident midwifery assistant at St. Bartholomew's Hospital to a woman, 25 years of age. The assistant, Dr. Maberley, recognised the case to be one of labour complicated with a fibroid and he determined to dilate the mouth of the womb and attempt delivery, but this being impracticable and thinking that craniotomy or perhaps Cæsarean section might be required he sent for Dr. Champneys who was acting for the physician accoucheurs. Dr. Champneys could not at first satisfy himself whether he had to deal with an extra- as well as an intra-uterine twin, an ovarian tumour, or a fibroid. He succeeded in pushing the tumour out of the pelvis and as it could then be felt above the pubes he punctured it through the hypogastrium with a trocar; as no fluid issued Dr. Champneys decided that it was a fibroid. Chloroform being administered a still-born child was, after some difficulty and "the expenditure of unusual force," extracted. This happened on Jan. 10th. A few days later the tumour was septic and sloughing and the patient continued so ill that she was conveyed into St. Bartholomew's Hospital. On Feb. 19th, exactly five weeks after her terrible delivery, a sloughing fibroid escaped from the uterus. She now began to improve and left the hospital eight weeks after delivery. This case is recorded in the St. Bartholomew's Hospital Reports, 1877. Dr. Champneys also took pains to collect from the current literature of that period quite a large number of records which show that fibroids often complicate labour *and frequently cause death.*

A comprehensive study of the cases in which fibroids complicate pregnancy indicates quite clearly that the life of the woman is in jeopardy not only so long as the fœtus remains within the uterus but also when it is expelled, whether this occurs prematurely or at the full time. The dangers may be set down in the following order. 1. The presence of the tumour not only leads to impaction but tends to produce abortion. In this event the mother sometimes dies from hæmorrhage. 2. A submucous fibroid may become septic and slough. More rarely a submucous fibroid may be driven out before the presenting part; more frequently it is extruded about five or six weeks subsequently to the delivery of the child. 3. A submucous fibroid may become œdematous and when the uterus empties itself the tumour may inflame and lead to peritonitis or the formation of extremely vascular adhesions. 4. Occasionally a pedunculated subserous fibroid possesses such a long pedicle that it will become incarcerated in the pelvis and simulate an ovarian tumour. This condition is fortunately rare. It will be an advantage to illustrate some of these conditions by the details of actual cases. An early (if not the earliest) sign to lead a pregnant woman with a fibroid in the uterus to seek relief is pain. This is in the majority of cases due to impaction.

FIG. 3.



A gravid uterus, with fibroids, in sagittal section. At the beginning of the third month impaction occurred; this was relieved, and as the uterus with its tumours was too long to lie in its natural position axial rotation occurred. The antero-posterior length of the distorted organ was 20 centimetres. Only a portion of the large tumour is shown in the figure. A, Anterior aspect of the uterus. P, Posterior aspect of the uterus.

CASE 2.—A woman, 30 years of age, married in October, 1897, and after missing three menstrual periods was seized with severe pain in the pelvis and retention of urine. Dr. Mills found a mass in the pelvis which he regarded as a

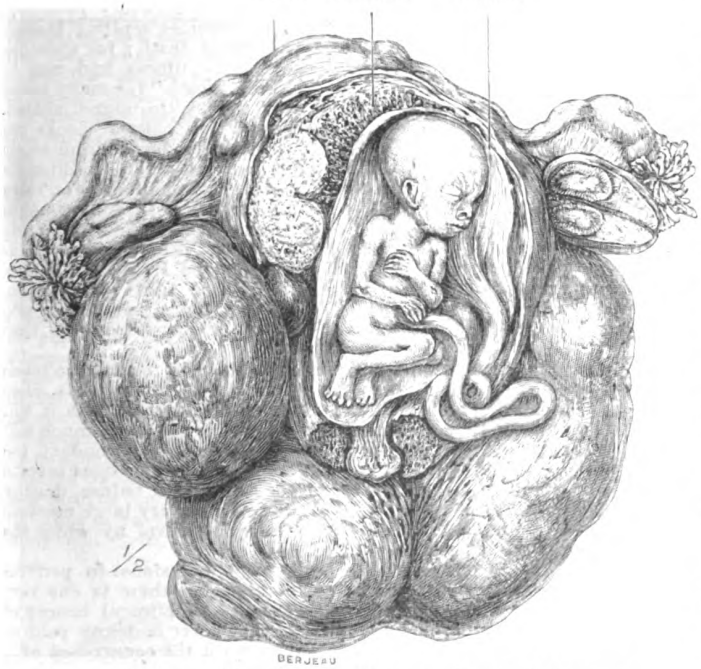
[1] Lecture I. was published in THE LANCET of Feb. 9th, p. 382.
[2] Brit. Med. Jour., 1871, vol. i., p. 586.

retroverted gravid uterus. With the aid of an anæsthetic he succeeded in pushing the mass out of the pelvis but found that a "swelling" had appeared in each iliac fossa. These "swellings" were very tender and the patient complained of great pain. It was clear that either a fibroid of the uterus or an ovarian tumour was complicating pregnancy. Prompt measures were taken and next morning I performed cœliotomy and found a fibroid growing from the posterior wall of the uterus lying in the right iliac fossa, and a smaller tumour in the anterior wall occupied the left iliac fossa. I removed the uterus and the left ovary and Fallopian tube. The patient recovered and was in excellent health in 1900.

A study of the uterus after its removal is very instructive. It will be seen on reference to Fig. 3 (which was drawn from the parts after they had been carefully hardened and bisected) that the total antero-posterior length of the uterus

FIG. 4.

Tube. Placenta. Amnion.



A pregnant uterus, with multiple fibroids, removed from a single woman, aged 31 years. The operation was undertaken because the tumour had undergone rapid enlargement. The patient absolutely denied the probability of pregnancy. (Museum of St. Mary's Hospital.)

is 20 centimetres. The average conjugate diameter of a pelvis with the soft parts in position is about 10 centimetres, so that it was quite impossible for this uterus to be accommodated in its normal position in the pelvis. It appeared to me that the fibroid on the posterior wall of the uterus became gradually impacted in the pelvis as the uterus enlarged after conception, and at last induced retention of urine by compressing the urethra. When Dr. H. H. Mills relieved the impaction axial rotation took place to the extent of a quarter of a circle, due to the accommodation of the fibroids in the iliac fossæ, hence the pain and acute suffering which supervened after the uterus was pushed out of the true pelvis.

The study of this case induced me to look very carefully into the clinical records of cases where trouble arose early in the course of pregnancy associated with uterine fibroids, and there is one fact which stands out in a very significant manner—in quite a large number of instances the patient seeks relief because her tumour has increased rapidly and causes pain, but she rarely suspects that she is pregnant. It is important to remember this even in cases where women have lived in sterile wedlock many years. The following case will serve as an example.

CASE 3.—A woman, 44 years of age, had been married 14 years and had never been pregnant. On examination an abdominal tumour was found which caused great pain and as it seemed to be quickly increasing in size the patient sought admission into the Middlesex Hospital. Mr. Andrew Clark performed hysterectomy as the uterus was occupied by two large submucous fibroids. The uterus also contained a fœtus of about four and a half months. The patient made an excellent recovery.[3]

The museum of St. Mary's Hospital contains a specimen which illustrates in an unmistakeable way the futility of relying on the statements of unmarried women when pregnancy is concerned. The preparation (Fig. 4) is a uterus deformed by fibroids and occupied by a fœtus of about the fourth month of gestation removed from a single woman, 31 years of age; the operation was undertaken because the "tumour" had undergone rapid enlargement and the patient absolutely denied the probability of pregnancy.

In each of these cases the fact of the uterus being gravid was overlooked. The line of treatment adopted probably saved each patient a serious illness.

The impaction of a uterus with fibroids secondary to conception is not only responsible for pain, and in a certain proportion of cases to retention of urine from direct pressure on the urethra, but it probably accounts for the frequency with which abortion occurs under these conditions, and it is interesting to observe how even a relatively small fibroid will impede the ascension of the uterus as it enlarges during pregnancy and give rise to great trouble. For example, a woman under my own care four months advanced in pregnancy complained of pain due to a "lump" in the left iliac fossa. This lump elicited a variety of opinions at a consultation held to determine the course of treatment. I regarded it as a sessile fibroid of the uterus near the brim of the pelvis. At the operation this was found to be the case. The tumour in shape was something like a kidney and about as big, and had grown from the anterior wall of the uterus near the left cornu; as the uterus increased this fibroid became impacted under the pelvic brim. The uterus continued to rise out of the pelvis as the pregnancy progressed, but the fibroid remained fixed, and as a result the uterus slowly rotated, and at the time of the operation the degree of rotation amounted to rather more than a quarter of a circle. I enucleated the tumour. The patient recovered, the pregnancy went to term, and she was successfully delivered of a living child.

CASE 4.—In December, 1900, a woman, 32 years of age, was placed under my care with the following story. She had been married four years and had twice miscarried, and was now pregnant for the third time; the pregnancy had advanced to the fourth month when she began to experience great pain in the pelvis, but being particularly anxious to possess a living child, Mr. L. E. S. Beer had kept her in bed for a month. As the uterus rose in the abdomen a tumour became obvious, but we could not determine its precise character. As it was clearly the source of her pain I explored it through an oblique incision to the right of the linea alba and found a subserous fibro-myoma growing from the uterus and adherent to the bladder. The tumour was of about the size of a tennis ball and I succeeded in peeling the bladder from it without opening its cavity. The patient made an uninterrupted recovery, the pregnancy continues undisturbed, and I am full of hope that the gestation will end in success.

I have subjoined some cases in the form of a table, because I think few surgeons really appreciate the way in which the uterus tolerates surgical operations even when pregnant. In Dr. W. H. Fenton's case I was present at the operation, which was undertaken with the impression that the tumour was of ovarian origin and had probably undergone axial rotation. The fibro-myoma in that case was larger than a cricket-ball. An important clinical point and one that requires emphasising is this: in all the cases

[3] Middlesex Hospital Reports, 1897, p. 218.

in the table the patients complained of great and continuous pain, and it was for the relief of pain that the operations were undertaken. In nearly all the

cases the operation was undertaken on an erroneous diagnosis. In my first case the swelling was thought to be a pyosalpinx. Knowsley Thornton considered the tumour in his case to be an ovarian cyst, and Morris diagnosed the swelling in his patient to be of renal origin.

I have often recognised pedunculated and sessile fibroids in a pregnant uterus that caused no inconvenience, but when a fibroid interferes with the bladder or the bowel it will cause pain, and should it become incarcerated in the recess of the sacrum or under the brim of the pelvis and prevent the uterus rising into the abdomen it will also cause pain, but, what is more significant, it will provoke abortion.

Fibroids when they complicate pregnancy are not only dangerous in that they frequently cause abortion but may obstruct delivery when the pregnancy goes to full time; the duration of pregnancy may be absolutely normal and the child may be born without any hindrance, but the fibroid itself is inimical to the life of the mother.

One of the great dangers which surround all women during their lying-in is septic endometritis, and this is a serious sequel to delivery with a normal uterus, but it is a more serious matter when an infected uterus contains fibroids. This is a subject to which I have given close attention and it is worth our careful consideration. Every fibroid is completely invested by a covering of fibrous tissue which not only isolates it from the tissues of the uterus but also supplies it with blood, for the vessels on which the fibroid depends for its nourishment and growth are derived from those ramifying in the capsule. When this capsule is damaged the fibroid invariably dies, and if septic organisms gain access to it gangrene is the inevitable result. This is always a dangerous condition and in many instances entails the death of the individual.

Necrosis and subsequent gangrene of a fibroid arise usually from injury, and this may be due to the examination of the uterus with a sound, dilators, curette, or the forceps of the accoucheur. Occasionally it happens as a result of the efforts of the uterus itself to expel a pedunculated fibroid. It will serve our purpose to study a case of this kind in detail, as it will enable us to appreciate more readily what happens when a fibroid is injured in the course of a labour.

CASE 5.—Some years ago I saw a woman with a large black mass protruding from the vagina; blood oozed freely from it and she was extremely weak and ill, with a temperature of 103° F. and a pulse-rate of 120 to the minute. This mass was a pedunculated fibroid which had been extruded from the uterus and had become septic; its capsule had been destroyed and the whole tumour was in reality a stinking slough. Under chloroform it was removed and the uterine cavity was thoroughly irrigated with sublimate solution (1 in 2000). For a few days all seemed well, there was no pain or tenderness; on the evening of the third day after the removal of the slough the patient complained of sudden abdominal pain followed by the signs of shock; this gradually passed off and severe peritonitis followed and she died two days later. At the post-mortem examination the uterine cavity was found to be occupied by sloughs of endometrium and the mucous membrane of the Fallopian tube had also sloughed; fragments of it were projecting through the unclosed cœlomic ostia of the tubes and septic fluid had also leaked in the general peritoneal cavity and set up fatal peritonitis. This instructive specimen is preserved in the museum of the Royal College of Surgeons of England. It formed one of the series of specimens which accompanied my essay for which that College awarded me the Jacksonian Prize in 1892. This specimen illustrates extremely well the pathological changes which arise in fibroids subsequently to abortion or delivery. The expulsive efforts of the uterus force out the fœtus and in a fair proportion of cases they will cause the fibroid to extrude into the vagina, where it becomes septic and initiates a condition of things such as existed in the case just described. When the tumour is small and sessile the nature of the case is not always suspected until profuse bleeding from the uterus, and the occurrence of urgent clinical signs of sepsis lead to a physical examination of the uterus.

It does not necessarily follow that in every parturient woman with a fibroid the tumour becomes septic. Indeed, a septic fibroid does not always cause death; for example, Dr. Champneys's patient had a grave illness and may be described as being in the "jaws of death" for many weeks until the sloughs escaped and the septic signs abated. There is a wonderful means by which nature blocks one avenue by which lethal effects are produced from septic processes arising in the uterine cavity. When the infective process extends from the endometrium to the Fallopian tubes it often leads to occlusion of the cœlomic ostium of the tube and thus prevents the direct leakage of septic matter into the peritoneal recesses of the pelvis. This happens more frequently than many of us suspect and I have on several occasions drawn attention to the fact that septic endometritis after labour is responsible for a far larger proportion of cases of acute and chronic salpingitis than gonorrhœa.

I am anxious not to be misunderstood in relation to sepsis and fibroids. It does not by any means follow that when a parturient woman has a fibroid in her uterus that it will of necessity become septic during her puerperium, much will depend on the care and skill of the medical attendant, the midwife, and the nurse; and even if the tumour does become septic and slough it need not, as I have said before, destroy the patient, the ultimate effect will in a very large measure depend upon the variety of the micro-organism by which the patient has become infected.

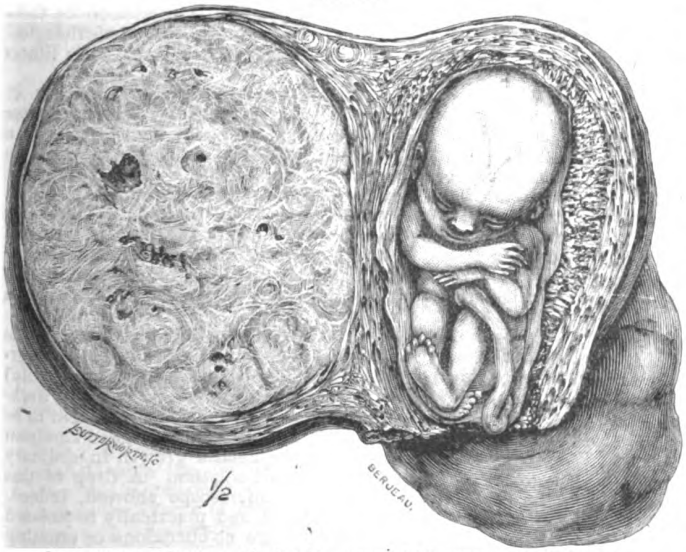
It has happened to me on many occasions to perform hysterectomy on account of fibroids, and there is one very important feature which comes out in the clinical history of the patients: many state that they never had any pain or suspected the existence of a tumour till the occurrence of a miscarriage; since then good health has been denied them. When one gets a definite statement of this kind it generally happens at the operation that one or both Fallopian tubes have the cœlomic ostium occluded and the tube distended with sterile serum and sometimes with pus. These distended tubes are the legacy of a septic endometritis supervening on the abortion. On one occasion I had an excellent opportunity of studying the early stage of septic infection in a fibroid.

CASE 6.—A woman, 35 years of age, had conceived and, as far as she could reckon, the pregnancy had advanced about three and a half months when such disturbance ensued as led the medical man in charge to fear the existence of tubal rather than uterine pregnancy. We could not decide whether the pregnancy was uterine or tubal, but we also determined that it was complicated with a tumour; the same evening abortion occurred. Dr. Champneys also saw the patient with us, but could not decide whether the tumour was ovarian or a fibroid, and we decided to leave the tumour until after the puerperium unless dangerous symptoms supervened. A few days later the abdominal signs were ominous, and on the ninth day of the puerperium I performed cœliotomy and removed a pedunculated subserous fibroid as big as a cocoa-nut. This fibroid adhered to the adjacent bowel, the omentum, and the peritoneum, it was very soft and œdematous, and the abdomen contained a quantity of yellow glutinous lymph. Microscopic examination showed the tumour to be thoroughly infiltrated with inflammatory cells. The patient made an uneventful recovery and 30 months afterwards became the mother of a fine infant.

The condition of the tumour in this case furnished me with some interesting points. It has happened to me whilst operating on subserous fibroids, and also in watching operations by other surgeons, to find the tumour adherent to the great omentum and this structure had the epiploic arteries and veins enormously developed, the arteries being in many instances as big as the radials; thus the whole of the omentum connected with the tumour resembled an enormous rete composed of large tortuous arteries, veins, and occasionally lymphatics as big as the cephalic vein; the dilated lymphatics contained fluid of a pale straw colour. The contrast of the maroon tint of the blood in the arteries, the deep blue of the veins, and the light yellow of the lymphatics with their very thin walls, formed an anatomical picture scarcely likely to be forgotten by those who have had to deal with such a condition. The interest in relation to our present study is this: all the cases in which I have met with this great development of the blood-vessels in the omentum have occurred in patients who have been pregnant, and they have always furnished the definite statement that the tumour began to trouble them after a confinement or miscarriage, and that they had a long illness. This I would interpret in the following way. Labour or abortion was complicated with a fibroid. The endometrium became infected and this extended to the fibroid and led to the formation of adhesions and their gradual vascularisation from the omental vessels; eventually free anastomosis arose between the vessels in the capsule of the fibroid and the epiploic arteries. The most extraordinary example of a pathological arterial rete of this kind I have ever seen was in a case of tubal pregnancy which went to term and the placental vessels directly anastomosed with the enlarged vessels in the great omentum.

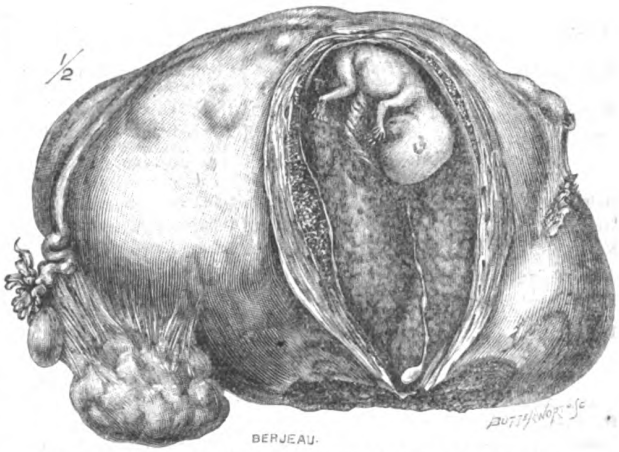
The facts at our disposal indicate very certainly that uterine fibroids, even more than ovarian cysts, are a grave menace to successful pregnancy and in a large number of cases are directly responsible for a premature termination of the pregnancy, and when abortion happens the patient requires to be safeguarded most strictly against infection, for it may involve the fibroid, and in this event the patient not only runs a very great risk of losing her life, but she certainly will have a long illness, and in many instances a serious operation may be necessary to prevent her from becoming a chronic invalid. We must not forget that a woman may have one and indeed several fibroids in her uterus and yet be the happy and healthy mother of children, but no one will deny that the presence of a fibroid in a gravid uterus is an additional peril to those which are proverbially associated with pregnancy. It occasionally happens that a woman comes under observation known to be suffering from a combination of pregnancy and fibroids and a careful examination discloses the fact that if the pregnancy goes to term delivery by the natural passages would be impossible. In these circumstances hysterectomy is justifiable. This is illustrated by a specimen in the museum of St. Bartholomew's Hospital (Fig. 5). It is a gravid uterus with a large fibroid in its wall removed by cœliotomy from a woman, 44 years of age, under the care of Dr. W. S. A. Griffith. He found that the fibroid so blocked the pelvis that delivery would be impossible. It was removed by Mr. Harrison Cripps.

FIG. 5.



A pregnant uterus, with fibroids, removed by supra-vaginal hysterectomy from a woman, aged 44 years. The fœtus is about four and a half months. (Museum of St. Bartholomew's Hospital.)

FIG. 6.



A pregnant uterus, with fibroids, removed from a woman who five years previously had nearly lost her life from the obstruction the fibroids offered to the passage of the fœtus. Case 4 in Table II.

CASE 7.—A married woman came under my care in great distress because she knew that she had fibroids and feared that conception had also occurred. Her distress was due to the fact that five years previously she had been in the same straits and though prematurely confined had been so ill and ran such a narrow risk of dying that she wished to avoid such a contingency if possible. At a consultation it was decided that one of the fibroids so blocked the pelvis that if the pregnancy continued the fœtus could not be born through the natural passage; after very careful consideration hysterectomy was advised and successfully carried through (Fig. 6).

We may now turn our attention to cases where, in spite of the fibroid, pregnancy has continued uninterruptedly to term and where labour is imminent or actually in progress when the accoucheur finds the way barred by a tumour which he regards as a fibroid. A study of the literature indicates that in Great Britain the principles which used to guide the conduct of such labours were as follows. Attempts should be made to push the tumour out of the pelvis and then extract the fœtus by version or with the aid of forceps. If the tumour cannot be pushed out of the pelvis then Cæsarean section should be performed. In recent years, however, when the impaction cannot be relieved it has become the practice with many obstetric surgeons to perform Cæsarean section and then to remove the uterus, a method which has been eminently successful. It is also a practical fact well worth bearing in mind that when the uterine tissues are softened by the pregnancy and the ligaments are stretched by the growing uterus hysterectomy is a simpler operation and the convalescence is usually quicker than when performed for fibroids alone. In order to show that this improved method of dealing with fibroids complicating pregnancy and labour is finding favour I have added a list of some recently recorded operations which have been

performed in London with the hope that other operators may be induced to record their experience.

It cannot to my mind be too strongly set forth that in cases where a fibroid has obstructed labour and has been successfully "pushed up," as the phrase goes, if any dangerous symptoms supervene during the puerperium then cœliotomy, followed by myomectomy (or hysterectomy if the need be), should be carried out without delay. That myomectomy and enucleation are successful during the puerperium I have already testified in this lecture (Table I.).

I am well aware that in a very large number of instances fibroids and pregnancy coexist and no harm ensues, for though the tumour occupies the pelvis in the early stages it is so much "part and parcel" of the uterus that, as the enlarging organ rises out of the pelvis, it carries the fibroids with it. In the case of an incarcerated ovarian tumour it is different, for the more the fundus of the uterus ascends the more the ovarian pedicle elongates and the more perfect the incarceration becomes.

From a very broad survey of this question I have arrived at the following deduction: ovarian tumours have given more trouble to pregnant and parturient women than fibroids, but fibroids have been far more lethal as they so frequently destroy puerperal women from sepsis. The whole subject is an instructive study of the baleful effects which environment often imposes on so-called innocent tumours.

REMARKS ON AGGLUTINATION BY PLAGUE BLOOD.

BY E. KLEIN, M.D., F.R.S.

VARIOUS observers have stated that the blood of persons convalescent from plague possesses the power of agglutinating plague bacilli of culture. To mention a few only of these observers, the late Dr. Leumann in several reports of the Bombay Plague Laboratory found that the blood not only of persons convalescent from an attack of plague, but also of those who had been injected with the Haffkine plague prophylactic, possesses marked agglutinating action; Zabolotny,[1] as also other observers, speaks of a similar agglutinating power of the blood of plague convalescents; and Dr. A. K. Chalmers, at the meeting of the Incorporated Society of Medical Officers of Health on Nov. 10th, 1900, mentioned that in Glasgow this agglutinating action of the blood of plague convalescents was also ascertained.

Now, without in the slightest degree intending to cast any doubt whatever on the correctness of these observations and statements, it may be permissible to point out that unless the method according to which the experiments were made is mentioned in detail the nature of these observations is not easy of comprehension. All those who have worked on specific agglutinations and all those who are constantly using this most valuable diagnostic method—to wit, in typhoid fever—are agreed on this, that all agglutination experiments must start with a good emulsion of the microbes on which the agglutinating action of blood has to be tested. Unless a good emulsion is used in which the bacilli are isolated and evenly distributed no conclusion can be drawn; indeed, no reliable experiment at all can be started. If, for instance, a distribution of the bacilli is employed in which already at starting the bacilli are aggregated in larger and smaller clumps, the experiment of testing the agglutinating action of blood, serum, or any other fluid on such an emulsion can be of little value. It is well known that of the typhoid bacilli, cholera vibrios, and other microbes a good emulsion—i.e., a uniform distribution of the microbes either as a broth culture, or as a bouillon, or salt emulsion made from the growth on agar or gelatin—can easily be prepared, and therefore no difficulty is experienced or apprehended in starting without further precautions the required agglutination experiments. But this, unfortunately, is not the case with the plague bacilli. The plague bacilli in a broth culture form naturally at the sides and the bottom of the broth granular and floccular aggregations—masses of chains of bacilli intimately bound together—the main part of the broth remaining clear. However much such a broth culture is shaken there are always present, when a droplet is examined under the microscope, a sufficient number of clumps to vitiate all further proceeding in the agglutination test. On agar, glycerine-agar, or serum the plague bacilli form a characteristic sticky viscid growth, due to the fact that the bacilli produce on these media a gelatinous, sticky, interstitial substance, by which the bacilli remain coherent. If a particle of such a growth is placed in bouillon no amount of shaking can produce a workable emulsion, microscopic specimens show numerous clumps and coherent masses, and therefore no reliable test can be made with such a distribution. This will be sufficient to show that to perform the agglutination test with plague blood on plague culture the initial desideratum of having a good emulsion of plague bacilli meets with great difficulties. These were the difficulties I met with in trying to repeat the observations recorded by the above-named authors, for, unfortunately, the method of preparing the required emulsion was not stated by them. A positive agglutination test of plague bacillus might not only be of theoretical value, but, as must be obvious, would possess great practical importance in those cases of convalescent persons in whom the bacteriological or other evidence did not directly demonstrate their illness to have been plague.

It was known to me that gelatin surface cultures of plague bacilli do not possess the viscidity and stickiness characteristic of agar or serum cultures; they appear of a drier character, and therefore I tried to obtain a workable emulsion from such a gelatin culture. Consequently a particle of the growth was distributed in bouillon and by shaking this it was attempted to produce a workable emulsion. But this was of no avail; the bacilli, although in many places in an isolated condition or in small masses, remained sufficiently numerous in bigger clumps, and therefore made this distribution unfit and unsatisfactory for a reliable experiment.

It occurred to me, however, that by distributing the gelatin growth in physiological salt solution—a fluid otherwise known to be capable of dissolving interstitial (globulin) substances, it might be possible to obtain a good and workable emulsion. The experiment proved this contention to be correct. There was no difficulty in making a good emulsion by shaking up a particle of the gelatin growth in ordinary (0·75 per cent.) physiological salt solution. A drop of this emulsion examined under the microscope showed, indeed, the bacilli uniformly distributed and practically in isolated condition; at any rate, there were no obnoxious or vitiating clumps. And such a microscopic specimen shows (sealed up) even after being kept for 24 hours, the same isolated condition of the bacilli. The first and important difficulty of having a good emulsion of plague bacilli was thus overcome. It was now possible to proceed to test on such an emulsion the agglutinating action of plague blood or of any other substance.

I had already from a number of previous indications the

[1] Archives des Sciences Biologiques de St. Pétersbourg, vol. viii., N. 1, referred to in the Centralblatt für Bakteriologie und Parasitenk., Band xxviii., N. 25, p. 881.

suspicion that bouillon *per se* is not without effect in causing agglutination of plague bacilli, and the first experiments were therefore made with sterile alkaline bouillon. The result was sufficiently striking. If to a good salt emulsion of plague bacilli (taken from the gelatin surface) bouillon is added in the proportion of 1 of bouillon to 20 of emulsion the result of positive agglutination is evident already in from 12 to 15 minutes. Instead of the uniform distribution of more or less single bacilli there is now everywhere a general massing of the bacilli into larger and smaller clumps and a corresponding disappearance of the previous single bacilli. Even when the dilution is 1 in 40 the same clumping is noticeable, though somewhat later (in from 15 to 30 minutes). From this it is evident that for the performance of the agglutination experiment with plague bacilli the method of making an emulsion of the microbe in bouillon generally used for other bacilli—e.g., typhoid and cholera—is not applicable.

The next experiments were made with normal human blood and with normal mouse's blood. In all instances a good salt emulsion of plague bacilli from a gelatin culture was made and to this the blood was added in the proportion of 1 in 20 and 1 in 40. Not even after 24 hours was there any difference noticeable between the control (emulsion) specimen and the specimen made with emulsion *plus* blood.

The next experiments were made with blood of rats which had been injected first with Haffkine's prophylactic, then with small doses and finally with large doses of living plague culture. These latter injections produced slight bubo and general illness, but after a few days the animals recovered, whereas the control (normal) rats injected at the same time and with the same amount of the same living culture succumbed. The blood of two such rats which had recovered was used for the agglutination test, three and five weeks respectively after the last injection. The proportion of blood added to the salt emulsion of plague bacilli was 1 in 20 and 1 in 40 and the result was distinct agglutination in 10 minutes; by the end of 15 minutes or so all bacilli had clumped into smaller and larger clumps, leaving the intervening parts practically free of isolated bacilli Such rats' blood produced not only sooner the agglutination but the clumps were larger than in the case of the bouillon experiment. From this, I think, it follows that the blood of the rat, convalescent from plague, has positive agglutinating action on an emulsion of plague bacilli. Whether tested by this method also the blood of a human being convalescent from a mild attack of plague or after infection with Haffkine prophylactic has, as might be expected, this agglutinating action, I am from my own experience unable to say.

St. Bartholomew's Hospital.

WHY ARE BOTH LEGS OF THE SAME LENGTH?

BY GEORGE E. WHERRY, M.C.CANTAB., F.R.C.S.ENG.

THE poet Pope must have been easily satisfied when he wrote the lines—

> "Why has not man a microscopic eye?
> For this plain reason—man is not a fly."

Here we are reminded of the tailor who thought that man had two legs in order that he might wear breeches. In this new century we are more persistent in our inquiries, less satisfied with our answers, and some of us even wish to interfere or try to mend. For these body-cobblers all simple mechanical influences become of the utmost importance as being to some extent under their control. Man cannot meddle with the mechanism of the sun, and we have therefore the more confidence in daylight; nevertheless we may watch the effects of great laws, as of symmetry or heredity, and help ourselves by the study.

The general question whether "a *man* by taking thought can add one cubit to his stature" is not now much to be considered, but rather whether a *child* has chances of gaining length of limbs apart from inherited potentiality. Though much would depend on heredity, something would depend on conditions during growth. The Eton boy is taller than the workhouse boy of the same age; and Frederick William's tall guardsmen with selected tall wives may still stamp the present generation with a tall progeny. Grogan found a long-legged people living on the Nile sudd who may have developed from mudlarks to storks by the unusual conditions of their life for generations, and I am prepared to believe that individuals and peoples may be stunted in stature by weight-carrying and over-walking in youth.

As a fact, our lower limbs are not usually both of the same length, though they are so for all practical purposes. There are slight differences in length, usually an excess in the left, which does not influence the gait or in any way limit the usefulness of the legs in progression. That the lower limbs are longer than the upper is an advantage; but it is interesting to note that they are not born so, and the short helpless lower limbs of the infant are rather prehensile than ambulatory. With regard to the upper limbs of the adult these prehensile organs are shorter and smaller than the lower limbs, and the right arm is almost always longer than the left. The right humerus and radius taken together will be from one-third to three-fourths of an inch longer than the left. This is not so at birth, but becomes so during growth, and the increased development is probably associated with the use of the right arm and hand. In the gorilla and anthropoid apes, the adult skeletons which I have measured in the Cambridge museum show no such difference. It interests me to note that the right arm of man gains on the left not only in size and strength but also in length by excessive use. The gorilla, having no need to use one limb more than the other, is ambidextrous or ambisinistrous. A climbing monkey has been seen to swing from bar to bar across a space of 20 feet and in the transit to catch a bird in the air with wonderful precision, assisting itself with five prehensile organs—four limbs and a tail.

The length of the arms in the anthropoid apes is very striking and one would like to train a baby gorilla to stand and walk upon its legs expecting that it would grow longer in the legs than other gorillas. It may be if a child were trained to walk upon its hands, and the feet were used like those of the Brussels painter with prehensile toes, the arms might then grow as long and as strong as the legs. About legginess generally it may be stated that we are not born leggy like the foal or the kangaroo, but we gradually achieve legginess. At about 15 years of age the human boy shows what he can do in that direction and develops this strikingly human characteristic. What an extraordinary difference in this aspect from the foal, who has to follow the mare about the field, and is born with limbs well adapted for that purpose.

The kangaroo is an example of an animal with disproportionately long hind limbs. In the development of this creature after an intra-uterine life of less than six weeks the mother by means of its mouth then takes from the womb the tiny one-inch fœtus and places it inside the pouch, where the fœtus finds, and hangs on to, the teat of the mother's mammary gland; by the time the baby kangaroo leaves this second uterus, in about nine months, its hind limbs have acquired their adult proportions and become serviceable for hopping about. After this the infant kangaroo occasionally returns for food and shelter to the marsupial pouch always to its own teat though younger infants are in possession of other teats.

In organs which grow continuously through life it is necessary for healthy development that natural resistances should be continually offered to the growing organ. Without this opposition the individual suffers, as in the case of the rat when, a tooth being lost, the unopposed tooth tacks the jaws together or seriously hampers the bite by its increased length.

With regard to mechanical causes which influence growth it is difficult to avoid the speculation that the direction of a spiral often depends upon some outside resistance so applied as to determine a right or left helix, even if the spiral itself be not so made. That this direction is so determined is made probable by considering a carpenter's shaving. The reason of the spiral form of a right-handed screw which is usually seen in shavings is because the workman tends to drive his plane slightly to the left. He plays, as a cricketer would say "a little to the on"; if he made a perfect stroke fore and aft a simple coil would result; in "playing to the off" or standing on the wrong side of the bench he would make a left-handed twist in his shaving. The carpenter is usually all unconscious of the twist that he makes and

imparts to the shavings and it is a pretty piece of evidence of how slight and subtle force determines the direction of a spiral.[1]

In the rare specimen in the Cambridge museum of a narwhal with two tusks both the tusks have a sinistral spiral. In the usual one-tusked specimen the left is always developed and also carries throughout a sinistral twist, but the unerupted tusk, 10 inches long, which is buried in the bone, exhibits a perfectly straight fibre and no spiral is to be found. This suggests that the spiral is formed and its direction determined after it leaves the bone and becomes opposed to the waves during growth. The creature ploughs or planes (as does the carpenter) and plays to one side so as to give a sinistral direction to the spiral which develops in growth. When by rare chance a double tusk appears the creature still from habit carries its head to one side and both tusks show the sinistral spiral. The spiral horns of animals such as the koodoo are symmetrically arranged, are right and left by certain rules to which few exceptions[2] only are found. These horns keep approximately of the same length, partly by being exposed to equal resistances and like conditions during growth. The hoofs of a sheep which had lived among the boggy soil of the Falklands show the necessity of suitable resistances as well as the effect of undue moisture. Each portion of the cloven hoof is of enormous size and length, twisted and intertwined in a complicated twirl.

To return to the question of the length of the lower limbs, it is important to consider the fact that bones increase in length not so much by interstitial deposit as by addition to their ends; that is, by progressive ossification of the layer of cartilage which intervenes between the end of the shaft and the epiphysis Ossification goes on till the component parts of the bone are all united by bony matter, and thus the stature of the individual is determined. If from inflammation or injury an epiphysis be damaged one limb may be shorter than the other, or inflammatory stimulation may even induce an increased length in the bone affected. The skeletons of tortoises, not being subjected to sudden jars, have no epiphyses at the ends of the long bones. Whereas in the leaping frog the extremities of the humerus and femur long remain as separate epiphyses.

The continuous concussions to which the ends of the bones of the lower limbs are exposed, when a vigorous child is excited by its own natural spirit to run about, are doubtless of great value in assisting the growth in length of the lower limbs, which soon lose their infantile character, and become adapted for running and walking. By exposing the lower limbs to the same influences and resistances during their entire growth we manage to maintain them of the same size and of the same length, and gentle jars upon the epiphyses at the joints may be considered favourable to growth.

If, then, by any evil chance one limb be shorter than the other in a growing child, we must find the cause of that shortening, and if there be nothing against the rational plan of treatment—after study of the epiphyses and joints of the child—it will not suffice merely to put a boot with a thicker sole on the shorter limb so as to avoid a tilted pelvis and a crooked spine. In such a case carefully planned exercises will be needed, especially directed to the shorter limb, during all the period of growth. The punishment must be made to fit the crime, and, so soon as the limb can be trained to a sufficient standard of strength, one-legged balancing and hopping exercises will encourage the growth of the weak limb.

It is probable that sometimes when the heel can be brought down in the short leg that there is more shock to the limb on that side during progression until the boot be worn, and if intermittent pressures and succussions are of any value in respect of gaining length this boot may actually retard growth by lessening the shocks, unless suitable exercises be performed with the short limb. No doubt the short limb will require all care to give it rests as well as resistances but the hopping (as at hop-scotch) or one-legged exercises (like the one-legged knee-bender) gradually taken will give a power of poise or balance which is of great advantage.

A child may have quite a strong limb and yet a poor balance, defining balance as the power of maintaining the equipoise under all conditions with the minimum of muscular effort. Continual standing about and long walks are bad for growth and are to be avoided; cycling should only be used to save fatigue in going to or from the playing-field or gymnasium. Long-continued cycling is bad and resembles walking on air-cushions which would give no judicious stimulation of the joints. Much cycling for a female child would run some risk of narrowing the pelvis, yet the cycle could be wisely used on the way to the dancing class or school. The natural gait of the child is a hop, skip, and jump, and not the walk two by two of the old-fashioned girls' school.

The difference between the bone-setter and the surgeon is nowhere more apparent than in cases demanding exactly opposite plans of treatment. In cases of disordered joints and epiphyses rest is imperatively demanded, whether in bed or on Thomas's splints, whereas with sound joints and epiphyses the limb must be actively used under supervision of the surgeon. In such a common case as that of a child with one lower limb shorter than the other after an attack of infantile paralysis the nerve-storm has been long past, and it is necessary to remove the effects of the storm on the limb. After tenotomy, passive movements, and massage have been considered or used, then the child with a suitable boot should begin and continue the one-legged exercises which have been chosen as most helpful, and these must be watched and worked hopefully during the time of growth. The exercises chosen must include those which give gentle natural shocks to the joints. The effect on the local circulation of stamping and beating the feet is valuable, and is immediately felt when an Alpine guide beats the half frozen feet of his Herr.

In the foregoing remarks it will be easy to separate the facts from mere speculations. The practical suggestions are founded, I hope, on the facts, and they are set forth in the belief that, with all the care taken to fix and set at rest the joints and limbs, it is easy to neglect stimulation and encouragement of growth when active treatment is needed. The period of growth in the human subject is so prolonged that a surgeon past middle age may not hope to live to see the results of his advice.

Cambridge.

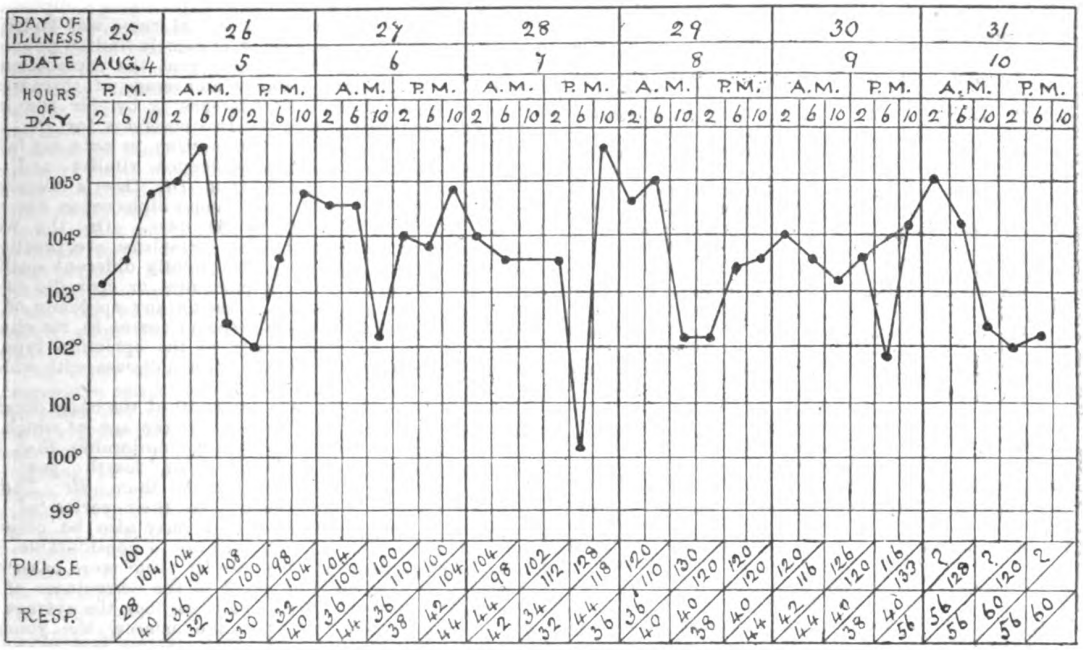
A CASE OF SUBACUTE GLANDERS.

By JOHN FAWCETT, M.D., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO GUY'S HOSPITAL;
AND
WALTER C. C. PAKES, M.R.C.S. ENG., L.R.C.P. LOND., D.P.H. CANTAB.,
BACTERIOLOGIST TO GUY'S HOSPITAL.

A MAN, aged 45 years, a cab proprietor, was admitted into Guy's Hospital on August 4th, 1900, under the care of one of us. Three weeks before he was taken ill a horse in his stables, supposed to have been suffering from glanders, had been killed. The patient first felt ill on July 9th, and between this time and the date of admission he had a small abscess on the left forearm, which was opened, and elsewhere on the body several other swellings which did not suppurate. During this period the patient was so ill that he had to remain in bed, his temperature being raised throughout, and on several occasions reaching 104° F.

On admission the patient, a big stout man, was obviously very ill. He was very tremulous, but breathing comfortably. His temperature was 103·2°, his pulse was 100, and his respirations were from 30 to 40 per minute. On the left forearm was a shallow sinus which led into the above-mentioned abscess cavity and from which exuded a little thin discharge. Over the back of the right elbow there was some cellulitis and also over the back of the first and second right metacarpal bones. A similar swelling was present on the inner side of the left knee. These swellings somewhat resembled patches of erythema nodosum No fluctuation was detected in them nor any œdema of the surrounding tissue. A few mucous râles were heard over the bases of the lungs posteriorly. No physical signs were present on examination of any other of the organs. The urine did not contain albumin. There was no glandular enlargement and rhinorrhœa was not present. There was a small furuncle on the buttock, from which a cultivation was made. For the first three days after admission the condition of the patient did not materially alter, but on August 7th he

became distinctly worse and had recurrent attacks of difficulty in breathing, saying "he was sure he would be choked." On the 8th a crop of small papules, which became pustular appeared on the back. On the 9th there were a few fresh papules on the right thigh. The left knee-joint was found to contain some fluid. During this day and the next the attacks of difficulty in breathing became more marked and the patient, becoming gradually worse, died on the 10th. The course of the temperature and pulse is shown on the accompanying chart. Cultivations were made from the furuncles, but up to the time of death no positive result had been obtained.



Necropsy.—The lungs were œdematous, but there were no nodules or any pneumonic areas to be seen. All the other viscera appeared normal to the naked eye and no foci of inflammation or suppuration were present anywhere in, or among, the viscera. The left knee-joint contained a thin, yellowish, glairy fluid and over the right elbow the tissues were infiltrated with a similar oily fluid. Cultivations were made from the heart blood, the spleen, and from the fluid in the region of the elbow and from the left knee-joint.

Remarks.—The case was one of subacute glanders of a month's duration. During life, although the history and some of the signs and symptoms suggested the possibility of glanders, yet the clinical evidence, in the absence of bacteriological proof, was not sufficiently clear to allow of a positive diagnosis of glanders being arrived at. Although the patient was very ill the local manifestations of the disease were slight and might have been those of a subacute pyæmia of other origin. They were (1) subcutaneous swellings. (2) a few small furuncles, (3) a small abscess in the left forearm, and (4) the presence of fluid in the left knee-joint. There were no typical ulcers of the skin, no well-marked bullous or pustular eruptions, no rhinorrhœa, and no intra-muscular abscesses, the presence of any of which would have helped to distingush the case with more certainty as one of glanders.

Bacteriology.—The small furuncle upon the buttock was examined microscopically and culturally. Bacilli were seen in the pus which resembled the bacillus mallei, but the cultures were full of staphylococci and no bacillus mallei was found upon them. The heart blood, the spleen, and the fluid from the knee-joint were examined and mixed cultures containing a glanders-like bacillus were obtained. These were plated and pure cultures of the bacillus were obtained. The bacillus had all the typical morphological appearances and gave the staining and cultural reactions of the bacillus mallei. A small quantity of a glycerine-agar culture was inoculated into the peritoneum of a male guinea-pig and after 48 hours its testicles were distinctly enlarged and inflamed. It was killed after four days and pus containing bacillus mallei was found inside the tunica vaginalis and small abscesses in the body of the testicle which on section were seen to contain characteristic bacilli. There can be no doubt, therefore, that the case was one of glanders. It was suspected before death that the bacilli which had been found were really glanders bacilli, but owing to the contamination with other bacteria it was not proved. There would appear to be little doubt that had the abscess upon the forearm been examined bacteriologically the bacillus mallei would have been found. There seems also to be little doubt that had it not been for the bacteriological examination the case would not have been certainly diagnosed as one of glanders.

POSTERIOR BASIC MENINGITIS.

BY HUGH THURSFIELD, M.D. OXON., M.R.C.P. LOND.,
MEDICAL REGISTRAR AND PATHOLOGIST TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, W.C.

THE disease which is known in this country by the name of "posterior basic meningitis" has always attracted much attention at the Hospital for Sick Children, where the names of Dr. S. J. Gee, Sir Thomas Barlow, Dr. D. B. Lees, and more recently of Dr. Still, are always associated with it. The last-named, while holding the post of registrar and pathologist, described a diplococcus which he had found constantly present in the meningeal exudations—a diplococcus which in most respects resembles the diplococcus intracellularis of Weichselbaum, the chief differences being the greater vitality of the organism found by Still and the fact that it grew well in broth media, whereas Weichselbaum's diplococcus did not grow at all or very slightly in such media. In the period, July, 1899, to August, 1900, there have been 17 cases of this disease in the medical wards at Great Ormond-street, or at least diagnosed as such, in 12 of which the diagnosis was verified by post-mortem examination. Of the remaining five patients two recovered; in two leave to make an examination was refused, and the fifth contracted diphtheria while in the ward and was transferred, owing to pressure upon our available beds, to the fever hospital. These cases, as will be seen later, do not all of them correspond to the

ordinary type of the disease, four of them being children much older than the average age, which Barlow and Lees state as 11 months.

List of Cases.

No. of case.	Age.	Result.	Remarks.
1	2 years.	Death; necropsy.	No bacteriological examination made.
2	5 months.	,, ,,	No bacteriological examination made.
3	4 ,,	,, ,,	Diplococci in exudate; no cultivations.
4	9 ,,	,, ,,	Diplococci in exudate and in cultivations.
5	4 years.	,, ,,	Diplococci in exudate and in cultivations.
6	11 months.	,, ,,	Nothing found in exudate; cultures sterile.
7	4 years.	,, ,,	Diplococci in exudate and in cultivations.
8	4 ,,	Recovery.	—
9	4 months.	Death; necropsy.	Diplococci in exudate; no cultivations.
10	8 ,,	,, ,,	No bacteriological examination made.
11	6 ,,	,, ,,	Diplococci in exudate and in cultivations.
12	8 ,,	Death; no necropsy.	—
13	9 ,,	Discharged *in statu quo*.	—
14	3 years, 6 months.	Recovery.	—
15	4 months.	Death; necropsy.	Diplococci in exudate; no cultivations.
16	1 year, 4 months.	,, ,,	Diplococci in exudate and in cultivations.
17	8 months.	Death; no necropsy.	—

Bacteriology.—Of the 12 cases in which a post-mortem examination took place three were not examined bacteriologically; in two cases the post-mortem examination was performed in my absence, and in the third the brain was hardened and preserved. In the remaining nine cases the meningeal exudation was examined by means of films of lymph taken from the collection at the base of the brain and from the lateral ventricles. An intracellular diplococcus was discovered in eight of these cases; in the ninth no organism of any description could be found. In all cases the diplococcus appeared to be the only organism present; no streptococci or pneumococci were discovered. In six cases cultivations were made on agar-agar and glycerine-agar media. Five of these proved successful, the diplococcus growing, however, scantily in all cases. The unsuccessful case was that in which microscopical examination had shown an absence of organisms; in this instance nothing grew upon the culture media. In Case 4 a lumbar puncture was performed during life, and the fluid was inoculated upon gar-agar. This gave a fairly typical growth of the diplococcus. Thus out of the nine cases examined in eight the diplococcus intracellularis was demonstrated in the exudate, and in five of these it was found in cultivations, being present in pure culture in four; the fifth was, I believe, accidentally contaminated, for it contained, besides typical colonies of the diplococcus, large growths of staphylococcus pyogenes aureus and streptococcus pyogenes.

Vitality.—The vitality of the organism in the meningeal exudation would seem to be very variable. Thus in one patient dying on the forty-second day of the disease it was found very scantily in the coverslips examined and grew in the culture-tubes in very few colonies, while in two other patients dying respectively about three months and eight months after the onset of the disease it was found in considerable profusion; in the second of these, however, it is possible that the patient died in a second attack, or a recrudescence of the original infection. In cultivations the organism did not live; in one case sub-cultures made from a 48-hours growth proved quite sterile, and in no case did there appear to be any vitality left in the colonies at the end of a week. Looking at Dr. Still's results I feel sure that mine are not trustworthy in this point, probably because the inoculations were not made with sufficient freedom; further, I have not employed a blood-agar medium, on which he found the organism to persist longest. In Case 4 the fluid obtained by lumbar puncture during life gave a fair growth of the organisms, but at death 15 days later there were very few colonies indeed in the cultivations, and I had to hunt through several films before discovering typical diplococci, so that the organism had apparently lost much of its vitality between the twelfth and the twenty-eighth days of the disease.

This question of the vitality of the organism is, of course, one of great importance, for Weichselbaum's diplococcus isolated from epidemic cerebro-spinal cases was stated by its discoverer to be possessed of extremely limited powers of endurance, while Dr. Still found that the diplococcus of posterior basic meningitis lived an average of three weeks, and, as he remarks, this difference is by far the most striking. In other points the two observers for the most part agreed. It is therefore interesting to note my failure in these cases to obtain a prolonged vitality and also Netter's statement, quoted from Dr. Osler's Cavendish Lecture of 1899, that Weichselbaum's diplococcus has been found living at the end of 60 days. On the whole it seems most probable that the organisms are practically identical, though apparently with slightly different qualities according as they occur in epidemics or sporadic cases.[1] I have had no opportunity of seeing any epidemic of the disease, though one of the series of cases in its clinical aspect approached more nearly to the epidemic type, as described by Osler, than to the chronic disease with which I am familiar.

Clinical features.—In this series 10 of the cases occurred in males and seven in females. Of the age at which the disease made its appearance it is noticeable that four of the 17 patients were in their fourth year and over, a much larger proportion than Sir Thomas Barlow and Dr. Lees found. In their series of 110 cases seven only were as old. It may also be observed here that these four cases all gave rise to considerable difficulty in diagnosis, and that two of them were cases that recovered, so that absolute proof of the correctness of the diagnosis is wanting. Excluding these four the average age of the patients attacked was nine months, the youngest being just three months old. The previous history and the family history of these cases bear out the statement of Barlow and Lees that there is no other affection which bears any constant relation to this disease. In the majority of cases it appears without any previous ill-health either in the patient or in those who surround him.

As regards the first symptom of the disease this series corresponds exactly with the analysis given by Sir Thomas Barlow and Dr. Lees. Vomiting occurred first in nine cases, convulsions in four, and head retraction in three. Bulging of the fontanelle is noted early in the course of the illness in six cases. Retraction of the head is one of the cardinal signs of the disease, and sooner or later appears in all cases. It occasionally, however, appears too late to be of much service in diagnosis and in two of these cases, Cases 1 and 5, it was not noted at any time. Further, there has been in the hospital during the period of time covered by this series a boy, aged 10 months, in whom retraction of the head to an extreme degree was constant, though at the necropsy there was no trace whatever of meningitis. It is also worthy of remark that this symptom was well marked in only one of the four older cases, whereas it was obvious in all but one of the remainder.

Ocular symptoms.—Strabismus was a fairly frequent and early symptom, as also was nystagmus, occurring in about half the cases; but the chief ocular symptoms, with one exception to be mentioned later, are to be sought by means of the ophthalmoscope, for 13 of these 17 cases showed definite changes in the fundus. In five cases there was pronounced swelling of the optic discs, which was very easily recognised and indeed could not be overlooked; in one of these there were in addition several flame-shaped retinal hæmorrhages. In four cases there was a peculiar grey discolouration of the optic disc, which appears to me to be peculiar to this disease. At any rate, I have never met with anything similar in any other illness. It is not atrophy, I venture to think, for the retinal vessels retain their normal size, and the disc does not appear hollowed, but it has an unusual opaque grey appearance quite unlike a normal disc. In the remaining four cases the changes were

[1] Since the above was written I have been successful in maintaining the vitality of the diplococcus up to the thirty-eighth day, at which period subcultures proved sterile.

such that I have not ventured to call them papillitis, yet they are of that nature. In looking at these eyes with the ophthalmoscope regularly week by week, the optic discs which were at first absolutely normal became slowly more and more obscure, and in focussing accurately one could see that at the edge the finer vessels took a sharp curve, so that there was obviously some swelling, rarely more than 1 D, of the papilla, though the edge of the disc still remained distinct. This change, I believe, might easily have been overlooked if the discs had not been frequently examined.

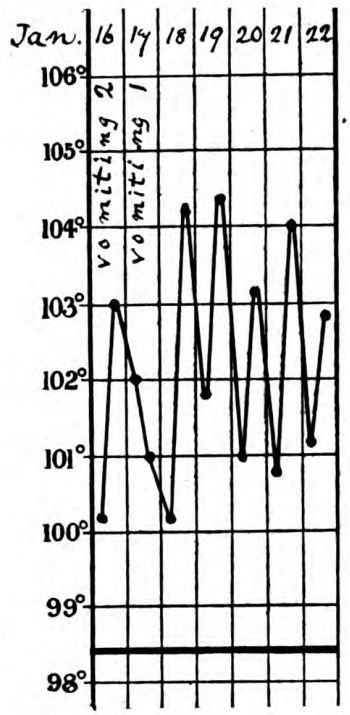
Amaurosis was noted in seven cases and was probably present in several others, but it is a symptom which is extremely difficult to ascertain with precision in young infants. The other important ocular symptom mentioned previously is retraction of the upper eyelid which occurred in seven of these cases. It is extremely characteristic of posterior basic meningitis, and, so far as I have been able to observe, extremely rare in any other form of meningitis. It is certainly very uncommon in tuberculous meningitis, for I can neither recollect nor find any record of its occurrence in the 26 cases of that disease which have occurred in the given period. Indeed, one might venture on an antithesis: in tuberculous meningitis there is photophobia and closure of the eyes, while in posterior basic meningitis the eyes are widely open with retracted upper lids as if seeking the light.

The other chief features of the disease—vomiting and progressive emaciation—were present in all cases, though in six cases the vomiting was slight. The emaciation was always pronounced and rapid even in the two patients who recovered, and apparently it is largely independent of any vomiting or diarrhœa that may be present, for in cases where these are absent the emaciation still progresses steadily. One month's duration will reduce the patient to mere skin and bone, in striking contrast to cases of tuberculous meningitis, which are not infrequently found possessed of considerable quantities of subcutaneous fat at the necropsy. The remaining features of the disease are with one or two possible exceptions those which are common to nearly all forms of meningitis; and though in nearly all of them there is some special point, which I believe to be to a certain extent indicative of the special form, yet these points are too uncertain to permit of any stress being laid on them. Thus there are the "champing" movements of the lips and jaws described by Sir Thomas Barlow and Dr. Lees, which are certainly more commonly seen in this form of meningitis than in any other, and yet are sufficiently often observed in tuberculous meningitis to render them devoid of any diagnostic significance. Hyperæsthesia of the skin, on the other hand, is distinctly more common in the tuberculous than in the posterior basic form. There are, however, two phenomena observed in the latter which do not, I believe, occur in the former. These are hydrocephalus and a joint affection. Hydrocephalus, of course, in a pathological sense is present in most cases of meningitis of whatever form, but in a few cases of posterior basic meningitis the head enlarges progressively and post mortem there is a very considerable excess of fluid. In only one, however, of the present series was there a clinical hydrocephalus. Careful measurements of the size of the head from time to time failed to show any enlargement. The joint affection has been fully investigated by Dr. Still who cultivated from the pus in the joints the same diplococcus which he found in the brain. None of the present series have had any joints involved.

It will be obvious from the foregoing brief summary of the symptoms that the diagnosis in the majority of cases is easy. The sudden onset, the characteristic head retraction, the chronic course, and the progressive emaciation render the disease, as a rule, easily recognisable. Yet of the present series seven of the cases presented difficulties more or less serious. The patient in Case 1 was supposed at one time to have a cerebral tumour, a diagnosis supported by the extensive optic neuritis and retinal hæmorrhages, combined with the absence of any head retraction. The necropsy showed the typical lesions of posterior basic meningitis and no trace of tumour formation. Case 5 was diagnosed confidently as a case of tuberculous meningitis, and the discovery of the true condition at the post-mortem examination was a surprise. Typhoid fever was suspected in Case 7 and Case 12, and in Case 4, Case 8, and Case 14 the diagnosis was delayed for some time. Three of these cases are worthy of a little further consideration.

CASE 7.—A girl, aged four years, previously in good health, was taken suddenly ill with headache and a "fit" on Jan. 8th, 1900. On the 9th she had a smart epistaxis. On admission on the 16th she was feverish, irritable, and decidedly ill, but apart from a slight stiffness in the cervical muscles had no sign of disease. Her temperature chart (Chart 1) was

CHART 1.



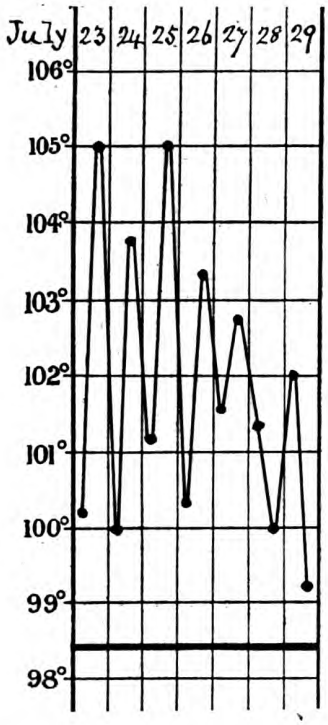
remarkably unlike that usually associated with posterior basic meningitis, in which disease, as a general rule, the temperature remains below 100° F., with occasional rises at very irregular intervals. It was not till two days before her death that the diagnosis was made with any certainty, though retraction of the eyelids had been noted on Feb. 2nd, a fortnight earlier. In this case typhoid fever was suspected, but repeated trials of Widal's serum reaction all proved negative. The course of the fever, the absence of any positive physical signs of disease, and the age of the patient all, I venture to think, combined to make earlier diagnosis impossible.

With this case Case 4 is comparable. This was a girl, aged nine months, who was brought to the hospital for diarrhœa and vomiting which began on July 16th, 1900. She was admitted on the 23rd and the only objective sign of disease was a slight stiffness of the neck and some retraction of the head, which had completely disappeared three days later. In this case the results of a cultivation made from the fluid obtained by lumbar puncture established the diagnosis at the end of the first week; but without this aid it would not have been possible to be sure of one's ground until the middle of the following week when the clinical picture was characteristic. The temperature chart (Chart 2) has at least a family resemblance to that of the preceding case.

The third case was, if possible, still more puzzling. A boy, aged eight months, was taken suddenly ill with "convulsions" on Dec. 31st, 1899. These were repeated on Jan. 1st and 2nd. He was admitted on Jan. 3rd and no diagnosis was made till near the end of the third week. Typhoid fever was again suggested and several other diagnoses were discussed. The child had no objective signs of disease except the fever and a slight rigidity of the cervical muscles. At the end of the third week, however, he presented the typical retraction of the head, and the subsequent course of the illness confirmed the diagnosis then made. His temperature chart (Chart 3) again illustrates a wide departure from the ordinary course of the disease.

As regards the temperature in these cases it is significant that they were all three admitted before the end of the first week of the illness. The majority of the cases come to the hospital much later, and it is possible that if they could be seen at an earlier period such charts would be far more common than they are at present. It is particularly interesting to compare the first two of these charts with that given by Dr. Osler in his Cavendish lecture, numbered Chart 4. That was obtained from one of the cases occurring in an outbreak of epidemic cerebro-spinal meningitis and the resemblance to the type here illustrated is extraordinarily close.

CHART 2.

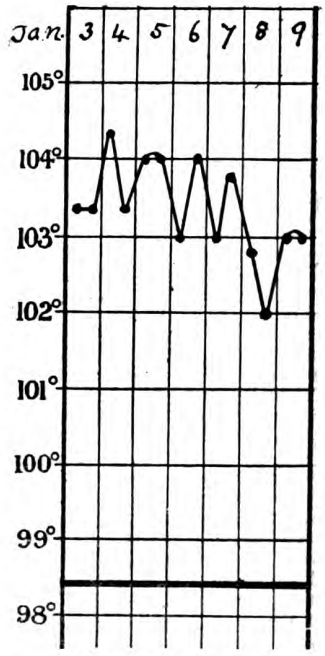


CASE 8.—This case was that of a boy, aged four years, and ended in recovery. He was admitted with a history of a sudden onset of vomiting and head retraction nearly a month previously. He had slight retraction of the head, well-marked optic neuritis, hyperæsthesia of the skin, and retracted abdomen with a well-marked tâche. He was quite conscious and even intelligent. His temperature was intermittent with a range of from four to five degrees for a week and then became very unsteady. Towards the end of the third week it became normal and he went out a few days later quite well. I have seen this patient three months later; he is very healthy and his intelligence seems in no way impaired. He still has a slight blurring of the optic discs, but there is no swelling, no loss of vision, and no evidence of atrophy.

The patient in Case 14, the other patient who recovered, has, I am afraid, left the country. He came over with his father from South Africa soon after the outbreak of the war, was suddenly taken ill with "convulsions" about Jan. 30th, 1900, and was admitted three weeks later. This case corresponded almost exactly in its clinical symptoms to the description given of epidemic cerebro-spinal meningitis, but was, so far as we were able to learn, quite an isolated case. He had irregular pyrexia, marked head-retraction, slight strabismus, marked hyperæsthesia, great irritability, and much tremor. He was never wholly unconscious, but he always knew his relations and even made efforts to speak to them. He had marked optic neuritis also and was the only patient in any one of these cases who had any skin eruption, having herpes covering both legs, portions of the thighs, and the lower part of the abdomen. His temperature came down rather suddenly to normal in the sixth week of his illness and remained there. The boy was discharged quite well at the end of the ninth week.

Before leaving the question of the diagnosis of the disease there are a few negative points to be mentioned. Blood-counts were made in several of the cases and in the early stages of the disease there was always a considerable leucocytosis; in the more chronic forms the white corpuscles have regained their normal standard. Of the different forms of meningitis the posterior basic form certainly in its active stage gives rise to a higher leucocytosis than tuberculous, but I have not yet had an opportunity of comparing it with pure pneumococcic meningitis. Kernig's sign, the rigid contraction of the flexors of the thigh, is, I believe, present in nearly all cases of posterior basic meningitis It is, however, present also in cases in which there is no cerebro-spinal meningitis. I have recently found it well marked in two cases of lateral sinus thrombosis in which post mortem there was no meningitis at all. Lumbar puncture was used only once and then as a diagnostic measure. It is, to judge from the reports of our American and Canadian visitors, largely employed as a therapeutic measure in the United States and Canada, and with success. Osler, however, found that his epidemic cerebro-spinal cases derived no benefit from the procedure, and his experience seems to coincide with that of others. It is obviously quite useless late in the disease, and the only time at which removal of the cerebro-spinal fluid would appear to have any possible benefit is during the first week. It is possible that if tried only in cases which have not yet passed the seventh day from the onset the results may be more encouraging, and at any rate in such a disease any means of benefit is worthy of trial. All treatment of other kinds seems quite inefficacious, and pending the discovery of an antitoxin, lumbar puncture in a selected class of cases seems to hold out some faint promise. At the same time, it must be admitted that the pathological lesions found at the post-mortem examination are usually of such a character and in such situations that drainage by the spinal canal seems a wholly futile measure.

CHART 3.



In conclusion, it will be obvious from the foregoing account that posterior basic meningitis presents a considerable variety of clinical characters. In the majority of the cases which occur in children of under 12 months it is a very distinct and easily recognisable disease, but this rule does not hold invariably. On the other hand, a disease occurring in older children with many of the same symptoms and possessing the same pathological and bacteriological features, yet has certain characteristics which make it resemble very closely epidemic cerebro-spinal meningitis. Are the two identical, and are the special features of the epidemic disease

due merely to an exaltation of virulence in the organism? On the whole, and judging from the cases which I have seen, which unfortunately include no epidemic cases, I think the answer must be in the affirmative. The clinical symptoms obviously differ considerably without any corresponding alteration in the pathological or bacteriological features, and the main differences between the organism of Weichselbaum and the organism found in these cases in England seem to be quite insufficient to establish them as distinct species. If this view is accepted we shall henceforth look upon posterior basic meningitis as a disease comparable in certain points to pneumonia, which, while as a rule a sporadic disease, occasionally presents itself in epidemic form. The causes which determine this variation are in both cases still to be discovered. I have to thank Dr. Lees, Dr. Penrose, and Dr. Garrod for permission to make use of the cases which have occurred in their respective wards; and I also owe thanks to Dr. Still for much help and many suggestions.

Bentinck-street, W.

PRIMARY SARCOMA OF THE STOMACH

BY W. SOLTAU FENWICK, M.D., M.R.C.P. LOND.,
PHYSICIAN TO THE EVELINA HOSPITAL FOR SICK CHILDREN, ETC.

DURING the last few years the opinion has been steadily gaining ground that many of the morbid growths of the stomach which have hitherto been regarded as carcinomata are really sarcomatous in character and that the clinical description of malignant disease of the viscus requires to be revised from a new pathological standpoint. This opinion is founded partly upon the discovery that many specimens which are described in museum catalogues as examples of carcinomatous or fibroid tumours present the characteristic features of round-cell or spindle-cell sarcoma when examined with the microscope, and partly upon the large number of cases of sarcoma of the stomach which have been published since special attention was directed to the subject. Thus, Perry and Shaw found four instances of sarcoma among 50 specimens of malignant disease of the stomach, while in the course of 23 consecutive necropsies upon persons who had died from primary neoplasms of the organ I observed two well-marked examples of round-cell sarcoma. It may also be noticed that whereas Schlesinger in 1897 was only able to collect 30 cases of the disease, in November, 1900, the number of published cases exceeded 60, of which 53 possessed sufficient details to permit of analysis. Although it is impossible to make any absolute statement as to the relative frequency of the disease it is probable the sarcomata constitute from 5 to 8 per cent. of all primary neoplasms of the stomach.

Gastric sarcoma may appear either as a primary growth or as a secondary deposit. The former is by far the most common if exception be made of those not infrequent cases where the organ is involved by a lympho-sarcoma Six varieties of the primary affection have been described up to the present time—namely, round-cell sarcoma, spindle-cell sarcoma, fibro-sarcoma, myo-sarcoma, myxo-sarcoma, and angio-sarcoma. Of these the spindle-cell and the fibro-sarcomata are probably identical, while the single example of myxo-sarcoma appears to have been originally a case of the round-cell type which had undergone degeneration.

MORBID ANATOMY.

1. *Round-cell sarcoma*.—Round-cell sarcoma, or as it is often termed "lympho-sarcoma," is the variety most usually met with and was observed in 33 out of 53 cases, or in about 62 per cent. of the entire number. As a rule it presents itself in the form of a dense infiltration of the pyloric third of the stomach, which transforms the coats of this portion of the viscus into a homogeneous, yellowish-white mass of rigid consistence and considerable thickness. The peritoneal aspect is often covered with recent lymph, while the inner surface may be slightly uneven or distinctly nodular and is occasionally superficially ulcerated. If the pylorus is greatly thickened its orifice may be partially stenosed, as in cases of spheroidal-cell carcinoma, but as a rule the rigidity of its tissues renders it patent and the valve incompetent rather than contracted. The growth gradually shades off as it approaches the centre of the organ, but it is often prolonged for some distance along the curvatures in the form of thick striæ or bands. In almost every instance, whether the pylorus is stenosed or not, the cardiac portion of the stomach is dilated and its mucous membrane shows signs of chronic inflammation. In about one-sixth of the cases the entire organ was infiltrated by the new growth, which also tended to invade the first part of the duodenum and the lower end of the œsophagus. The walls of the viscus were greatly thickened and its cavity contracted, and its inner surface was sometimes extensively ulcerated. In only two instances out of the entire number did the disease appear as a circumscribed tumour in the wall of the viscus, with secondary nodules in the surrounding mucous membrane. On microscopical examination the disease is found to commence as a round-cell infiltration of the sub-mucosa, which subsequently spreads into the muscular coat through its interstitial connective tissue and finally destroys and replaces the contractile fibres. At first the mucous membrane is merely stretched by the subjacent growth and atrophies from pressure, but at a later stage it is often invaded by the disease and may undergo ulceration. Schlagenhaufer and Redtenbacher have shown that a diffuse infiltration of round cells in the mucous membrane may extend far beyond the apparent confines of the disease. Like the other forms of sarcomata, this variety is prone to undergo softening and degeneration, with the formation of small cavities in its substance or perforation of the wall of the stomach.

2. *Spindle-cell or fibro-sarcoma*.—This comes next in frequency of occurrence and constituted 12 out of the 53 cases, or 22 per cent. It presents itself as a round or oval circumscribed tumour of the wall of the stomach and it is usually situated near the great curvature. As it grows it projects more and more beneath the serous coat and exerts so much traction upon its point of origin that it not only drags the whole stomach downwards but often acquires a pedunculated appearance. These tumours sometimes grow to an enormous size (12 lb., Cantwell), and may fill the greater part of the abdominal cavity. When small they are smooth and firm on section, but as their bulk increases they often become knotty and irregular in shape, and their tissue undergoes cystic degeneration. These latter changes are seldom accompanied by the formation of adhesions, but occasionally give rise to perforation of the stomach (Ewald).

3. *Myo-sarcomata*.—These are much rarer than either of the preceding, only five examples having been recorded up to the present time. They form smooth or slightly nodular masses in the substance of the gastric wall near the great curvature and frequently show signs of cystic degeneration. Like the fibro-sarcomata, they may attain enormous dimensions, Brodowski having met with one which weighed 12 lb.

4. *Angio-sarcoma*.—This has been recorded twice (Bruch and Kosinski). In one case it formed a tumour of the size of an infant's head with many cysts due to interstitial hæmorrhages scattered through its substance.

Each variety is apt to give rise to secondary growths in organs more or less remote from the primary disease, but the round cell is by far the most malignant. Thus out of 23 cases of the latter in which full details are given, 16 or 70 per cent. are stated to have exhibited metastases. In almost every instance the lymphatic glands immediately connected with the stomach were enlarged and in nearly 50 per cent. they were sarcomatous; while in a few cases the retro-peritoneal, mesenteric, and even the mediastinal, cervical, and supra clavicular glands were affected. One or both kidneys presented secondary deposits in 28 per cent.; the liver, ovaries, pancreas, adrenals, and omentum each in 14 per cent.; and the lungs, diaphragm, pleuræ, œsophagus, intestines, and mesentery in about 7 per cent. of the cases. It is also important to notice that nodules of growth were present in the skin of the abdomen, thorax, or back in about 12 per cent. of the entire number. The spindle-cell variety was accompanied by metastases in the perigastric glands in 37 per cent. of the cases, and in the skin, liver, and diaphragm in about 12 per cent. of the cases, while in two out of the five cases of myo-sarcoma secondary growths were found in the liver.

A further study of the morbid phenomena of gastric sarcomata brings to light several other points of distinction between them and the carcinomata which may prove of service in their clinical differentiation. Owing to the infrequent infection of the peritoneum there is usually a notable

absence of the elongated and nodular epigastric tumour which is so often present in cancer of the stomach, owing to infiltration and adhesion of the great omentum. Again, in about 15 per cent. of the cases of round-cell sarcoma the spleen is so much enlarged as to project below the costal margin. This increase in size is not due to the existence of a morbid growth in its substance, but to congestion and hyperplasia of the splenic pulp—a condition which never occurs in carcinoma. Kundrat observed enlargement of the tonsils with occasional swelling and ulceration of the follicles of the tongue, and laid considerable stress upon their diagnostic significance. Perforation of the stomach followed by general peritonitis occurs far more often than in cases of cancer (11 per cent.), owing probably to the frequent softening of the morbid growth and to the absence of protective adhesions. On the other hand, localised perigastric abscess has not been observed up to the present. Death from hæmorrhage has only been recorded once (Robert), and in one instance the disease gave rise to a gastro-colic fistula (Chernjaeff). True carcinoma was twice found associated with round-cell sarcoma.

Secondary sarcomata of the stomach are usually lympho-sarcomatous in their nature and have been observed as the result of disease in the retro-peritoneal glands (Maier, Perry), cæcum (Beck), neck, pharynx, gums (Kundrat), rectum, superior maxilla, and in cases of general sarcomatosis (Malmsten, Carry). When the mischief spreads by contiguity the pyloric region is often affected in the same manner as in the primary affection, but when the original growth is more remotely situated the metastases usually appear as rounded tumours or thick wheals in the submucous tissue. These deposits often soften and ulcerate and may even undergo partial cicatrisation.

ETIOLOGY.

At present there are few facts that bear directly upon the etiology of the disease. The round-cell sarcoma seems to affect both sexes with equal frequency and to develop at any age. Nevertheless, there is a distinct tendency for it to occur at an earlier period of life than carcinoma, since the mean age of 29 cases was only 34 years. The spindle-cell variety, on the other hand, is five times as frequent in women as in men, the average age of the collected cases at the time of death being 51 years. The one recorded by Finlayson of sarcoma in a male child, three and a half years old, appears to be an exception to this rule, but the description of the microscopical features of the tumour is somewhat vague. The myo-sarcomata were usually met with in men in the prime of life. That a sarcoma, like carcinoma, is prone to attack scar-tissue in the stomach is well illustrated by a case published by Brooks, where a round-cell growth developed in the cicatrix of an old bullet wound of the lesser curvature. In a case which came under the writer's observation a large secondary melanotic growth was found in the base of a simple chronic ulcer situated near the pylorus.

SYMPTOMS.

The general symptoms of sarcoma of the stomach are essentially the same as those which accompany other forms of malignant disease. One of its earliest and most striking features is progressive emaciation with failure of physical power. This is usually most conspicuous in young persons and in cases where the growth causes early contraction of the pyloric orifice. When the neoplasm only affects a comparatively small portion of the viscus, as in the spindle-cell and myo-sarcomata, the loss of flesh is chiefly observed in the later stages of the complaint or after ulceration has taken place. Anæmia is always present and gradually becomes profound, but if there is continued fever or repeated hæmorrhage its progress is very rapid. It is characterised by a great diminution both of hæmoglobin and red corpuscles and in one of the cases recorded the colouring matter only amounted to 15 per cent. of the normal. Slight leucocytosis may sometimes be observed, but the increase of white corpuscles which normally occurs after meals (digestion-leucocytosis) is usually absent. As a rule the appetite is greatly diminished and there is a special distaste to meat, but occasionally the desire for food continues unimpaired throughout (Rasch, Baldy) or only declines during the last few weeks of life (Maass, Fleiner); thirst varies with the severity of the anæmia. When the neoplasm grows very rapidly or its tissues undergo degenerative changes the patient often exhibits slight but continuous pyrexia (from 99° to 101° F.). Albuminuria occurs in about one-sixth of the cases and is usually dependent upon secondary growths in the kidneys. If vomiting is a prominent feature of the case the bowels may be confined, but in many cases of the round-cell type diarrhœa is a noticeable feature.

With regard to the local symptoms which accompany sarcoma of the stomach it should be noticed in the first place that they may be entirely absent during the whole course of the disease. In the case related by Baldy the appetite continued good and there was no complaint either of pain or vomiting, although practically the entire stomach was involved in an enormous tumour. In another instance (Cantwell) where the growth weighed 12 pounds the digestive functions were apparently normal, while in that recorded by Robert the first and only indication of an extensive growth was an attack of hæmatemesis. In about 76 per cent. of all cases abdominal pain is experienced during some period of the disease. It varies greatly, however, both in its character and severity. As a rule it does not amount to more than a sense of fulness and oppression after meals such as ensues from gaseous distension of the stomach, but in 15 per cent. of the recorded cases it was described as having been severe and increased by the ingestion of food. It is interesting to observe that in most of these the body of the stomach was either extensively infiltrated or there was a considerable invasion of the pancreas or retro-peritoneal glands. The solid tumours (fibro- and myo-sarcomata) are more often accompanied by sensations of weight or dragging than by actual pain.

Vomiting is usually a later symptom unless the pylorus is contracted. At first it occurs at intervals, but as the stomach becomes dilated it is repeated more frequently and the ejecta are found to present the usual features which characterise stagnation and decomposition of the food. Vomiting occurring soon after meals and preceded by pain usually indicates ulceration of the growth, while the attacks of incessant retching, attended with the expulsion of mucus, which are apt to appear from time to time, and are often so severe as to preclude the administration of food, result from secondary inflammation of the mucous membrane. In the case of the large solid tumours vomiting is a less frequent phenomenon (48 per cent.) and seldom appears until after the lapse of from five months to seven months. Fæcal vomiting is usually an indication of a gastro-colic fistula.

Hæmorrhage from the stomach is seldom a prominent symptom of round-cell sarcoma owing to the comparative infrequency of ulceration of the growth. It is probable, however, that capillary oozing is of constant occurrence, since the gastric contents removed by a tube are often found to be mixed with coffee-ground material, while careful examination of the stools may demonstrate the existence of altered blood (Schlesinger). In the spindle-cell variety of the disease repeated attacks of hæmatemesis were observed in nearly half the cases, and in two instances a severe hæmorrhage was the first symptom to attract attention.

PHYSICAL SIGNS.

A palpable tumour connected with the stomach is an inconstant sign of round-cell sarcoma and was only observed in about 30 per cent. of the recorded cases. In most instances it is produced by a local thickening of the gastric wall in the region of the pylorus, and was described as a round or oval mass, occupying the right hypochondriac or epigastric region, smooth on the surface, somewhat tender upon pressure, and often freely moveable. Rapid increase in size can sometimes be observed. In other instances the tumour consists of the entire stomach and more than once the concomitant enlargement of the spleen has been mistaken for a malignant mass. In the fibro- and myo-sarcomata a tumour is almost always present and is often so large as to occupy the greater part of the abdominal cavity. If the growth is situated near the great curvature it is usually detected in the umbilical left hypochondriac or lumbar region, where it forms a smooth, firm, painless mass which is dull on percussion and freely moveable in all directions. This latter peculiarity affords a marked contrast to the behaviour of a carcinomatous growth in the same position, which is invariably fixed by extensive adhesions to the neighbouring viscera. In two cases where the tumour was attached to the posterior wall of the stomach it filled the lesser sac of the peritoneum and was consequently covered by the stomach and transverse colon, but being somewhat pedunculated it could easily be moved from side to side.

Dilatation of the stomach can be detected in every case of sarcoma of the pylorus, and when the orifice is contracted peristaltic movements of the enlarged viscus are usually visible. When the organ is affected by diffuse infiltration its cavity is contracted and its outlines are obscured by the transverse colon.

Metastatic deposits in the skin constitute an important feature of the disease. As a rule they appear in the form of one or two small nodules in or around the umbilicus, but occasionally they are very numerous and are scattered all over the abdomen, chest, and back. They vary in size from a millet seed to a small bean, and at first are freely moveable in the subcutaneous tissue; but after a time they become adherent to the skin and may even give rise to ulceration. Enlargement of the supra-clavicular and cervical glands is rarely observed, while sarcomatous infiltration of the tongue is still less common. In one case a correct diagnosis was made by the discovery of a secondary growth in the rectum. Generalisation of the disease is occasionally accompanied by the symptoms of purpura (Redtenbacher).

Chemical examination of the contents of the stomach affords similar results to those met with in gastric cancer. Free hydrochloric acid disappears at an early stage of the complaint (Fleiner, Schlesinger) and fermentation of the food often produces an excess of lactic acid (Dreyer, Maass, Hammerslag). Sarcinæ may or may not be present and Schlesinger was able to demonstrate the presence of the Oppler-Boas bacillus which is supposed to occur only in cases of cancer. The sulphocyanide of potassium in the saliva gradually diminishes as the disease progresses and finally disappears about one month before death.

DURATION AND COMPLICATIONS.

It is difficult to estimate the exact duration of a disease which commences so insidiously and is often unaccompanied by definite physical signs for many months. It would appear, however, from a study of the recorded cases that although the round-cell sarcomata often run their course in three or four months the average duration of the disease is about 15 months; while in the case of the spindle-cell and myo-sarcomata life is prolonged on the average for two years and eight months. It will be observed that in both instances the duration of the disease is greater than that of cancer, a result which probably depends upon its lesser malignancy and its lesser liability to produce ulceration of the mucous membrane and stenosis of the pylorus. Death usually occurs from exhaustion and is often preceded by a semi-comatose state lasting for several days. Perforation of the stomach followed by general peritonitis occurs in about from 10 per cent. to 12 per cent. of the cases of round-cell sarcoma and may even take place in the spindle-cell form (Ewald), but owing to the absence of adhesions a perigastric abscess is exceptional. Fatal hæmorrhage is very rare. In two instances general sarcomatosis tended to shorten the period of life, while in one an attack of tetany, similar to that met with in cicatricial stenosis of the pylorus, was immediately responsible for the fatal termination (Fleiner). Excessive ascites, albuminuria, portal thrombosis, and pneumonia all accelerate the natural course of the disease.

DIAGNOSIS.

So far as the recognition of the malignant nature of the disease is concerned the sarcomata do not offer any particular difficulty. The intractable character of the gastric symptoms, coupled with the progressive emaciation, physical debility, and cachexia, indicate a profound disturbance of the processes of digestion and assimilation, while the discovery of a growing tumour connected with the stomach or of metastases in other viscera demonstrates at once the existence of a neoplasm. A more interesting question is the clinical differentiation of sarcoma and carcinoma. A diagnosis of round-cell sarcoma of the stomach may often be made by attention to the following facts:—1. The disease usually occurs before 35 years of age, so that the younger the patient the greater the probability that the malignant affection is sarcomatous in character. 2. In many cases there is slight but continuous pyrexia accompanied by rapid and profound anæmia, while in carcinoma fever is always absent during the early stages of the complaint and the cachexia much more gradual in its development. 3. Simple enlargement of the spleen is by no means infrequent, but is never met with in cancer unless the organ is involved in the growth. 4. According to Kundrat the tonsils are apt to enlarge and the follicles upon the sides of the tongue may become swollen or ulcerated. 5. Secondary deposits in the skin occur in a notable proportion of the cases and permit of excision and microscopical examination. It should be remembered, however, that sarcomatosis has been met with in true cancer of the stomach (Leube). 6. A large nodular tumour due to infiltration of the omentum or a greatly enlarged liver with secondary growths in its substance are rarely met with. 7. Persistent albuminuria is often observed in sarcoma but is exceptional in cancer. 8 The discovery of pieces of morbid growth in the vomit renders the diagnosis certain (Riegel, Westphalen).

The spindle-cell and myo-sarcomata are chiefly characterised by their comparatively slow growth, the smooth, firm, and moveable tumour, the frequent absence of pain, vomiting, and anorexia, and the tendency to repeated hæmorrhage.

TREATMENT.

Many of the recorded cases have been subjected to surgical treatment with considerable success so far as the immediate objects of the operation were concerned. Török, Dock, Schopf, and others have removed considerable portions of the stomach affected by the round-cell growth, and in at least one case (Schopf) there was no recurrence at the end of a year. The solid tumours are especially favourable for extirpation, as they are often pedunculated and involve a comparatively small area of the gastric wall. Hartley removed a large fibro-sarcoma and Kosinski a cystic angio-sarcoma with apparent success, while in Cantwell's case the excision of spindle-cell sarcoma weighing 12 lb. gave great relief to the patient for eight months. If one may judge from the morbid anatomy of the disease the surgical treatment of sarcomata of the stomach will prove far more successful than can ever be expected in carcinoma, but it is too early yet to discuss the prospects of a permanent cure.

FOREIGN BODY IN THE ABDOMEN.

BY ERNEST H. ELLISON, M.A., M.R.C.S. ENG., L.R.C.P. LOND.

As illustrating the importance of the well-known axiom that all instruments and sponges should be counted prior to performing operations in the interior of the abdomen I append the following case which occurred in my practice recently.

A man, aged 49 years, sent for me in consequence of severe pain which he referred to the region of the umbilicus. This on examination proved to be due to the presence of a foreign body which protruded through the integuments about three inches below and to the left of the umbilicus. All efforts to remove the foreign body without a cutting operation—to which the patient refused his consent—being futile I succeeded in breaking off the most dependent portion of what on inspection presented the appearance of being the blades

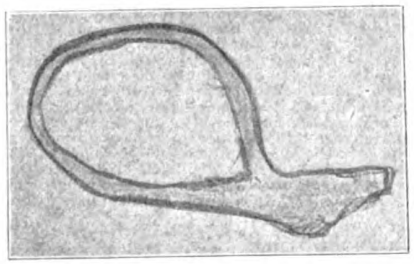
of a pair of catch forceps. The button portion uniting the blades was clearly visible, one half of the blades showing what I presume to be corrosion from the action of the intestinal juices upon it, and judging from the worn and eaten appearance of the extremity of one of the blades this must evidently have occurred. The fact of a foreign body of the above description having been discovered in the situation described points to an omission on the part of some practitioner to count his instruments prior to performing an abdominal operation eight and a half years ago—this being the period of time, according to the patient, since an operation was performed upon him for an internal strangulation. The statement seems probable enough from the presence of a clearly defined scar situated above Poupart's ligament in the right inguinal region.

FIG. 1.

Shows the first part of the forceps removed. Exact size.

I may, in conclusion, add that there is every evidence of the remaining part of the forceps being still in the cavity of the abdomen; and meanwhile, in the hope that I may one day obtain the patient's consent to remove the shaft and handles of such an instrument, I annex a photograph showing the exact size of the portion in my possession.

FIG. 2.



Shows the second part of the forceps removed. Exact size.

P.S.—Since forwarding to you the above article I have been fortunate in obtaining last week another portion of the instrument of which I inclose a rough sketch (Fig. 2).

Syston, Leicester.

A CASE OF CEPHALHÆMATOMA.

BY HUGH HOWIE BORLAND, M.B., C.M. GLASG., D.P.H. CANTAB.,

DISTRICT PHYSICIAN TO THE GLASGOW MATERNITY HOSPITAL.

ON April 23rd, 1900, I was called to the third accouchement of a woman, aged 33 years. The first labour pain came on at 10.30 P.M.; two pains ruptured the membranes with the escape of liquor amnii. On my arrival two hours later I found the os fully dilated. There was no pelvic contraction or deformity. Presentation was first cranial. One strong pain set in bringing the head right on to the perineum. Forceps were not used. The labour (two and a half hours) was rapid but easy throughout. The child cried lustily when born. I saw the infant washed and it looked natural and healthy. The scalp showed no caput succedaneum or other evidences of pressure. The shape and size of the head appeared normal in every way and with no trace of injury. The nurse, eight hours later, however, observed that the head had become swollen on both sides. I found next day a somewhat rounded circumscribed swelling over the right parietal bone raised up at and bulging over the lambdoidal suture posteriorly and limited anteriorly by the fronto-parietal suture. The elevated bulk of the tumour was over the posterior and superior angle of the parietal bone. Over the left parietal region was found another swelling smaller, more diffusive, less elevated, and not circumscribed. On the second day the child's face was pale and waxy, the lips and conjunctivæ were anæmic, and the skin was devoid of the newly born healthy rosy colour. The two swellings had still further increased in size, the head presenting a characteristic bicornate square appearance from the superimposed tumours which occupied the greater part of the two parietal bones respectively. The right tumour exceeded the left in length by one and a half inches. Both swellings were fuller and more rounded at the outer aspect with a gradual symmetrical tapering flatness towards the sagittal suture, giving rise to a V shaped depression running antero-posteriorly. The scalp area, normally situated over the posterior fontanelle, was deviated fully one inch outwards and forwards; neither the lambdoidal suture nor the posterior fontanelle could be demarcated. The right tumour had a reddish tint with no discolouration; it was slightly tense, rounded, circumscribed, and fluctuant, not increased in size when the child cried; its volume was not diminished on pressure, nor were stupor, coma, or convulsions induced, but several occipital glands were enlarged from pressure on the lymphatics. There was also distinct protrusion of the anterior fontanelle. On the third day the presence of a bony circle could be made out at the periphery of the right tumour limiting the effusion; discolouration over this tumour had now supervened. The left tumour had no red tint and no fluctuation obtained. No bony circle was found but the tumour pitted on pressure. Icterus neonatorum developed. On the fourth day there was an extension of ecchymosis over the swelling, which was smaller, less tense, but more fluctuant. The contour of the head had assumed a more natural shape. The left tumour subsequently decreased more rapidly than the right and was at no time discoloured; the œdematous pitting suggested epicranial cephalhæmatoma while the tumour on the right was obviously sub-pericranial. On the fifth day the protrusion over the anterior fontanelle had disappeared but the sulcus in the median line was still well marked. On the twelfth day the right swelling was greatest over the parieto-temporal region and was still dark in colour and glazed. No effusion crossed the sagittal suture but the great veins were now engorged and prominent. By the eighteenth day the right tumour was only half the size it presented on the third day, measuring now five inches antero-posteriorly and transversely four inches. The left tumour disappeared entirely on the twentieth day, while the right persisted till June 2nd, 40 days after birth, when all swelling of the scalp had vanished.

During the first week the child shivered and trembled occasionally. There was no development of strabismus or paralysis. The treatment was entirely passive, and it was noteworthy that the presence of these tumours was seen to be quite compatible with the health of the child with the exception of anæmia and constipation. The child slept well and fed well. There was no elevation of temperature, no dyspnœa, and no cerebral complications. There was no history of hæmophilia, but the other children are very fair and I can only suggest that there may have been tenuity of the walls of the blood-vessels and that rupture of these occurred when a portion of the head was constricted by the os uteri and thus eventually led to the effusion of blood which I have described.

Glasgow.

FREEMASONRY.—*The Rahere Lodge, No. 2546.*—An ordinary meeting of the Rahere Lodge, No. 2546, was held at Frascati's Restaurant on Feb. 12th, W. Bro. Walter Gripper, M.B., W.M., in the chair. Bros. Hepburn and Bokenham were raised to the third degree, and Bros. Ware, Whitaker, and Beadles were passed to the second degree. A grant of 15 guineas was made to a professional brother in urgent distress, a donation of one guinea was given to the maintenance of "Our Brother's Bed" in the Home for the Dying, and a sum of 20 guineas was voted to the Royal Medical Benevolent College at Epsom, on the proposition of W. Bro. E. C. Cripps. In consequence of the much-lamented death of Her Majesty the Queen there was no banquet after the meeting, but a few members of the Lodge dined together informally.

PRIMARY CARCINOMA OF THE AMPULLA OF VATER, WITH REPORT OF A CASE PRESENTING SOME SPECIAL FEATURES OF INTEREST.

By H. D. ROLLESTON, M.A., M.D. CANTAB., F.R.C.P. LOND.,
PHYSICIAN AND LECTURER ON PATHOLOGY AT ST. GEORGE'S HOSPITAL; SENIOR PHYSICIAN TO OUT-PATIENTS, VICTORIA HOSPITAL FOR CHILDREN.

NORMALLY, before opening into the duodenum, the common bile duct and Wirsung's duct of the pancreas open into a common channel inside the biliary papilla. This short duct is called the ampulla or diverticulum Vateri. Normally its mucous membrane is rougher and more villous than that of the common bile duct, but the so-called ampulla of Vater is little, if at all, larger than the common bile duct except when pathologically dilated by an impacted gall-stone. Carcinoma may start in the mucous membrane lining this ampulla of Vater, as in the case I record in this paper. Carcinoma may spread into the ampulla from the lower end of the bile duct and possibly from the termination of Wirsung's duct. In a paper on primary carcinoma of the larger bile ducts published in 1896 I came to the conclusion that most cases of so-called carcinoma of the ampulla of Vater originated in the termination of the common bile duct;[1] later in the year R. Durand-Fardel[2] showed a specimen supporting this and adopted the same view. The clinical aspects of the two are identical and the histological structure of the growths in the two situations is the same—viz., a columnar-celled carcinoma. Their pathological effects, however, may differ; thus carcinoma of the ampulla of Vater may obstruct Wirsung's duct and so lead to cystic dilatation with fibrosis of the pancreas, while carcinoma of the termination of the common bile duct is not so likely to do this. Pic[3] regarded carcinoma of the ampulla of Vater as an aberrant form of pancreatic carcinoma corresponding apparently to the excretory type (columnar-celled) of pancreatic carcinoma described by Bard and Pic.[4] This is practically saying that carcinoma of the ampulla of Vater is carcinoma of the termination of the pancreatic duct. While admitting that carcinoma might spread to the ampulla of Vater from the termination of the common bile duct or from Wirsung's duct, Hanot[5] insisted on the occurrence of primary carcinoma starting in the lining membrane of the ampulla and has described two cases. He spoke of it as "cancer du pylore pancréatico-biliare," and instanced it as an "orificial cancer."

Primary carcinoma of the ampulla Vateri, or, as it might more conveniently be called, the choledocho-pancreatic duct, must be also distinguished from primary carcinoma attacking the mucous membrane covering the duodenal surface of the biliary papilla. Specimens of this form of duodenal carcinoma are to be found in the museums of St. Bartholomew's, Guy's, and St. Thomas's Hospitals. This lesion seems to be especially prone to lead to infective cholangitis and intra-hepatic suppuration. Carcinoma of the ampulla of Vater must thus be distinguished from carcinoma (1) of the termination of the common bile duct; (2) of the termination of Wirsung's duct; and (3) of the duodenal surface of the biliary papilla. The accompanying diagram illustrates these distinctions. Confusion may also occur between carcinoma of the head of the pancreas and primary carcinoma of the ampulla Vateri. Histologically they differ; carcinoma of the pancreas is spheroidal-celled, while carcinoma of the diverticulum Vateri is columnar-celled.

It may be difficult to decide where the growth started when the tumour has had time to spread and invade adjacent parts. Thus in some instances doubt will arise whether the tumour arose in the lower end of the bile duct, in the ampulla of Vater, or in the head of the pancreas. In forming a decision from a naked-eye examination in such cases it may be pointed out that carcinoma of the ampulla of Vater may, when of considerable size, project as a tumour through the gaping lips of the biliary papilla and be visible in the duodenum; this is not met with in carcinoma of the pancreas or of the termination of the common bile duct.

The clinical characters of primary carcinoma of the ampulla of Vater are the same as those of primary carcinoma of the common bile duct—viz., progressive jaundice and wasting, the patient finally passing into a condition of cholæmia or biliary toxæmia. It thus very closely resembles cases of carcinoma of the head of the pancreas. The only difference is that jaundice is exceptionally absent in malignant disease of the head of the pancreas. The treatment has so far been palliative except in one case where Halsted[6] successfully removed a columnar-celled carcinoma

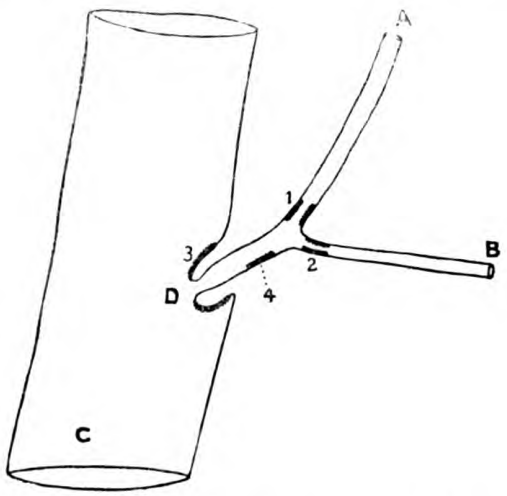


Diagram of the ampulla Vateri, showing the various situations where carcinoma may arise in relation with it and in its neighbourhood. A, Common bile duct. B, Wirsung's duct. C, Duodenum. D, Biliary papilla. 1. Carcinoma of the termination of the common bile duct. 2. Carcinoma of the termination of Wirsung's duct. 3. Carcinoma of the duodenal surface of the biliary papilla. 4. Carcinoma of the ampulla Vateri itself.

of the ampulla of Vater, but the growth recurred in the head of the pancreas and in the duodenum, and proved fatal within a year of the operation. Busson,[7] in 1890, collected 11 cases of carcinoma of the ampulla, and in 1896 Vincent-Georges,[8] a pupil of Hanot, added nine more; later in the same year Hanot[9] described another case. Of these 21 reported cases about seven are above suspicion; most of the remainder are either carcinoma of the termination of the common bile duct or of the duodenal surface of the biliary papilla. It is, therefore, a rare condition. The following case is recorded as an example of primary carcinoma of the ampulla Vateri with some special points of interest.

Carcinoma of the ampulla Vateri; dilated common bile and Wirsung's ducts; death from hæmorrhage into the dilated duct of Wirsung.—A man, aged 66 years, was admitted into St. George's Hospital under my care on July 22nd, 1900, with jaundice, pruritus, weakness, and wasting. Ten weeks previously he had considered himself quite well, jaundice then appeared quite painlessly, and a month later he got weaker and felt drowsy; six weeks after the onset of jaundice the skin began to itch. There was no history of gall-stones. When examined on admission he was deeply jaundiced and the skin showed the effects of scratching; the liver was enlarged, reaching to the fourth rib above and extending two and a half finger-breadths below the costal arch in the right nipple line, the surface was smooth, and the gall-bladder could be indistinctly felt. No splenic enlargement could be made out. There was some abdominal distension but no ascites. There was tenderness at a spot over the eleventh and twelfth ribs in the right hypochondrium. Per rectum nothing but an hypertrophied prostate could be felt. The urine contained albumin and bile but no sugar. The

[9] Loc. cit.

patient had been sent up to the hospital as a case of cancer of the liver; it appeared probable, however, that the growth was in the head of the pancreas. On July 25th there was some diarrhœa; on July 26th he vomited, had a rigor, and the temperature fell to 96° F., the pulse was small, and he was collapsed. The abdomen moved well and it appeared unlikely that perforation of the gall-bladder from over-distension, as in a case recorded by Coats and Finlayson,[10] had occurred. Suppuration around the gall-bladder was thought of, but his condition precluded any surgical treatment and he was given morphia. Death occurred 18 hours after the onset of acute symptoms.

At the *necropsy*, performed by Dr. W. J. Fenton, the peritoneal cavity showed no recent peritonitis but contained two parts of bile-stained fluid. A flat growth was found limited to the ampulla of Vater and occluding the orifices of both the common bile duct and the duct of Wirsung. This growth was not visible from the duodenum and was only seen when the papilla was opened up. Microscopically the growth was a columnar-celled carcinoma and was found to be invading the smooth muscular tissue around the ampulla Vateri. The common bile duct was greatly dilated with dark bile and was as thick as one's thumb. When the finger was introduced into the duct and directed downwards towards the biliary papilla the common duct was felt to end blindly like a test tube. The hepatic, cystic ducts, and the gall-bladder were greatly dilated; no gall-stones were found. The liver weighed 4 lb.; it was enlarged, smooth on the surface, and deeply bile-stained. Microscopically there was no cirrhosis, though the atrophied and degenerated condition of the liver cells allowed the existing fibrous tissue of the portal spaces to appear more prominent than in health. Wirsung's duct was tortuous and dilated throughout the whole of the pancreas; in the head of the gland there was a large cystic dilatation of the duct which contained recent blood-clot; the rest of the dilated duct contained dark brown fluid. No calculi were seen. The tail of the pancreas was adherent to the stomach by old adhesions, evidently the result of past inflammation. To the naked eye the pancreas was extremely fibrotic. Microscopically the glandular tissue of the organ was widely replaced by fibrous tissue and, where it could be made out, was much disorganised. Numerous dilated ducts were seen, some of which contained microscopic calculi. There was some recent small cell infiltration. The stomach and intestines showed signs of recent catarrhal inflammation. The kidneys presented senile changes and a few cysts. The heart weighed 11 ounces and was normal for the time of life. The lungs were emphysematous. No secondary growths were found in any part of the body.

The additional points of interest are:—1. The sudden onset of acute symptoms, followed by death in 18 hours. The preliminary diarrhœa, taken in conjunction with the signs of catarrhal inflammation found after death, make it probable that an infective gastro-enteritis set up inflammation in the chronically inflamed pancreas, and that acute pancreatitis, with the resulting hæmorrhage into the dilated duct, accounted for the severe collapse and death. 2. The extremely fibrotic condition of the pancreas appeared to be too advanced to be accounted for by obstruction of 11 weeks' duration. It is probable that, if the chronic pancreatitis was due to obstruction of Wirsung's duct, the growth must have interfered with the duct of Wirsung for a considerable period before it set up biliary obstruction. 3. It is noticeable that with such extreme fibrosis of the pancreas there was no glycosuria or diabetes.

Upper Brook-street, W.

ON THE USES OF FORMALIN IN GLYCERINE.

BY ALFRED C. JORDAN, B.A., M.B., B.C. CANTAB., L.R.C.P. LOND., M.R.C.S. ENG.,
HOUSE PHYSICIAN, ST. BARTHOLOMEW'S HOSPITAL.

FORMALIN is so powerful an antiseptic that its use for clinical purposes has tempted many, but in every case, so far as I know, the attempt has been abandoned on account of the irritating nature of formalin and the pain which its use has involved. I have found that this difficulty can be to a great extent overcome by using glycerine instead of water as the medium by which to convey the formalin to the required part. For 10 months I have used a mixture of formalin in glycerine, from 1 to 4 per cent. Although the mixture will keep without much diminution in strength for several weeks in a well-stoppered bottle in a cool place, it is better to prepare it fresh for use each time by mixing from one and a half to five minims of formalin with two fluid drachms of pure glycerine. This preparation is useful in at least four different ways—(1) as an application to the throat; (2) as a mouth-wash; (3) as an application to the skin; and (4) as a urethral injection.

1. *As an application to the throat.*—An ordinary pharyngeal brush is employed. A single application can be absolutely relied upon to kill every micro organism with which it comes in contact. My bacteriological examinations prove this. The glycerine spreads readily over the surface beyond the immediate limits of its application; it conveys the formalin into the follicles of the tonsils and into the deep layers of the mucous membrane. In follicular tonsillitis in the early days, while there are no deep collections of pus, formalin in glycerine (2, 3, or 4 per cent.) is a specific. After a single thorough application the temperature falls to normal within a few hours, and remains normal. The application is usually attended by a little soreness lasting only a few hours. For from half an hour to an hour after the treatment the patient should not be allowed to drink, the formalin being left undisturbed to exert its bactericidal action. After this a simple gargle, such as chlorate of potash, is all that is necessary. In diphtheria, in cases where the membrane is confined to the pharynx, formalin in glycerine is equally successful. In most cases, however, there is membrane in situations inaccessible to a brush: in the nares or in the air-passages In such cases formalin in glycerine is of little use. In scarlet fever, where the throat condition is but a small part of a general disorder, one cannot expect much good from formalin; but even here 2 per cent. of formalin in glycerine every second or third day is certainly as good as any other local application with which I am acquainted.

2. *As a mouth-wash.*—In aphthous stomatitis and in parasitic stomatitis (thrush) a single application of formalin in glycerine, 2 per cent., should be made, and followed by the use of the glycerinum acidi borici of the British Pharmacopœia. In ulcerative stomatitis a single application does not appear to do much good and I am not convinced that formalin always accelerates the healing of the ulcers to an appreciable extent. Combined with iodine and with β eucaine (the latter as a local anæsthetic) in the following proportions, a useful mouth-wash is afforded: 1 per cent. of formalin, 2 per cent. of iodine, and 2 per cent. of β eucaine, in glycerine. With this and the internal administration of chlorate of potash good results are obtained. In gangrenous stomatitis (cancrum oris) I have not had an opportunity of trying formalin, but I believe that at the commencement 4 per cent. formalin in glycerine might penetrate sufficiently deeply to put a stop to the disease. Tuberculous ulcers of the pharynx, mouth, tongue, and lips, occurring as they do in the broken-down subjects of advanced phthisis, are never hopeful cases to treat. They are always liable to re-infection from the lungs and therefore repeated applications are necessary. But these repeated applications are not well tolerated on account of the great tenderness of the ulcers. In one case of tuberculous ulcer of the lower lip I was able to apply 4 per cent. formalin in glycerine very thoroughly twice a week by previously placing in contact with the ulcer a piece of absorbent wool soaked in β eucaine 4 per cent. In the intervals the ulcer was protected as far as possible by boric ointment. Considerable improvement occurred by the end of a fortnight, but I was not able to keep the patient under observation.

3. *As an application to the skin.*—Formalin may be thus employed in all parasitic diseases, but especially in tinea tonsurans (ringworm). The whole area is thoroughly cleaned by means of turpentine, followed by soft soap and water to remove grease, and 4 per cent. formalin in glycerine is rubbed carefully in by means of a piece of lint soaked in it. If there is much inflammation a piece of lint soaked in the formalin and glycerine is simply applied to the surface and left so for a few hours, protected by a layer of wool. This application never requires to be repeated. A little boric or zinc ointment or lead lotion will complete the cure in a few days. I have never known this to fail. Some cases of lupus ought to be readily curable by a few applications of 4 per cent. formalin in glycerine on lint. I have not yet, however, had opportunities of testing this important point.

[10] Glasgow Medical Journal, vol. xxxiv., August, 1890.

4. *As a urethral injection.*—In one case of acute gonorrhœa I injected one and a half drachms of 1 per cent. formalin in glycerine, with the result of completely and permanently curing the case. But for three days after the injection there were considerable pain and difficulty of micturition, due, no doubt, to swelling of the mucous membrane. For this reason I am not confident in recommending its general use as a urethral injection.

Other uses of formalin in glycerine will doubtless suggest themselves to the reader.

St. Bartholomew's Hospital, E.C.

MATERNAL IMPRESSIONS IN LOWER LIFE.

BY ANDREW WILSON, F.R.S. EDIN., &c.

RECENT articles in THE LANCET have directed attention anew to the subject of maternal impressions. I am one of those who believe, on scientific evidence, of the possibility of the state of the mother mentally and otherwise affecting the fœtus. Therefore the following incident may prove interesting to biologists and medical men at large.

In a letter dated from Port Elizabeth, South Africa, and dated Dec. 15th last, a correspondent, Mr. David Lumsden, gives the case of a kid taken from a bush-bock ewe (*Tragelaphus sylvaticus*) killed in the "elephant bush" distant about 40 miles from Port Elizabeth. In this district numerous elephants are found. The kid (Fig. 1) of which a photograph was inclosed in the letter of my correspondent, is seen to possess an elephantine head and proboscis, while the tail is also of the proboscidean rather than of the antelope type. By way of comparison I have reproduced the antelope itself (Fig. 2) from the drawing in Wood's "Natural History." If one may suppose that the pregnant ewe was frightened by an elephant the deformity of the kid may be explained—that is, if we admit the possibility of maternal impressions acting on the unborn young. Teratologists may be able to refer the deformity to some type or other independently of such an explanation, but if the maternal impression view be adopted the human element, which is credited with explaining things on the *post hoc* principle, must of course be entirely eliminated from such a case as that before us. In other words, there is here no anxiety about the young before birth

FIG. 1.

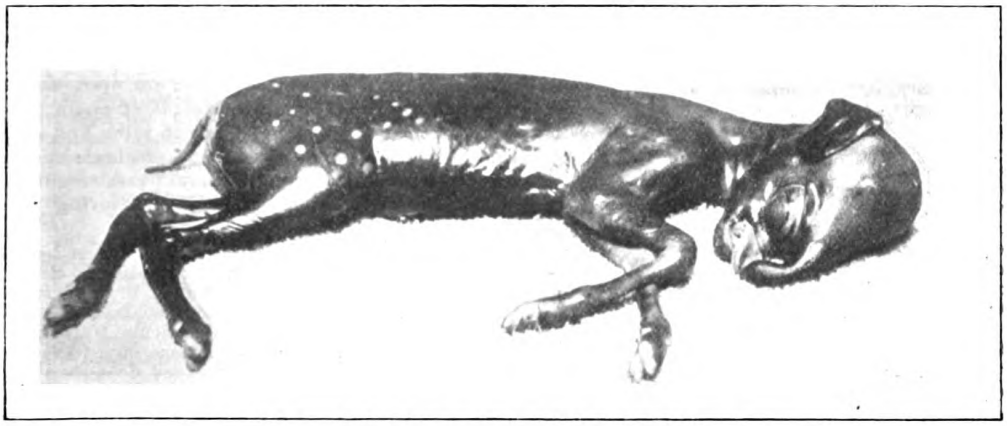

FIG. 2.

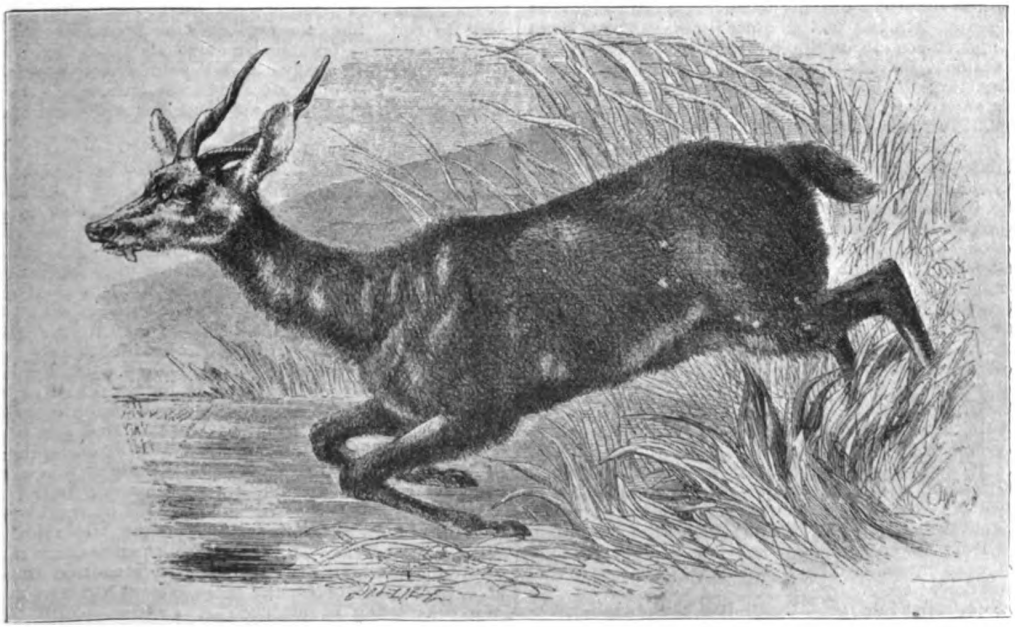

and no discounting beforehand how the young might be deformed in consequence of some real or supposed fright or injury received by the mother.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Procemium.

CHILDREN'S HOSPITAL, BIRMINGHAM.

A CASE OF CYSTINURIA WITH FORMATION OF CALCULI.

(Under the care of Mr. GAMGEE.)

THE presence of cystin in the urine may always be taken to indicate the occurrence of an abnormal breaking down of albumin, either in the alimentary canal, as in most cases, or in the tissues of the body, as occurs in acute yellow atrophy of the liver. Cystin calculi are usually single, but occasionally, as in Mr. Gamgee's case, many of these calculi may be present.

A boy, aged 12 years, was admitted into the Children's Hospital, Birmingham, on Oct. 20th, 1900, complaining of the frequent passage of calculi per urethram. The patient was sent into the hospital by Dr. E. A. Sadler of Ashbourne, who has supplied many details of the history.

The family history showed that the patient comes of a long-lived family. His paternal grandfather died at the age of 63 years from heart disease. His paternal great-grandfather died when he was 80 years of age from "stoppage of the water," but there is no history of there having been a vesical calculus present. His paternal grandmother is still alive, aged 70 years, and is always in good health. The patient's father has six brothers and four sisters, all alive and well. The grandfather and grandmother on the mother's side are still living; they are over 70 years old and are always well in health. There is no history in the family of phthisis, gout, or rheumatism, except that a sister of the patient's mother died, when she was 21 years old, her relatives saying that at the time of her death she was "a bit consumptive." The patient's father and mother are alive and well.

As regards the patient's personal history he had bronchitis during his first dentition and his tonsils have been enlarged for some years. He has had no other illness. There is no point of importance about the patient's diet. Two years ago the patient, for the first time, passed a small stone per urethram, and he has done this four times since, passing one stone each time. The father and mother are quite certain that the stones passed on these occasions were quite different from those passed a few days before the boy was admitted into the hospital, for they were very gritty, were yellow in colour, and had a rough surface. During the week previously to admission the patient passed eight small calculi, the passage of them being very painful and causing retention of urine. These stones are very small, are yellowish-white in colour, have a smooth surface, and together weigh two grains. The quantity of urine passed in 24 hours varied from 34 to 44 ounces and the quantity of urea varied from 374 to 484 grains. There was neither albumin nor sugar present. On standing the urine deposited a slight sediment, which was found to contain many typical hexagonal crystals of cystin.

On Oct. 23rd the patient was sounded and another calculus was found. This, after being removed by suprapubic cystotomy, was found to weigh eight grains and to be oval in shape. Its surface was in one part exactly like those of the smaller calculi already described, but the greater part of the surface was covered with glistening yellow crystals. The patient made a good recovery after the operation. Scrapings from the calculi were dissolved in ammonia solution. On evaporation of the liquid hexagonal crystals of cystin were deposited.

Remarks by Mr. GAMGEE.—Cystinuria is undoubtedly in some cases hereditary, but in this instance the family history has been inquired into very carefully and no trace of the affection in other members of the patient's family has been met with. At times, too, cystinuria is present in patients who either are themselves the subjects of tuberculosis or who come of a tuberculous family, but here again in the case now under review the history is negative. Urine containing cystin is said to decompose rapidly and to contain only a small amount of urea, but rapid decomposition was not noticed in this case and, as has been stated, the amount of urea passed was well up to the average. The parents' statement as to the character of the calculi previously passed is curious. The passage of cystin calculi usually recurs at intervals, and it seems unlikely that this patient passed calculi sometimes of cystin and sometimes of some other material. The causation of cystinuria is obscure, but the condition is probably due to the presence in the intestines of certain specific micro-organisms producing an abnormal decomposition of proteid matter.

DEVIZES HOSPITAL.

A CASE OF PERFORATED GASTRIC ULCER WITH OPERATION AND RECOVERY.

(Under the care of Dr. H. MACKAY.)

THE manipulations necessary for the suture of a perforated gastric ulcer on the posterior wall near the cardiac orifice are much facilitated by an additional incision of the abdominal wall towards the left ribs; yet even with this the operation is never easy. All records of operation for perforating ulcer of the stomach are of value and enable more exact ideas to be formed as to the diagnosis and treatment of this condition. Dr. Mackay's case recorded below illustrates the value of sponging in removing the effused gastric contents.

A domestic servant, aged 17 years, was seen by Dr. G. C. Phillips on the afternoon of Nov. 23rd, 1900. She was very ill and complained of severe pain in the epigastrium and right hypochondrium. She had been faint and violently sick. The pain had come on suddenly while she was at work about one o'clock on the same day. With the pain came a sudden feeling of faintness and sickness and then she collapsed on the floor. Her previous history revealed that she had suffered from anæmia and gastric pain for nearly twelve months and that she had been under treatment for gastric ulcer in the preceding April. Hæmatemesis and melæna were denied. During the few days preceding the present attack she had not felt worse than usual. On the evening immediately preceding it she had gone home and had a "good" supper of cold roast pork, after which she went to bed. She was awakened an hour later by pain in the epigastrium, but she went to sleep again. All the following morning she had gastric pain, which was increased by her breakfast of bread-and-butter and tea. As already stated she was at her work about one o'clock when the attack occurred for which advice was sought.

Dr. Phillips found her in a condition of collapse, with a pale, anxious face, shallow, jerky breathing, a small rapid, weak, irregular pulse, and cold surfaces and extremities. The pain, which was acute, was referred to the epigastrium and left hypochondrium, from which it extended up the left side almost to the axilla. The tongue was foul. The bowels had acted the day before without difficulty. The temperature was 99° F. Physical examination showed a hard resisting abdomen with slight distension, some tenderness in the region to which the pain was referred, and a tympanitic note over the whole abdomen with complete absence of liver dulness. A diagnosis of perforated gastric ulcer was made by Dr. Phillips, and the patient's removal to the hospital was recommended. On subsequent examination at the hospital, the same physical signs being present, it was decided, with the concurrence of Dr. Phillips and Dr. A. V. Trow, to operate at once.

The extremities and trunk of the patient being swathed in warm Gamgee tissue the abdomen was opened by a three-inch incision in the middle line between the xiphi-sternum and the umbilicus. On dividing the peritoneum a gush of turbid fluid and gas occurred and the presence in the fluid of minute oil globules like those present on the surface of soup was taken as evidence of gastric contents in the

abdominal cavity. The stomach and intestines were considerably distended with flatus. The anterior wall of the stomach was first examined, but with negative results. The lesser curvature was next explored and on its posterior aspect in the neighbourhood of the œsophageal opening a round hole was found from which gastric contents were escaping. Its position, as near as could be judged, was about a couple of inches from the insertion of the œsophagus. Its edges were clean cut and its diameter was about seven or eight millimetres. It was situated in the centre of a dense round mass of cicatricial or inflammatory deposit which occupied the entire thickness of the gastric wall. The wall was here of considerable thickness. The area of thickening extended for a distance of about one and a half cubic centimetres around the margin of the ulcer in all directions and over this area the visceral peritoneum was tightly adherent to the subjacent tissues. The contents of the stomach having been squeezed out through the perforation three fine silk sutures were passed as a preliminary measure through the margin of the opening. Such was the density of the surrounding tissues, however, that on several occasions these sutures tore through in the endeavour to approximate the edges of the ulcer. Two ridges of peritoneum were then picked up as near the perforation as the adhesion of the membrane would permit and an inclosing "tuck" between five and six centimetres in length was brought together by a dozen Lembert sutures. The abdominal cavity was then methodically wiped out with warm sponges wrung out of sterilised water and the gastric contents were as far as possible removed. The various recesses in the neighbourhood of the spleen and kidneys were explored, but it was found impossible to wipe out the cul-de-sac between the antero-superior surface of the liver and the diaphragm. The apposing surfaces were here in such close contact, probably owing to upward pressure from the distended intestines, that a sponge could not be passed without the risk of bruising or abrading the surface of the liver. Considerable compunction of conscience resulted, too, from the fact that it was impossible to perform any kind of toilet of the lesser peritoneal sac, notwithstanding the presumption that some of the escaped gastric contents might have lodged there. Access to this region by the route of the lesser curvature was clearly impossible. The cavity might certainly have been reached and cleansed by dividing the two anterior layers of the great omentum, but this was a step which at the time did not commend itself to Dr. Mackay. No flushing was made use of. Gauze drains were placed leading to the antero-superior surface of the liver and to the site of perforation; the peritoneum was drawn together by interrupted sutures of fine gut and the abdominal parietes with stout gut. A space was left in the middle of the wound for the emergence of the gauze drains. Dry dressings were applied and equable pressure was secured by a many-tailed bandage.

With the exception of flatulence, abdominal symptoms were inconspicuous after the operation. The drains, which remained sweet, were removed on the fifth day and the sutures on the tenth day, when the incision was soundly healed. From the tenth to the twenty-first day the temperature was normal and the patient was comfortable. There then appeared an irregular pyrexia, with an evening rise to 100·4°, slight respiratory acceleration, and cough. These signs heralded the appearance of a patch of dulness with friction sounds over the middle of the lower lobe of the left lung. Frequent exploration with the needle gave only a little bloody serum for result. Finally, on the twenty-ninth day, the temperature rose suddenly to 103·6°, and a purulent expectoration, at first fairly copious, set in. This continued for four days, then as it gradually declined in quantity the temperature fell to normal and the cough ceased. The course of events suggests that there was a localised septic infection of the diaphragmatic pleura conveyed through Recklinghausen's lymph channels from the sub-diaphragmatic area of infection in the neighbourhood of the perforation. Pus formation on the pleural side appears to have ensued, with subsequent evacuation of the same through the bronchial tubes. Symptoms suggestive of pus formation on the peritoneal side were not apparent, and the further progress of the patient was rapid and uninterrupted.

Remarks by Dr. MACKAY.—Probably every case of operation for perforated gastric ulcer, successful or otherwise, ought to be reported at the present time for purposes of criticism and of statistics. This consideration is the reason for recording the above case, in which the points worthy of notice appear to be the following:—1. The fortunate conditions which rendered possible a prompt diagnosis and an early operation, the patient being on the table within four hours from the moment of perforation. 2. The technical difficulties which attend an operation in this region of the stomach. While an area on the anterior surface or the greater curvature is easily reached and is easily brought into the operation wound and under the hands of the operator, one on the posterior surface is reached with difficulty, and one in the neighbourhood of the œsophageal opening must be dealt with more or less *in situ*, the attachment of the œsophagus preventing any traction towards the surface. In this case the necessary manipulations were carried on at the bottom of a pit which shelved upwards under the shadow of the xiphi-sternum. 3. The probable occurrence of a direct transmission of septic infection through the lymph channels of the diaphragm, giving rise to a purulent accumulation on the pleural side, without any signs suggestive of pus formation on the peritoneal side.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Adjourned Debate on Arsenical Beer Poisoning.

A MEETING of this society was held on Feb. 12th, Dr. F. W. PAVY, the President, being in the chair.

Dr. E. S. REYNOLDS (Manchester) illustrated by projections of photographs of patients the leading symptoms in order of time: (1) congestion of the conjunctiva; (2) congestion and œdema of the face and legs; (3) erythromelalgia; (4) papular erythema (the face, the arms, and the back); (5) deeper dermatitis simulating late secondary syphilis; (6) herpes zoster; (7) pigmentation of various kinds and degrees—deep general, mulatto-like, punctiform, patchy, &c.; (8) unpigmented scars in generally pigmented skin; (9) pigmentation with furfuraceous desquamation; (10) keratosis; (11) bullæ; (12) transverse furrows of the nails; and (13) purpura (rare). Other photographs illustrated the first onset of paralysis which is evidenced by inability to appose the thumb and little finger, and a case of total paralysis of the diaphragm. Dr. Reynolds also showed (for Professor Delépine) photographs of crystals of As_2O_3 obtained by Reinsch's test from solutions of 1 in 1,000,000 in water and 1 in 100,000 in beer (standardised) and from commercial beer, glucose, and sulphuric acid.

Dr. DIXON MANN (Manchester) pointed, with regard to the clinical features, to some unusual types that occurred in the epidemic: (1) cases without neuritis or skin lesions, but with perspiration, mental apathy, and a tendency to rambling, weak heart, and œdema of the lungs, freedom from pain, fever of from 1° to 3°, and a tendency to sudden death from syncope; and (2) cases marked by tendency to collapse and absence of fever, diarrhœa, vomiting, weak heart, and tendency to syncope, as in subacute poisoning from arsenic. In the former type a diagnosis of enteric fever had been made; in the latter symptoms might be deferred for from four to seven days after the patient had ceased taking arsenical beer. In the matter of chemical observations, arsenic hitherto had been regarded as a non-cumulative poison. He (Dr. Mann) had shown that half an hour after taking five minims of arsenical solution the metal could be detected in the urine. In fatal acute poisoning arsenic was not as a rule detected when the patient had survived for from 14 to 16 days. It appeared that prolonged administration delayed elimination, although, unlike lead or other metals, arsenic did not form stable combinations with tissue proteids. Thus, in the modified conditions of this outbreak arsenic was a cumulative poison. Time was not the only factor. In one case in which a woman who had died 21 days after admission to hospital had been removed from the source of poisoning no arsenic was found post mortem, while in the case of another woman who in the same circumstances survived 52 days arsenic was found. The primary channels of elimination were the kidneys, but the importance of the skin as a secondary channel was very great. He had obtained 0·8 milligramme of As_2O_3 from 10 grammes of keratosis tissue. The nails contained appreciable quantities

of arsenic. As to elimination without symptoms Dr. Mann had found in some surgical patients who drank beer that a considerable amount of arsenic was eliminated by the urine as though no symptoms of arsenical poisoning were present.

Dr. JUDSON S. BURY (Manchester) thought that the nature of cases of slight pigmentation must now be more closely investigated. He believed that he had seen peripheral neuritis in spirit-drinkers. There was in his experience no outbreak similar to the recent one. He had never before seen such severe hyperæsthesia in the limbs. The hyperæsthesia was very persistent, remaining months after the keratosis or the paralysis. In some cases pain and effusion of the joints and tenderness of the bones were observed. He thought the paralysis was more widespread in the arsenical than in most other forms of peripheral neuritis. In the hand the paralysis of extension was marked and it led to a curved shape of the fingers.

Dr. NATHAN RAW (Liverpool) said that the outbreak did not appear to have been so extensive in Liverpool as in Manchester. During the last three years out of 12,623 patients admitted to the Mill-road Infirmary 226 had alcoholic neuritis; of these 147 presented symptoms attributable to arsenic. Of the 226 patients 51 died from cardiac failure and general asthenia. From his statistics he concluded that the contamination of beer commenced in May, 1900. Beer and porter appeared to be the usual vehicles. He had observed very little peripheral neuritis in Scotland. The serious lesions, he thought, were due rather to continued drinking of moderate quantities than to sudden outbursts of deep drinking. Among the symptoms marked pyrexia was present in three cases. He found arsenic in the urine in five cases out of 33 examined, but in no case was he able to find it later than 10 days after admission. Dr. Raw referred to the observation made by Osler to the effect that liquor arsenicalis when given in brandy had more effect than when given in water alone.

Dr. T. N. KELYNACK showed illustrations, photographs, and casts of numerous cases. The casts showed the late effects. He believed that the alcoholic "vehicle" in the form of beer accentuated the toxic effect of arsenic. He had observed cases in infants at the breast, and this pointed to elimination in milk. He thought the presence of As_2O_3 in glucose was associated with an acid reaction. The amount present in different samples of beer varied. In one instance there were 1 4 grains of As_2O_3 in the gallon.

Sir LAUDER BRUNTON referred to John Hunter's experiments on dogs. Hunter found that when dogs were poisoned by placing arsenious acid in a wound they died just as surely as when the poison was swallowed, and after death there was evidence of inflammation of the stomach in both cases, but it was more marked when the poison was absorbed from a wound than when it was taken by the mouth.

Dr. A. P. LUFF had for some years taught that where peripheral neuritis of doubtful origin was present arsenic was to be suspected. The elimination of arsenic in ponderable quantities as described by Dr. Dixon Mann was really a new fact. In one case he (Dr. Luff) had given an adult five minims of arsenical solution three times a day for a short time when suddenly peripheral neuritis set in. It then transpired that the patient was an alcoholic subject. He took notes in 40 cases in Manchester and found that there had been vomiting and colic in only 36 per cent., and these were cases where large quantities had been consumed, so that possibly these symptoms were due to gastric catarrh. He had classified the symptoms in 91 cases, and had found that pain and tingling in the feet and the calves of the legs were a prominent and fairly constant symptoms.

Dr. F. W. TUNNICLIFFE, whilst agreeing that arsenic in the beer accounted for the chief symptoms, thought its action might have been modified by the presence of selenium, which he had found in sulphuric acid, glucose, and beer.

Dr. FREDERICK TAYLOR could not quite agree that peripheral neuritis with marked tenderness of the calves of the legs was practically limited to cases of alcoholic or arsenical poisoning or to beri beri. He had observed it after typhoid fever and diphtheria and in other conditions.

Dr. SYDNEY RINGER thought that the general action of arsenic was akin to that of the potassium salts, which affected the muscles both of the skeleton and of the heart.

Sir DYCE DUCKWORTH said that in his experience the therapeutic use of even large doses of arsenic was practically free from serious consequences as in the cases before the meeting.

Dr. REYNOLDS, in reply, said that some difficulty of separating cases of peripheral neuritis into etiological groups was caused by the fact that many spirit-drinkers took large quantities of beer.

MEDICAL SOCIETY OF LONDON.

Exhibition of Cases.

A CLINICAL meeting of this society was held on Feb. 11th, Mr. J. H. MORGAN, the President, being in the chair.

Dr. C. E. BEEVOR showed two cases of Paralysis of the Serratus Magnus and the Lower Half of the Trapezius occurring in joiners (occupation paralysis). The two cases were identical. One man, aged 27 years, had severe pain in August last in the right supra-spinous fossa; two months after he noticed difficulty in raising the arm and two weeks later the deformity of the scapula was observed. The other patient, a man, aged 18 years, had severe pain behind the right shoulder-blade and along the axilla; two weeks after he was unable to raise the arm above the horizontal line and a month later it was observed that he had complete loss of power of the right serratus magnus and of the lower half of the trapezius. In both cases there was inability to advance the arm and carry it upwards beyond the horizontal line, and in this attempt the scapula was drawn upwards and its posterior border projected backwards owing to the serratus magnus being absent. The wasting of the trapezius below the level of a horizontal line from the second dorsal spine to the spine of the scapula was well shown by making the patient carry the arm horizontally backwards against resistance. It was pointed out that "winging" of the scapula might be produced by absence of the serratus or of the lower fibres of the trapezius; in the former the deformity increased as the arm was advanced to the horizontal position, beyond which the patient could not raise it, while in paralysis of the trapezius without the serratus the deformity increased till the arm reached the horizontal line, but above this point the arm could be raised and the deformity disappeared. In the present cases both muscles were affected, but in the first case the serratus had partially recovered and the deformity diminished after the arm passed the horizontal line. The affected muscles gave no reaction with the faradaic current and only a slight slow reaction with the constant current. There was no anæsthesia. Both patients were joiners and the muscles affected were those of the right arm, which would be most used in planing. It seemed probable that the lesion was a neuritis affecting the intra-muscular motor and sensory nerves and that the character of the work was a determining cause and the cases might be looked upon as those of occupation paralysis. In both cases only the fibres of the trapezius below the level of the second dorsal spine were affected and in several other cases Dr. Beevor had found that this was the level of the lower border of the unaffected fibres, where the lower half of the trapezius was paralysed. The reason of this might be due either to the distance of the lowest end of the spinal accessory nerve from its trophic centre in the cervical cord or to the part of the muscle which escaped being the fibres which are supplied by the third and fourth cervical roots as well as by the spinal accessory nerve.—Mr. A. E. BARKER and Mr. EDMUND OWEN discussed the case.

Mr. F. C. WALLIS showed a young woman who had Congenital Synostosis of the Upper Ends of Both Radii and Ulnæ and on one side Ischæmic Paralysis (Volkmann) which supervened on using Esmarch's band during an operation for the relief of the congenital disability.

Mr. WALLIS also presented a second patient who suffered from Pressure Paralysis the result of Tight Splinting for Backward Displacement of the Upper End of the Ulna. The patient showed atrophy of the muscles of the hand supplied by the ulnar nerve.

Mr. H. BARNARD showed two patients—a boy, aged three years, and a girl, aged four years—with Typical Ischæmic Contraction of the Forearm in each case. The deformity was removed by splitting and elongating the flexor tendons through a longitudinal incision above the wrist and the power of supination was restored by elongating the pronator radii teres and detaching the pronator quadratus from its ulnar attachment.—Mr. WALLIS, in reply, said that in cases where no power had returned in the contracted muscles he doubted whether much

improvement would be obtained by tendon elongation.—Mr. OWEN congratulated Mr. Barnard on the good results which he had obtained.—Mr. WALLIS stated the opinion that in ischæmic paralysis operations should not be undertaken until a fair amount of power had returned in the affected muscles.

Mr. MARMADUKE SHEILD showed a boy in whom after failure of the ordinary means he had Removed a Halfpenny which had Lodged Opposite the Upper Edge of the Sternum. The œsophagus, which at the site of operation was covered with indurated inflammatory tissue and glands, was incised longitudinally and the body grasped with long forceps and removed. From the facts that some force had to be used before it was dislodged and that the escape of some pus followed its removal there was no doubt that the body had caused ulceration. The wound was left open and closed slowly in spite of the septic conditions.—The PRESIDENT said that it would be interesting to watch the patient with a view of ascertaining whether the operation was followed by any stenosis of the œsophagus.—Mr. KELLOCK observed that the seat of lodgment of the coin in Mr. Sheild's case was the favourite one and that usually the "coin-catcher" was efficacious.—Mr. WALLIS and Mr. BARKER had also experience of similar cases in which removal was effected by the "coin-catcher."—Mr. SHEILD, in reply, said that he had removed coins, and also a tooth-plate, withh the "coin-catcher," and in this case he had tried the same means but without avail.

Mr. SHEILD also showed a woman after Anterior Gastro-enterostomy for Pyloric Obstruction. The pylorus was found to be thickened and knobby. Murphy's button was used to effect the anastomosis. The patient made a rapid recovery and had put on two stones in weight when she left the hospital.

Mr. SHEILD also showed a man on whom he had operated for a large intermuscular tuberculous abscess of the thigh. An incision 24 inches long was made and the large cavity was allowed to heal by granulation.

Mr. STANLEY BOYD showed a man, aged 47 years, who eight or nine years ago had Severe Pain in the Chest and Abdomen after Food. Vomiting began six years ago in attacks lasting from one to three weeks, with intervals of from four to six weeks, and had continued up to admission. Vomiting usually occurred after lying down at night; about three pints of frothy matter were usually brought up. There was no hæmatemesis but much flatulence. The stomach usually felt distended. Vomiting relieved the distension and pain. He was admitted on December, 1900, under the care of Dr. Abercrombie after a month of daily vomiting. He was transferred to Mr. Boyd's care on Dec. 27th. Even after a fortnight's rest and treatment, which arrested the vomiting, the patient was very thin, pale, and feeble. Abdomen: stomach formed a visible tumour in the left hypochondriac and lumbar, the epigastric, and umbilical regions. No tumour or hard mass could be felt. Splashing was obtained. Capacity was nearly two quarts. There was no sarcinæ in the contents. On Dec. 29th posterior gastro-enterostomy was performed. The opening was from one and a half to two inches long between the stomach and first loop of jejunum, and the edges were secured by three continuous lines of fine silk suture on either side of it. The most external held the sero-muscular coats, the second the cut edges of the same coats, and the innermost united the edges of the cut mucosæ. With regard to the after course the patient vomited once only. Peptonised milk was given by the mouth soon after and was continued in increasing quantity. Nutrient enemata were also given for two days. Minced meat-and-bread were given on Jan. 5th, and the quantity was quickly increased, the appetite being hearty. The wound healed perfectly. The temperature was 100° F. on the second evening, 101° on the 3rd and 4th, and then practically normal. As to the patient's weight, nine days before operation it was 7 st. 12 lb.; 12 days after the operation it was 7 st. 7 lb.; 26 days after operation it was 8 st. 7 lb.; and 40 days after operation it was 9 st. 2 lb.—The PRESIDENT had operated both by the anterior method—i.e., by bringing the small intestine up in front of the colon to the anterior surface of the stomach and using a button—and by the posterior method—i.e., by bringing up the small intestine through an opening made in the transverse meso-colon and making a communication with the posterior aspect of the stomach by means of stitches.—Mr. BARKER said that rapid improvement after gastro-enterostomy could not be taken to mean that the case was not one of cancer. For some years past he had adopted the posterior operation and it had not proved to be much more difficult than the anterior method. With practice the operation could be done with suturing almost as rapidly as with Murphy's button.—Mr. WALLIS said that in some cases the patient did better if placed in the sitting position after operation.—Mr. OWEN had found it advantageous to turn the patient face downwards after meals when the anterior operation had been used.—Mr. SHEILD stated that he allowed patients to lie in the position they found most comfortable.

Dr. W. HUNTER showed a case of Pernicious Anæmia. The patient was a man, aged 37 years, who had enjoyed good health till two years ago when pallor (lemon colour), with pain in the mouth and stomach came on; an inflammatory condition of the tongue was present and was relieved by the removal of three very bad teeth. The gastric pains and anæmia increased, so that he became extremely anæmic, with urobilinuria. The blood corpuscles were 27 per cent. and hæmoglobin 35 per cent. of normal. Suppuration of the gums, which had been present for five years, continued. The treatment consisted of oral and intestinal antisepsis with injections of antistreptococcic serum. In six weeks he steadily improved and gained 7 lb. in weight. Liquor arsenicalis was then added to the treatment and five weeks later he had gained an additional stone in weight and was discharged as cured.—Dr. J. F. H. BROADBENT referred to two cases in which the symptoms of pernicious anæmia had been closely simulated by anæmia secondary to other causes. The first was a case of septic anæmia and was successfully treated by injections of cacodylate of soda, and the second was a case of contracted kidney in which there had been no clinical evidence of the condition.

Dr. STCLAIR THOMSON exhibited two cases to show the desirability in certain cases of Removing the Tonsils by Enucleation. The first patient was a woman, aged 38 years. In 1894 she was in close attendance on her husband who was very ill with tonsillitis and a foul discharge from his throat. Soon after she noticed in her tonsils cheesy collections of offensive taste and fœtid odour. The local conditions were very similar to those presented by her son who was the second case shown at the same time. For this condition she was under continuous treatment for three years. During two years she attended Dr. Thomson's clinic and was actively treated with gargles, paints, lozenges, caustics, the galvano-cautery, and incisions laying open the tonsillar crypts. At the same time attention was given to her digestion and general health. She remained unrelieved. Accordingly, two years ago the imbedded tonsillar stumps were enucleated under chloroform and she had since been quite free of the chronic fœtid follicular tonsillitis which had been such a persistent nuisance. There had been some regeneration of lymphoid tissue between the pillars of the fauces, but there were no crypts in which these cheesy septic concretions could form. The patient found that her voice had not in any way been injured, but rather improved, for singing. The second patient was the son of the former one. He was a boy, aged 10½ years. When four years old his tonsils were noticed to be enlarged and they were removed at the Throat Hospital. He was not again troubled with them until after scarlet fever, at the age of six years, when they were again enlarged and were removed with the guillotine at the Throat Hospital by Dr. StClair Thomson. A few months later cheesy collections were noticed in the crypts of the tonsils, and these had since continued almost without intermission. He was under treatment from September to December last. The chief complaint was of his foul breath, which was said to be most marked in the morning, but was perceptible when he was asleep with his mouth closed. The tonsil stumps were seen to be deeply imbedded between the faucial pillars. They were riddled with crypts, some of which were half an inch deep. From these crypts dirty white, fœtid, cheesy matters were easily extruded. There were no adenoids. It was seen that it was impossible to thread these tonsillar stumps into the ring of the guillotine. In the previous case all attempts to obliterate the crypts failed. The choice of treatment, therefore, seemed to lie between punching out the remains of the tonsil by *morcellement* or enucleation, as in the former case. The mother of the boy was so gratified with the result in her own case that she was anxious for him to have the same treatment. The operation was performed under a general anæsthetic, chiefly by a pair of curved scissors and the fingers.

Dr. J. L. BUNCH showed a case of Localised Abdominal Swelling. The patient was a child, aged three years, who

was strong and healthy up to five months ago, when she had bronchitis and was in consequence kept in bed for a fortnight. When she got about again she seemed rather weak and ailing at first. Soon afterwards her mother noticed a swelling of the right side of the abdomen, and during the last three months this had gradually increased in size. The swelling was said never to become appreciably smaller, but the mother thought that it was sometimes a little "softer" first thing in the morning or after the child had been lying down for a considerable time. The child had never been out of England. There was now an elastic swelling of about the size of a cricket ball in the right hypochondriac and upper part of the right lumbar regions, which formed a definite prominence when the child stood up. The percussion note over the swelling varied. No thrill could be made out. The child was apparently in good health. The urine was normal. —The PRESIDENT thought that the swelling was due to a local weakness of muscle rather than to a definite tumour.—Dr. EDMUND CAUTLEY had under his care a similar case and regarded it as being due to muscular defect.

CLINICAL SOCIETY OF LONDON.

Address of Condolence to His Majesty King Edward VII.—Leucocythæmia.—Instantaneous Radiography.

A MEETING of this society was held on Feb. 8th, Sir R. DOUGLAS POWELL, Bart., the President, being in the chair.

The proceedings opened with an address of condolence to His Majesty King Edward VII. in respect of the death of Her Majesty the late Queen and of congratulation on his accession to the throne.

Dr. D. N. NABARRO read notes of a case of Pronounced Spleno-myelogenic Leucocythæmia subsequent to an attack of Malarial Fever. The patient, a man, aged 23 years, consulted Dr. Thin on account of enlarged spleen on March 28th, 1900, at the recommendation of Dr. C. H. Perram of Bedford. He went to Vancouver in 1899 and considered himself to be then in good health. During April and May of that year, which were wet and cold months, he felt very tired. In July he was attacked by "chills." The rigors came on about midday, lasting an hour, then for an hour he felt hot in the head, with a final stage of perspiration. He was confined to bed for four days. Not regaining his strength he returned to England in October of the same year. He had noticed that he was getting corpulent towards the end of August and thought he was getting fat. The abdominal enlargement, however, was found to be due to enlarged spleen when the patient was first examined by Dr. Perram on Dec. 13th. Dr. Thin wrote to Mr. J. A. Pybus for further information regarding the origin of the illness, and was informed by him that the patient first consulted him on July 5th, 1899, and he was asked to see him again on July 11th. He then complained of feeling ill, had a quick pulse and a furred tongue, with a temperature of 104° F. Under treatment, antipyretics and quinine, the temperature sank to 99·5°, and on July 26th he was considered cured. During August and September he was subject to sensations of chilliness but had no rise of temperature. When he left for home on Sept. 26th he seemed to Mr. Pybus to be suffering from some "pernicious toxæmia." He told Mr. Pybus that while at Manitoba, about April 2nd, he stayed two days in a low, swampy place, and from July 20th to 27th he camped beside a small creek where there were swarms of mosquitoes. Mr. Pybus informed Dr. Thin that he saw three other cases of fever in a house two miles distant from that in which the patient under notice lived. These cases were similar in nature and were characterised by high temperature, 104° in one case and 106° in a second. The attack in these cases lasted 10, 16, and 20 days respectively, and all the patients made good recoveries. Mr. Pybus stated that "these were the only cases of fever in the district during the 10 years he had been in practice there and were believed to be of a typho-malarial character." On Dec. 13th the spleen was found definitely to be the cause of the abdominal enlargement. On March 28th, 1900, Dr. Thin found the patient to be very pale and anæmic and with a "very large spleen, which descended to the groin on the left side and crossed nearly to the ilium on the right side." No malarial parasites or pigmented leucocytes were discovered on careful examination, but the white corpuscles were greatly increased in number. On May 25th, by the kindness of Dr. Thin, the patient was seen by Dr. Nabarro and a complete blood examination was made. The spleen was then as large as it had been found to be in March and was slightly tender about the notch. There was no enlargement of the liver or of any lymphatic glands. In September another differential count of the leucocytes was made and on Nov. 16th the patient was again seen at Dr. Thin's house and a complete blood examination was again made. (The conditions that were found at the different examinations are shown in the subjoined table.)

—	1900.			
	March.	May 23rd.	Sept. 8th.	Nov. 16th.
Red corpuscles	—	3,250,000	—	2,966,700
White ,, ...	—	750,000	—	666,700
Ratio of white to red	—	1 : 4½	—	1 : 4½
Hæmoglobin per cent.	—	36–40	—	40–42
Colour index	—	6	—	0·68
Lymphocytes (small)	9 per cent.	6	1·5	2·3
,, (large)...	10 6	4	2·0	0·5
Polymorphonuclear-leucocytes	41	47	38	38·4
Eosinophiles	10	8	8·6	10·8
Myelocytes	28	32·5	46·5	42
Basophile	1	2·5	0·8	Very few.
Nucleated red (per 1000 white counted)	13	51	10	20

Many transitional forms between large lymphocytes, polymorphonuclear leucocytes, and myelocytes were seen. The films were fixed by immersion in alcohol and ether and stained by eosin and hæmatoxylin and by the Ehrlich-Biondi triple stain. In November the patient was feeling so much better that he was desirous of taking up some occupation. The spleen was as large as ever but causing no inconvenience beyond a feeling of weight when the patient was tired. Treatment had brought about but little benefit as regards the condition of the blood or of the spleen. The patient had had at various times arsenic, iron, quinine, and preparations of hæmoglobin and bone marrow. There were a few interesting points in the case—(1) the antecedent history of malaria, almost certainly indicated by the "chills" described; (2) the great size of the spleen before attention was drawn to it and the slight inconvenience caused by it; (3) the condition of the blood showed a great diminution in the percentage of lymphocytes (from 20 to 23 per cent.) and a corresponding increase in the number of myelocytes (from 28 to 42 per cent.) between March and November, 1900; and (4) in spite of the marked anæmia and the large number of white cells in the blood the patient was apparently in good general health and was anxious and able to follow an occupation.

Mr. E. W. SHENTON displayed a large number of radiograms taken with very short exposures, examples of so-called Instantaneous Radiography. He explained that the word "instantaneous" merely conveyed the idea that the exposure had been reduced to reasonable limits—i.e., from a fraction of a second to a maximum of 30 seconds. This he had been enabled to accomplish by the aid of x ray tubes of larger size, whereby not only was the exposure materially reduced, but the deeper parts of the body could be readily seen on a screen. He described the advantages of these tubes in the detection of renal calculus, in the treatment of fracture, and in the rapid localisation and extraction of foreign bodies. Mr. Shenton then demonstrated a very simple and effective method of ascertaining the exact position of a foreign object inside the body. When the shadows of the body and foreign object were thrown upon the screen, on the tube being moved from side to side it was seen that the rate of movement of the two was different owing to their different distance from the tube. If a probe were placed behind the screen at a distance at which its movements approximated those of the foreign body, that would be the distance of the latter, and by repeating this proceeding in different positions the whereabouts of the foreign body could be ascertained to a nicety. (This was demonstrated by the aid of a lime-light projection in a perfectly satisfactory manner.)—The PRESIDENT said that although Mr. Shenton had not

touched upon cases of mediastinal growth or other internal disease, the subject was one which could not fail to interest physicians as well as surgeons.—Dr. G. B. BATTEN said that he had used the rays very much in his practice and had never seen as complete an installation as that of Mr. Shenton or any results approaching his in clearness and rapidity of exposure. He himself had used identical apparatus but had not obtained identical results. With the tubes used by Mr. Shenton things could be seen on the screen which would escape notice under other circumstances. They were not, he said, what would be called high vacuum tubes, but gave an abundance of x-rays. He thought that Mr. Shenton had not done himself justice in that he had not described the details of his method, it being the details which enabled him to obtain such admirable results. With regard to the localisation of foreign bodies he related a case in which a young man had lodged a bullet in his thigh. After some search it was made out near the knee, and by marking the spots on the knee at which it was seen in different positions they obtained an indication of locality which enabled the surgeon to remove it almost at once.—Mr. STANLEY BOYD asked what was the peculiarity of the method which enabled it to yield such excellent results?—Dr. HUGH WALSHAM raised the question whether such short exposures were desirable in cases of pulmonary tuberculosis. He had failed to obtain a shadow in a case of moderate severity which came out with a longer exposure, though he admitted the manipulator might go too far in this direction. He thought, too, that photographs sometimes revealed appearances which would not be seen on the screen.—Mr. CAMPBELL WILLIAMS asked whether dermatitis had ever resulted from these exposures, and he mentioned two cases in which more or less severe inflammation of the dermis had been caused by prolonged exposure.—Dr. EASTES asked whether the retinæ were affected by constant exposure to the rays?—Mr. SHENTON, in reply, said that there was a good deal to be done on the medical side. This was a branch at which they were all working at present but much remained to be learned. He disclaimed any technical knowledge in respect of the manufacture of these tubes and his results were merely empirical. He had found that the large tubes gave better results. Most tubes were made with three electrodes, but he found that two sufficed to obtain these results. He pointed out that for each case there was a correct exposure and any error either way marred the results. He thought photographs should be used to confirm what they had seen on the screen. Some things, however, were better seen in photographs owing to the fact that screens were made of coarse material so that fine details might be overlooked. He had seen nothing of dermatitis except what he got on his own hands. He had no knowledge of any effect on the retina.

OBSTETRICAL SOCIETY OF LONDON.

Exhibition of Specimens.—List of Officers and Council.—Annual Address.

A MEETING of this society was held at 20, Hanover-square, W., on Feb. 6th, Mr. ALBAN DORAN, the President, being in the chair.

The following vote of condolence to the Royal Family was passed by the Fellows:—

That the President and Fellows of the Obstetrical Society of London humbly beg to express their sincere sorrow at the death of their beloved Queen and they further beg to tender to the Royal Family their deepest sympathy and to His Majesty the King the assurance of their loyalty and devotion to the throne.

Mr. HASTINGS GILFORD showed a specimen of Rupture of the Sac of an Early Primary Ovarian Gestation in a woman, aged 38 years. Rupture with severe internal hæmorrhage occurred 14 days after the previous menstrual period. At the operation the Fallopian tubes were found to be intact and there was a rent in the left ovary, with thin irregular edges, with firm clot attached. About two pints of blood had escaped from the rent. The firm clot attached to the rent was believed to be a "blood-mole." Mr. Gilford argued against the hæmorrhage having come from either a tubal abortion or a ruptured matured Graafian follicle.—Dr. T. W. EDEN said that, speaking from a casual examination of the specimen, he doubted if it were really an example of ovarian pregnancy. On naked-eye examination the so-called mole did not show much evidence of being a product of gestation at all, but perhaps the presence of chorionic villi had been demonstrated by the microscope. The specimen differed greatly from the examples of ovarian gestation recently shown to the society by Dr. E. O. Croft and from the classical case of van Tussenbroek in the circumstance that the ovary was little altered in its outline and shape, the cavity in which "the mole" was contained being quite superficial. One of the essential points in the diagnosis of ovarian pregnancy was the demonstration of ovarian tissue in the wall of the gestation sac, and this did not seem to be practicable in the case now before the society, for the wall of the sac appeared to be an adventitious product.—Dr. C. J. CULLINGWORTH, speaking in reference to the condition of the Fallopian tube, said that too much importance should not be attached to this. It had been shown that the tube might very quickly resume its normal size and appearance after tubal rupture, and it was obvious that it would even more readily do so after tubal abortion. He referred to cases reported by himself, the President, and Mr. Bland-Sutton, to prove that the empty condition and innocent appearance of the tube were not incompatible with the gestation having been primarily tubal.—Dr. HEYWOOD SMITH asked if ovarian pregnancy had been observed in the lower animals.—Mr. GILFORD replied and consented to his specimen being referred to a sub-committee for report.

A report of the sub-committee on Dr. Croft's specimen of Primary Ovarian Pregnancy was read, agreeing with his view of the case.

Dr. W. H. TATE showed a Fibroid Tumour with marked cystic degeneration, removed from a patient, aged 63 years, in whom both ovaries had been removed 11 years previously. The woman suffered from severe menorrhagia due to a fibroid which reached up to the umbilicus. After the operation in 1889, when a tubo-ovarian cyst on the right side and the appendages on the left were removed by Dr. Cullingworth, she remained well till 1896, when hypogastric pain recurred and the fibroid was found to be increasing in size. Last month the fibroid had reached 11¾ inches from the pubes and was evidently cystic. Dr. Tate removed the fibroid by abdominal hysterectomy, and the patient recovered. The tumour was found to be a fibroid converted into a loculated cavity containing 42 ounces of coagulable straw-coloured fluid. The case proved that degenerative changes in uterine fibroids might occur after complete removal of the appendages as well as after a natural menopause.—Dr. CULLINGWORTH urged the importance of recording all cases bearing on the liability of fibroids to increase in size and to undergo serious degenerative changes after the menopause.—After remarks by Dr. A. H. N. LEWERS and Dr. HERBERT SPENCER, Dr. C. HUBERT ROBERTS asked if the spaces in the specimen had an endothelial lining. He had not found such a lining in any cystic fibroids of the uterine body, but the spaces contained an easily coagulable serous fluid. He thought that such spaces were due to retrograde degeneration and were not of lymphatic origin. The spaces found in cystic fibroids of the cervix were not uncommonly lined by epithelium.—Dr. TATE replied.

Mr. HUGHES R. DAVIES showed Pessaries for use in cases of prolapsed and retroverted uteri.

The report of the honorary treasurer, Dr. J. Watt Black, was then adopted upon the motion of Dr. C. H. F. ROUTH, seconded by Dr. PETER HORROCKS.

The report of the honorary librarian, Dr. M. Handfield-Jones, was adopted upon the motion of Dr. A. H. N. LEWERS, seconded by Dr. DRUMMOND ROBINSON.

The report of the chairman of the Board of Midwives, Dr. Percy Boulton, was adopted on the motion of Dr. G. E. HERMAN and Dr. C. J. CULLINGWORTH.

The following List of Officers and Council for the ensuing session was then announced, Dr. EDWARD MALINS proposing, and Dr. W. G. GOW seconding, a vote of thanks to the retiring Vice-President and members of council:—President: Dr. Peter Horrocks. Vice-Presidents: Dr. John W. Byers (Belfast), Dr. William Radford Dakin, Dr. John Phillips, and Dr. Edward Malins (Birmingham). Treasurer: Dr. James Watt Black. Chairman of the Board for the Examination of Midwives: Dr. W. R. Dakin. Honorary Secretaries: Dr. Herbert R. Spencer and Dr. Amand Routh. Honorary Librarian: Dr. Montagu Handfield-Jones. Other Members of Council: Mr. Charles Edmund Adams, Dr. A. H. Freeland Barbour (Edinburgh), Dr. George Francis Blacker, Dr. Robert Boxall, Dr. Henry Briggs (Liverpool), Dr. Francis Henry Champneys, Dr. Thomas Vincent

Dickinson, Dr. Charles Owen Fowler, Dr. William John Gow, Dr. Walter Spencer Anderson Griffith, Dr. George Ernest Herman, Dr. Arthur H. N. Lewers, Dr. Thomas Robert Lombe (Torquay), Dr. William Loudon Reid (Glasgow), Dr. William Japp Sinclair (Manchester), Dr. Arthur Francis Stabb, Mr. John William Taylor (Birmingham), and Dr. Charles Percival White.

The PRESIDENT delivered the Annual Address. He remarked that the society, founded in 1859, was within eight years of its jubilee and never stood higher than it did at present for the high quality of the contributions read at its meetings and for the interest taken in its discussions. After reviewing the work of the past year, the President announced that the council had appointed a sub-committee to draw up an "index" founded upon the various systems of teratological nomenclature at present in use and upon the specimens in the London museums, for it was felt that an index of this kind would be of great value to Fellows showing specimens before the society and might well become a standard system of nomenclature, at least for English writers. The President read obituary notices of the five Fellows of the society who had died in 1900—namely, one honorary (and original) Fellow, Sir W. O. Priestley, and four ordinary Fellows, Dr. W. Chapman Grigg, Mr. Claude Clarke Claremont, Dr. Horace Howell, and Dr. John Baptiste Potter. Finally, the President, in resigning his office, thanked the society for the friendly support which they had granted him and congratulated them on their choice of a successor.—A vote of thanks to the retiring President for his address and for his able chairmanship was moved by Dr. F. H. CHAMPNEYS, and seconded by Dr. J. WATT BLACK, and was carried by acclamation.—The PRESIDENT replied.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

Hospital Isolation in Scarlet Fever.

A MEETING of this society was held on Feb. 8th, Dr. J. C. MCVAIL, the President, being in the chair.

Dr. C. K. MILLARD, medical officer of health of Burton-on-Trent, read a paper on the Influence of Hospital Isolation in Scarlet Fever. The influence of hospital isolation on the spread of epidemic and infectious diseases could not, he maintained, be considered as a whole; each disease must be studied separately, for it did not follow from the success attending such measures with small-pox or cholera that they were equally applicable to scarlet fever or measles. After quoting the opinions expressed by the late Sir George Buchanan and Dr. A. Newsholme that such statistics as those with which they had at present to be content were not conclusive in favour of the influence of these hospitals in reducing the prevalence or the fatality of scarlet fever, and that they must wait for further experience with the better recognition of factors as yet ill understood or undiscovered, he pointed to the admission of Dr. Wilson of Ayr that the decrease in the mortality from scarlet fever of late years, though coinciding in point of time with the adoption of notification, could not be wholly due to these measures, since it had been likewise observed in towns where no provision had been made for isolation, in rural districts without sanitation, and in the United States of America, where isolation was unknown. He quoted also the opinion advanced by Mr. E. D. Marriott of Nottingham that isolation or, as he described them, aggregation hospitals actually contributed to the diffusion and increased virulence of the infection, He then proceeded to give an account of his own inquiries. He had obtained from 113 towns—viz, 31 great towns, 81 smaller towns, and the County of London—returns of the population, cases notified, cases under five years of age, cases isolated, and deaths registered, as well as the personal opinions of the medical officers of health as to the value of isolation in reducing either the mortality, the prevalence, or the fatality. The majority of these were favourable, but apparently mere personal impressions not based on strict inquiry. Anticipating objections, he maintained that all the requisite conditions of a scientific experiment were present; the disturbing influence of epidemics and local circumstances could be eliminated by grouping towns and taking series of years; and they had control experiments in towns that had never attempted isolation at all. The contrast between the fearful mortality from scarlet fever prior to the years 1875–80 and the insignificant death-rate and fatality irrespective of the prevalence in subsequent years had been ascribed to influence of isolation hospitals, the adoption of which coincided with "the great slump," but, as his diagrams showed, it occurred in a large proportion of these towns before the erection of the hospitals had been begun, and was equally pronounced where there had never been any such hospitals. He had based all his calculations on the total populations or in single towns on the actual number of cases, since he could not obtain the preferable basis of the number of persons under 10 or 15 years of age. In Huddersfield with the lowest general death-rate and the lowest infant mortality of any of the 33 great towns, with notification and isolation carried out for over 20 years, and the cases treated in hospital rising from 67·7 per cent. in 1880–89 to 90·4 per cent. in 1890–99; the average annual number of cases had risen from 256 in the former to 427 in the latter, the mean attack rate having been 4·31 per 1000 and the fatality 4·49 per cent, as against 4·45 and 3·29 in a group of four large towns without any isolation. The lower fatality of hospital cases was often urged in favour of those institutions, but in Huddersfield the difference was so great—viz., 3·18 per cent. for hospital cases and 16·91 for home ones in 1890–99, or in the last two years 1·8 and 1·5 against 18·2 and 28·5—that it could not be wholly due to the treatment. He criticised in like manner the statistics of other large towns in order with like results, the apparent reduction at Derby being explicable by the actually decreasing birth-rate in an increasing population. At Oldham, in consequence of small-pox in 1892, the hospital was closed to scarlet fever for two years, yet during those years and that following there was less fever in the town than ever. Swansea, on the other hand, a town the sanitary conditions of which were none of the best, and where prior to 1880 the mortality in successive epidemics had been frightful, had, without an isolation hospital, shared in the general improvement, the attack rate for 1891–99 having been 5·74 per 1000, and the fatality in 1895–99 only 2·19 per cent., and in 1896 three deaths in 549 cases. Equally negative results were shown by the statistics of greater and lesser towns when grouped as those in which over 40 per cent., under 40 per cent., and none or practically none of the cases were isolated in hospitals, and whether the periods taken were 18 or 10 years, and again when the Lancashire towns, excluding Manchester, Salford, and Liverpool, were compared. They were, he considered, driven to the conclusion that the aggregation of cases in hospitals, under the name of isolation, developed a type of fever of greater persistence and infectivity, of which the "return cases" were the product, and which would in course of time be felt in a generally increased virulence of scarlet fever throughout the land, nor had he any trust in convalescent hospitals as a means of avoiding the danger. A full and authoritative inquiry was needed.

Dr. WILSON (Ayr) considered that no decisive evidence had been as yet adduced of the beneficial influence of hospital isolation, and Sir Richard Thorne, in the Majority Report of the Vaccination Commission, admitted this when he ascribed the reduced mortality from scarlet fever to a recent change of type, and suggested that the advantages of hospital treatment might have been over-estimated, even in the case of such diseases as small-pox and cholera. The diversity of opinion among experts indicated the need for inquiry with a view, not to the abandonment, but to reforms in their administration—a matter of great difficulty. Return cases occurred as often in private as in hospital practice, and in the latter the symptoms often did not develop until after the patient had left the hospital.

Mr. SHIRLEY MURPHY maintained that the real question, what the mortality would have been in the absence of the hospital, could not be solved by such statistical methods. Inquiry was needed, but the collection and collation of mere opinions by a Royal Commission would be useless. It must be the individual observation year after year of the cyclical and seasonal prevalence of the disease as well as of casual outbreaks, for there were many causes of prevalence and means of infection known and unknown, and the provision of hospitals could not be expected to alter the laws of natural phenomena. The words of Sir George Buchanan as to their ignorance of these, even the obvious connexion between season and disease, were and would long be as true as when uttered. But personal contact was a cause of the spread of the disease, and if isolation could not be secured at home it must be provided in hospital.

Dr. P. BOOBBYER (Nottingham) would be the last to defend the present management of fever hospitals, which were everywhere overcrowded—grossly so at Nottingham; yet in 1899 they had only 16 deaths in 1200 cases, and no increase in the mortality outside, which was also the lowest on record. There was absolutely no evidence forthcoming of the evolution of a new type of infection in hospitals, and the equivalents of return cases were at least as frequent in private practice, though often unnoticed.

Dr. A. NEWSHOLME (Brighton) considered Dr. Millard's statistics for each year most valuable, but averages for groups of towns were of no practical use, for not only might the circumstances, known and unknown, of the several towns differ, but the recurrent maxima of prevalence, the meaning of which was a great desideratum, falling in different years were thereby deprived of all significance. Personal infection was, at any rate, one cause, and with the isolation they had one cause less. If the mortality in America had sunk without hospital isolation it must be owing to some unrecognised factor common to both continents and was no argument against the adoption of another means in addition. Home cases frequently spread the infection after the most complete disinfection possible.

Mr. B. BROWNING (Weymouth) remarked that home isolation was perfunctory, whereas isolation in hospital was real, though too often combined with overcrowding. In his town they had had 127 cases in a single outbreak, nearly all sent to the hospital, but no return cases whatever. The cause was found to be the milk-supply from three infected dairies outside the district.

Mr. T. ROBINSON (Leicester) maintained that Dr. Millard's method of grouping effaced sanitary conditions, which were evidently powerful factors. Why but for such conditions had Bolton and Oldham with equal isolation such different mortalities, and Wigan and Warrington like mortalities with such different proportions of isolated cases?

After remarks by Dr. W. A. BOND (Holborn), Dr. E. GWYNN (Hampstead), Dr. C. SANDERS (West Ham), and some others Dr. MILLARD replied, reiterated his arguments, and defended his grouping of towns as tending by obliterating other differences to emphasise the one in question. He, however, would not ask for the suppression of isolation hospitals, but merely for a searching inquiry into, and reform of, their administration and he was ready to let go his speculations as to an intensification of the infection.

LIVERPOOL MEDICAL INSTITUTION.

Resolution expressive of Condolence with His Majesty the King on the Death of Her Majesty the late Queen and of Attachment to the Throne.

THE eighth ordinary meeting of this society was held on Jan. 31st, Mr. EDGAR A. BROWNE, the President, being in the chair. At this meeting, which was very largely attended, the ordinary business was entirely suspended and the members met together to express as individuals and as a body their sorrow at the loss of their beloved Queen and their sympathy with and attachment to the throne. The PRESIDENT, Dr. NEVINS, Sir WILLIAM BANKS, Dr. W. CARTER, Dr. ARTHUR EVANS, Professor A. M. PATERSON, Dr. E. W. HOPE, and Dr. MACFIE CAMPBELL made speeches referring to the example, beauty, and dignity of our dead Queen's life, and commenting upon the unparalleled advances made in all branches of science, and more especially with reference to those made in medicine, surgery, and public health, during the Victorian era. The following expression of sympathy, moved from the chair and adopted in silence, the members all standing, was directed to be forwarded to the King through the honorary secretary.

TO THE KING'S MOST EXCELLENT MAJESTY.

The members of the Liverpool Medical Institution (founded in 1837, the year of the Royal Accession) desire to record their deep sorrow at the death of their beloved Queen, who for more than 60 years has not only ruled this great Empire with justice and moderation, but has invariably shown wise and humane sympathy with the efforts of all classes of intellectual workers in the kingdom.

They desire to offer to Your Majesty their profound sympathy in your bereavement and to assure you of their attachment to your person and throne.

Exhibition of a Case.—The After-history of Cases of Uterine Cancer treated by Vaginal Hysterectomy.

The ninth ordinary meeting was held on Feb. 7th, Dr. MACFIE CAMPBELL being in the chair.

Mr. G. P. NEWBOLT showed a girl, aged 11 years, upon whom he had operated for the relief of deformity caused by the fact that the left leg was two and a quarter inches longer than the right. By removal of one and three-quarter inches of bone from the elongated left femur the two limbs were made nearly equal in length and the deformity was corrected. The case was illustrated by lantern slides.—Dr. W. ALEXANDER and Mr. RUSHTON PARKER discussed the case and Mr. NEWBOLT replied.

Dr. H. BRIGGS read a paper on the After-history of Cases of Uterine Cancer treated by him by Vaginal Hysterectomy. Between March 24th, 1899, and Nov. 7th, 1900, he had operated on 84 patients. Concerning the after-results, it was shown that where recurrence and death occurred in the series death was not later than the end of the fourth year; consequently a period of over four years was apparently a fair time-test as to radical relief. A report within a year on a series of cases was useless. Dr. Briggs for convenience had subdivided his cases into three groups. Group 1, adapted to the time-test of upwards of four years, included the patients operated upon before the end of 1896, 33 in number, less one who died from operation and two who had escaped observation. Of the remaining 30 six (or 20 per cent.) were alive and radically relieved (from four and a half to 10½ years after operation). Group 2, 38 operations during three years (1897, 1898, and 1899), two deaths from operation, leaving 36 patients, of whom 16 were living and known to be free from recurrence (from one and a quarter to three and five-sixths years' interval) and two living with known recurrence. Group 3, the cases of 1900, referred to 13 patients whose after-histories were too recent to be of any service; one patient died—the result of operation. Most attention was devoted to Group 1. The cases were described and the occasion became the equivalent of an audit, as evidence of the character of the uterine growth was produced. The evidence was (1) a microscopical section for the histological structure; (2) a recent water-colour drawing of the growth *in situ;* and (3) the preserved specimen of the uterus. This threefold evidence was complete in four instances and in the other two the absence of the preserved specimen was compensated for by the excellence of the artists' reproduction. In none was the evidence of the microscopical structure wanting. The proof of radical relief in six cases was apparently established. Referring to Group 2 Dr. Briggs explained that his object was chiefly to show the high ratio of early recurrence. Out of the 71 patients operated upon prior to the end of 1899 three died from operation, 19 had recurrence and died within the first year, and 15 had recurrence and died within the second year. No other causes of death were certified. This ratio of early recurrence was to be deplored; it was often noticed in published records, but putting Group 1 and Group 2 together there were 22 patients out of 66 who had been traced alive and apparently free from recurrence from one and a quarter years to 10 years after operation. In taking the causes of early recurrence into consideration Dr. Briggs said that they were the same as the causes of incomplete operation—delay in diagnosis, the difficulty in ascertaining the limits of the growth, faulty methods of operation, and restricted limits of operation. Each of these causes was alluded to and reference was made to the recent revival of the abdominal route for operation. A summary was given of the morbid anatomy of the 84 growths examined after operation; three were sarcomata, 15 of the 66 carcinomata were malignant adenomata (after Ziegler), and these last-named growths were especially apt to be confused with chronic glandular hyperplasia and simple adenoma by microscopical methods where the clinical signs and symptoms left a doubt. In the body of the uterus malignant adenoma was diagnosed often under difficulties of access to the growth and of structural differentiation under the microscope; the naked-eye features of curetting should be noted. Probably the fashion of prescribing medicinal styptics was in the absence of a diagnosis to be deprecated: it misled patients in many instances into believing that the medical attendant really thought that medicine might cure them of their ailments. The four deaths in the series of 84 cases were: one from shock (30 hours), two from peritonitis (on the sixth and eighth days), and one from embolic septic pneumonia on the thirty-fifth day. They all occurred amongst the more advanced cases of cancer.—Dr. E. T. DAVIES remarked that out of Dr. Briggs's 84 cases there was a primary mortality of 5 per cent. which should not be ignored; that out of 14 cases of cancer of the uterine body which Cullen said was three times less malignant than cancer of the cervix there was a mortality of 50 per cent.

from recurrence, in periods of from six months to three years; and that the seven cases "still living" had only been operated upon at periods from 18 months to five years, which periods Dr. Davies considered too short to speak favourably on these patients. Referring to the tables which included 49 cases of carcinoma of the cervix (the most malignant site of all), 33 patients, equivalent to 67·3 per cent., died in from one to three years, leaving only 16 patients living for periods of from six months to six years, and these periods he considered too short to prognosticate from except in an unfavourable direction. Dr. Davies considered that the surgery of cancer was exactly in the same position as it was when he left it five years ago—a hopeless chaos.—Dr. T. B. GRIMSDALE said that the success measured by radical cure was not great, but there was a distinct gain in the average length of life after vaginal hysterectomy; moreover, the life of the patient was made more bearable—there was the removal of the bleeding and offensive discharge of cervical cancer and of the pain in body cancer. The small mortality of the operation encouraged operators to perform vaginal hysterectomy as a palliative measure, and this, of course, would make the results as far as cure was concerned appear even worse than they should.—Dr. J. E. GEMMELL considered that Dr. Briggs's paper and analysis of cases with the complete record as to pathological condition and after-history comprised not only a valuable record, but were a distinct encouragement to the treatment by vaginal hysterectomy within such limits of selection as fairly free mobility downwards of the uterus, or even (as a palliative measure and freeing the patient from much after-misery and distress) when there were some slight infiltration and thickening of the broad ligaments. The great difficulty was that patients did not seek advice early enough and the bulk of the cases when first seen were inoperable. Dr. Gemmell's cases of vaginal hysterectomy only dated back three years and therefore were without the time-test of four years, but up to the present time he had had no deaths from the operation and several of the earlier cases had, in his opinion, amply justified this method of treatment.—Dr. ALEXANDER also spoke and Dr. BRIGGS replied.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Hæmatemesis.

THE fifth ordinary meeting of this society was held on Feb. 6th, Dr. A. G. MILLER, the President, being in the chair.

The evening was devoted to a discussion on Hæmatemesis, which was opened by a paper read by Mr. MAYO ROBSON of Leeds. This paper was published in full in THE LANCET of Feb. 9th, p. 375.

Dr. J. O. AFFLECK, who followed, thought that the results obtained by Mr. Robson should be ascribed not only to his surgical dexterity and aptitude but quite as much to the thought and care which he had given to the cases and to his large clinical experience. There were two points which seemed to him of importance as regards gastric ulcer. 1. Diagnosis.—There was no absolute diagnostic sign though one could get very near to an absolute diagnosis. The pain referable to an ulcer of the stomach was not always reliable either as regards the situation or the chronicity of the ulcer. Sometimes the pain of a gastric ulcer was misleading—e.g., the pain which was often complained of as starting immediately after the ingestion of food and as pointing to an ulcer at the cardiac end of the stomach. This pain might really not be due to the direct irritation by food but might very likely be caused by the movements set up in the stomach by the presence of food in it, or again it might be due to the outpouring of acid secretion. The pain connected with an ulcer of the stomach might also be reflected and might be referred to one or other iliac region. A careful examination of the gastric contents or vomit by chemical means was often of the greatest value to the physician. In chronic ulceration of the stomach they found alterations in the size and shape of the organ—e.g., dilatation, contraction, or hour-glass constriction. The aid to diagnosis caused by the evolution of carbonic acid gas in the stomach had always seemed to Dr. Affleck a questionable proceeding. Some gastric ulcers were very easily ruptured and he knew of one case where this had happened after the patient had taken a cup of coffee. Though he could not recollect a case of rupture as having been recorded due to distension by gas, still it might occur. He had frequently demonstrated the size of the stomach by simply manipulating the skin over the viscus, thus causing the muscular coats of the stomach to contract and so map itself out. It was not every acute or chronic ulcer which bled, but a recurrent hæmorrhage was very characteristic of chronic gastric ulcer. Acute gastric ulcers were characterised by sudden and violent hæmorrhages taking place within a few hours of one another. 2. Treatment.—As regards the treatment of an acute ulcer one must trust to medical aid in the first instance; but the question always was, How much good did medical treatment really avail? Most of the so-called styptics might be used without the slightest benefit. Dr. Affleck had found most benefit to be obtained from the employment of morphia and absolute rest—both mental and physical rest being thus obtained. The generality of acute ulcers got well of themselves, and so one could in most instances allay the mental distress caused by the bleedings by telling the patient or friends that in all likelihood the hæmorrhage would soon cease. Mr. Mayo Robson advocated operative measures after a second hæmorrhage, but Dr. Affleck said that he would like a little more evidence regarding this. He recollected the case of a girl who died from hæmorrhage and the post-mortem examination showed the presence of 20 ulcers in the stomach and several in the duodenum. Many acute bleeding ulcers underwent complete spontaneous cure. The tendency of chronic ulcer was also to heal. They often found that cicatrisation was almost complete but not entirely. These were the cases which seemed to him to call for operation, as nature's efforts to heal these chronic ulcers often caused much suffering to the patient. Rest and treatment in these chronic cases often led to cures which were more apparent than real, as relapses very soon followed as a rule, the ulcer never having been perfectly healed. Surgical intervention then seemed to him to be chiefly indicated in such chronic cases, but in acute ulcers Dr. Affleck had his doubts as to its advisability. Many patients would much rather submit to a merely mitigating treatment than suffer the much more severe method of treatment by operation. Unless the surgeon was one well versed in the symptoms and diagnosis of gastric ulcer he should not be without the help of the physician.

Sir WILLIAM GAIRDNER took part in the discussion and said that he recollected many cases where the patient's life might have been saved by operative measures.

Professor W. S. GREENFIELD said that while not daring to think that Mr. Mayo Robson's statistics were inaccurate, yet it was possible that they might be capable of other interpretation. It would be most desirable that physicians should lay down definite diagnostic rules for gastric ulcer and for defining the positions of such. He thought that in the case of duodenal ulcers the risks to life were so great that operative measures should be adopted, as also in the case of ulcers of or near the pylorus, even within two inches of it. With reference to the treatment of chronic ulcer of the stomach, it was not the custom here to allow such cases to go about; the important point was to keep such patients at absolute rest. Practically he had found the employment of large doses of iron used persistently of very great value in the treatment of such.

Mr. F. M. CAIRD said that the question really resolved itself into what was to be done in the case of bleeding from the stomach. A certain proportion of cases died from hæmorrhage from the urinary bladder. The treatment of such cases, however, was to rest the bladder by putting in a tube. He would do the same with the stomach—give it absolute rest by performing gastro-enterostomy.

Mr. DAVID WALLACE asked, first, whether Mr. Mayo Robson was in favour of operating for chronic gastric ulcer which had resisted treatment and where the patient was running the risk of perforation and hæmorrhage, and in the second place what was the proportion of hæmoglobin and the number of the red blood corpuscles in a case which he would consider beyond remedial measures. He asked if Mr. Robson put any stress on the blood conditions as regards operation.

Dr. ALEXANDER JAMES said that he had never met with any case of hæmatemesis so severe as to require surgical treatment. On looking over the notes of his infirmary cases he found that he had treated 50 cases of gastric ulcer and in 46 of these hæmatemesis was severe (in one such case the red corpuscles had fallen to 450,000 and the hæmoglobin to 6 per cent., and yet the patient recovered perfectly). In the

treatment of such cases deprivation was, he thought, better than refreshment and he had not found any good to result from the use of astringents.

Dr. BYROM BRAMWELL said that at first sight it might be thought that the surgeon tended to interfere rather too much. He hardly thought that modern statistics would bear out what Mr. Mayo Robson had stated. The modern treatment of gastric ulcer was much more beneficial than that formerly employed. He considered rectal feeding and prolonged rest the most potent factors in treatment. Personally, he had never had a case ending fatally as a result of gastric ulcer alone.

Dr. JOSEPH BELL and Dr. CHARLES W. MACGILLIVRAY also spoke.

Mr. MAYO ROBSON, in his reply, stated that he had employed not antiquated statistics but very recent ones. Thus, Rodman (June, 1900) had made a very careful analysis of deaths from gastric ulcer and found that 8 per cent. were due to hæmorrhage from such ulcers. Dreschfeld gave 3½ per cent. and Lebert 3 per cent. The statistics he used had been obtained from a very large number of cases investigated. Taking these all over it might be said that from 3 to 6 per cent. died from hæmorrhage. 3 per cent. died from acute hæmorrhage and Mr. Robson did not say that these could be saved, but the other 3 per cent. died as a result of chronic hæmorrhage, and these cases could be saved by surgical means. Gastro-enterostomy acted as a drain to the stomach; it put a stop to the vermicular action of the stomach and checked hyperacidity. The operation gave almost absolute physiological rest.

The PRESIDENT conveyed the hearty thanks of the society to Mr. Mayo Robson for coming to Edinburgh and giving such an interesting communication.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—A meeting of this society was held on Jan. 31st at 20, Hanover-square, W., Dr. Frederic Bagshawe (St. Leonards), the President, being in the chair.—The President referred in feeling terms to the death of Her Majesty Queen Victoria and proposed the following vote of condolence with His Majesty King Edward VII., which was passed unanimously:—

The Fellows of the British Balneological and Climatological Society in meeting assembled humbly approach Your Majesty with the expression of our deep sorrow at the loss sustained by Your Majesty, the Royal Family, and the nation by the death of our beloved Sovereign, Queen Victoria.

—Professor Clifford Allbutt, in opening a discussion on Anæmia and its Therapeutics, said that he undertook the task allotted to him with more than diffidence because there were among his hearers many who were far more versed in the management of anæmias by climatic and bath treatment than himself. Nevertheless, he would urge that the discussion should be confined to the treatment of these diseases by physical means or otherwise it might wander over too large a sphere to be useful. What latitude was to be given to the name of anæmia? The first division Professor Allbutt proposed was that into simple anæmias and hæmolytic anæmias, the former being indicative of some nutritive or physical deviation and the latter of the presence of a toxic cause of deterioration, such as the cachexias of lead, of tubercle or cancer, and so forth. Yet even this distinction could not be pressed, as in some anæmias supposed to be simple there might be a latent toxic cause, as, for instance, was alleged by some observers in chlorosis. In the consideration of the simple anæmias they were now deprived of some of the help which they believed themselves to possess, for a superficial drop of blood as taken for microscopical examination was by no means always, or even generally, an average specimen of the whole blood. Furthermore, the bulk of the blood mass in the body turned out, not unexpectedly, to be a factor of considerable importance. At last this factor, as it would seem, could be measured by the method of Haldane and Lorrain Smith, of which Professor Allbutt gave a brief account. From these researches it had been stated that in all anæmias there was an increase of the blood mass, or in all simple anæmias, but to clinical observers this seemed a very wide proposition. It was, however, in accordance with ordinary experience that the blood mass should prove to be increased in chlorosis. Professor Allbutt had been of opinion that in ordinary anæmias, such as that of convalescence from acute disease, that of hæmorrhages, and that which was common in (and even characteristic of) ill-nourished persons, there was a reduction of the blood as a whole, corpuscles and plasma. In chlorosis, on the other hand, the dilatation of the heart, and the voluminous, if not high-pressure, pulse seemed to signify increased blood bulk. How iron cures chlorosis was a deeper mystery than ever, as it could no longer be believed that it did so by building up hæmoglobin, but if an excess of plasma were a fault in chlorosis, removal to high altitudes would seem to be a better adjuvant in treatment than the use of spa waters, which would have the disadvantage of adding to the bulk of blood already excessive. Professor Allbutt then drew attention to the interesting work which had just appeared by Dr. George Oliver, in which were recorded many long and laborious series of observations on the composition of the blood (as also of blood-pressures) under varying conditions. Among other deductions from his observations was an explanation of the well-known apparent increase of red corpuscles in persons removed to high altitudes—namely, by a concentration of the plasma. In this view the increase was not absolute but relative. Dr. Oliver ascertained that the concentration of the plasma was due not to elevation as such, but to a greater dryness of climate; and in proof of this position he found that further experiments carried on in dry climates such as Egypt, though at sea-level, produced the same apparent increase of red corpuscles—that was, the same concentration of plasma. Professor Allbutt urged that chlorosis in the discussion should be distinguished from the anæmia of ill-nourished or impoverished persons which needed other means of treatment. Starvation anæmia was found in both sexes, but chlorosis was peculiar to women. It would not do, therefore, to take all anæmias occurring in women as chlorosis, whereby many mistakes would become current—e.g., the anæmia of arterial "hypoplasia" was not chlorosis; it was found in both sexes and was not attended by increase in the bulk of the blood.—Dr. G. A Leon (Sidmouth) said that chlorosis was very prevalent in the South Devon valleys, where the relative humidity was high. The majority of the sufferers were domestic servants, but there were also many work-girls and girls living at home. No deficiency of light, air, or food was to be noticed in the history of the cases. The teeth of the youth of South Devon were deplorably defective and no doubt this was a factor in the causation of the disease. It was interesting to observe the relationship of climate to chlorosis and the hæmorrhages—e.g., menorrhagia. To both classes of disease a damp locality and low altitude were unfavourable, but yet the chlorotic patient did not menstruate at all as a rule, and if she did the loss was but scanty.—Dr. Sansom said that he had seen some cases of chlorosis where the heart seemed to be dilated and others in which it was apparently diminished, but the physical signs, especially over the apex, were the same in both cases. He thought that in the majority of chlorotics the heart was smaller than normal. He considered that the pulmonary artery was often narrowed by hyperplasia of the vessel and said that in such cases climatological and balneological treatment would prove useful. Chlorotic patients should breathe the best oxygenated air and be induced to practise respiratory exercises.—Dr. William Hunter said that Professor Allbutt had emphasised the fact of the variability in composition and constitution of the blood, and he (Dr. Hunter) would allude to another feature perhaps even more important—viz., the remarkable stability of the blood, not only of its corpuscles but of its plasma, under the most diverse and unfavourable influences, so that anæmia could be divided into two great classes. The first was that associated with all sorts of wasting diseases, and in that form the anæmia was very slight. Starvation or deprivation of food caused little change in the blood though it diminished its bulk, as it did that of ordinary muscle. The other class of factors affecting the blood was that which Professor Allbutt had very properly drawn special attention to—changes far in excess of those caused by nutritional variations—i.e., changes in the proportion of corpuscles, in the proportion of hæmoglobin, and in the fluid. Such anæmia was exemplified by the disease known as chlorosis but still more so in the toxic anæmias or hæmolytic anæmias, the agencies of which were of a totally different character.—Dr. Ewart said that clinical confusion was apt to occur between the cases of true chlorosis and those of anæmia in working girls due to dyspepsia and malnutrition from tender and decaying teeth. The latter form remained refractory to

treatment and apt to relapse so long as the cause was overlooked and unrelieved. Among the pyrexial cases sometimes occurring in young women he had for some years recognised two groups; in the much larger group the pyrexia was simply due to the results of dental disease, in the much smaller group the cause was not obvious and this might for the present be distinguished as the group of true pyrexial chloro-anæmia.—Dr. Collins and Dr. W. V. Snow (Bournemouth) also spoke.—The meeting was adjourned to March 15th.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on Jan. 30th, Dr. Robert Jardine, the President, being in the chair.—The President showed a case of Opacity of the Cornea in the New Born. After birth the right cornea was noticed to be hazy, getting denser towards the centre. The pupil was difficult to distinguish, but reacted to strong light. Examination showed irregularity of surface epithelium of the cornea, while the underlying tissue had discrete spots of a fluffy appearance closely packed together. No vessels or tracts of such were seen. The opacity gradually cleared and on the seventh day when shown at the meeting was only visible at one side. The condition was probably due to compression of the eyeball during parturition, as the right upper eyelid and the right temple were bruised.—Dr. J. Edgar showed specimen and read notes of a case of Complete Tubal Abortion in which the intact three weeks' old ovum was found lying in the pouch of Douglas. The patient, aged 30 years, a nullipara, was admitted to the Samaritan Hospital in a collapsed condition and complaining of pain most severe in the left iliac region. The abdomen was distended and tender and a soft boggy mass was felt per vaginam behind the uterus. The abdomen was full of blood and the left tube was dilated at the outer end to the size of the index finger and was patent. The patient made a good recovery.—The President and Dr. Munro Kerr each read notes of cases of Sudden Death in the Puerperium from Pulmonary Embolism. In one case the heart was shown with a large ante-mortem clot in the right ventricle extending up into the pulmonary artery.—The President read a paper on a rare case of Spontaneous Rupture of the Uterus occurring without warning and no obstruction to labour. The patient, a woman, aged 32 years, vii.-para, was brought into the Glasgow Maternity Hospital at 11 A.M. on Jan. 26th, 1900, owing to hæmorrhage early in the first stage. Dr. Jardine examined her one and a half hours after admission. The bleeding had ceased, the pains were good and increasing in force, but the patient complained of pain low down at the left side of the abdomen. The child presented in the first position. The uterus was not overdistended and showed no signs of internal hæmorrhage. The cervix was of the size of a crown piece; the membranes were intact. Labour seemed to be progressing naturally, so nothing was done. At 2 P.M., three hours after admission, the patient had a violent pain and screamed out that something had given way. She had three violent uterine pains in quick succession and then collapsed completely. The resident, Dr. W. F. McEwen, found the os fully dilated and intact and the head engaged. He delivered with forceps without difficulty and the birth of the child was followed by a quantity of blood-clot, the placenta being removed at once. A large tear was now noticed involving the cervix and extending upwards in the long axis of the uterus to near the fundus. The rent was plugged with iodoform gauze and a saline infusion and stimulants were given, but the patient died in a few minutes, just as Dr. Jardine arrived. Dr. A. R. Ferguson, pathologist, made a histological examination of the uterus. The muscular fibres were degenerated at the seat of the rupture, many being swollen and hyaline in appearance, and nuclear staining practically absent. Similar appearances were noticed at a distance from the seat of the tear. The muscle fibres at the seat of the tear were for the most part atrophied and shrunken and in many places showed transverse or irregular fractures of muscle substance, nuclear staining being absent. The elastic tissue fibres were relatively scanty near the ruptured edge and stained more feebly than elsewhere, whilst many were broken up and presented slight irregularity of contour. Dr. Jardine referred to a similar case occurring five years ago in a nullipara, there being also no obstruction to labour to account for the rupture. He also referred to a case reported by Dr. Michael Poroschin in the *Centralblatt für Gynäkologie*, February, 1898, which was at first diagnosed as one of accidental hæmorrhage. Dr. Jardine thought that the hæmorrhage in his own case might have been due to incomplete rupture, as in Dr. Poroschin's, since the patient complained of pain in the left side, and that later the tear extended and became complete, the involvement of the cervix being due to forceps delivery. A case of Hindle's was reported in the *British Medical Journal* of Feb. 10th, 1894, where the elastic tissue was almost entirely absent, and rupture was ascribed to this. Such cases of rupture could not be avoided, as there was no obstruction to labour and no warning till it actually happened.—Dr. A. W. Russell read notes of a case of Placental Polypus after Full-time Labour and showed the specimen which was of the size of a small hen's egg. There was more or less persistent hæmorrhage in the puerperium and the polypus being discovered as the cause was removed.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 31st, Dr. Wearne Clarke, the President, being in the chair.—Dr. G. Wilkinson showed a boy, aged 10 years, suffering from Spontaneous Dislocation of the Hip occurring during enteric fever six months previously.—Dr. A. Rayner showed (for Dr. J. W. Martin) an Ovarian Sarcoma removed from a girl, aged 17 years.—Mr. S. Snell introduced a man, aged 36 years, from whom he had removed an Encapsuled Spindle-celled Sarcoma from the floor of the orbit.—Mr. Snell showed the specimens from a case of Sarcoma of the Choroid recurring in the orbit. In July, 1897, the sclerotic was punctured for detached retina. At this time if a sarcoma was present it must have been very small and have escaped detection. In November, 1898, the patient was again seen, when the eyeball was filled with an intra-ocular growth (sarcoma). When seen next, in the early part of May, 1900, the growth was springing from the orbit, chiefly its floor. This was removed and the orbit was cleared out, and chloride of zinc paste was applied, since which time there had been no recurrence. The patient was a man, aged about 60 years. The tumour was a large round-celled sarcoma.—Dr. S. White showed the following cases:—1. Two women with Unusual Breast Tumour. 2. A woman from whom he had removed the Right Upper Maxilla for Sarcoma. 3. A youth the subject of Paralytic Talipes Equinus whose tendo Achillis had been divided into three vertical slips, two of which had been utilised for lengthening the contracted tendon, while the third slip was brought subcutaneously to the front above the outer melleolus and attached to the extensor of the toes. The patient was able to flex the ankle-joint and the deformity was entirely overcome. 4. Seven cases of Resection of the Knee-joint for disease. In each case the synovial membrane, the patella, and all diseased cartilage and bone were removed and the femur and tibia were united by two silver-wire sutures. No drainage was employed but the posterior half inch of the skin wound on either side was left open. Rigid asepsis was enforced and in all the cases the wound healed without suppuration under the first dressing. Bony union had taken place in all. 5. Three cases of Gastro-enterostomy for Fibrous Stricture of the Pylorus with Gastric Dilatation. In all three symptoms of obstruction had been present for upwards of two years and had been entirely removed by operation. In one case the patient had had three attacks of gastric tetany. The method of operating had been to implant the upper end of the jejunum on the anterior surface of the stomach by simple suturing without any mechanical support.—Dr. H. Peck read a paper on an Outbreak of Diphtheria in a Boarding School considered with regard to the Value of Bacteriological Examination. The school, which was well situated, dry, and in good sanitary condition, had about 50 boarders and 50 day scholars. On Oct. 5th two boarders complained of sore-throat and bacteriological examination showed the presence of diphtheria bacilli. The day school was dispersed and one boarder, A B, was allowed to return to her home on the understanding that she would not be allowed to return to school until swabbings had been taken from her throat and found satisfactory. A third case occurred on Oct. 8th. Swabbings were taken from the throats of all the boarders, boarding teachers, and domestic servants, and on Oct. 13th all boarders who had shown negative results were removed to another house, while the three patients and two who had shown positive results, though they exhibited no symptoms, were separately isolated. On Nov. 5th all the scholars, with the exception of A B, reassembled at the school which had been carefully disinfected. All the boarders showed a clean bill of health bacteriologically. A B returned on

Nov. 12th, went home on the 16th, and on the 19th was reported to be suffering from diphtheria. It then transpired that this patient's throat had not been examined bacteriologically, though she had been using an antiseptic throat wash. On the 18th five other boarders were suffering from slight ailments and were removed to the second house. In these cases bacteriological examination gave three positive and two negative results. Swabbings were then taken from all the boarders and day scholars, with the result that 28 showed the presence of diphtheria bacilli and the school was "broken up," only the children who gave positive results being detained. Dr. Peck emphasised the immense value of systematic bacteriological investigation in cases of suspicious sore-throat. It was well known that diphtheria might be transmitted by individuals in perfect health but who nevertheless carried the bacilli in their throats. One such case occurred in this outbreak. An interesting point was the length of the incubation period in the case of A B, which was nearly five weeks.

OTOLOGICAL SOCIETY OF THE UNITED KINGDOM.—A meeting of this society was held on Feb. 4th, Sir W. B. Dalby, the President, being in the chair.—It was resolved that the following address be presented to His Majesty the King:—

May it please Your Majesty, we, the President and members of the Otological Society of the United Kingdom, in meeting assembled this day, beg dutifully and humbly to offer to His Majesty King Edward VII., and to the other members of the Royal Family, their profound and heartfelt sympathy on the occasion of the death of our beloved Queen Victoria, and to assure His Majesty of their feelings of loyalty and devotion to his throne and person.

—Dr. Dundas Grant showed two patients upon whom he had performed a radical mastoid operation for Cholesteatoma with preservation of the lining membrane and with Korner's plastic flap. In the first case, that of an elderly woman, the cholesteatomatous débris was scraped away but the lining membrane was left. He hoped that the lining membrane would serve as a fair substitute for the pseudo-epidermic lining which they endeavoured to secure in such cases. The second case was treated in a similar way.—Dr. Milligan showed a male patient on whom the radical mastoid operation had been performed for chronic suppurative disease of the epi-tympanum and adjoining mastoid cells. The antro-tympanic cavity had been successfully grafted. The result was good, complete healing having taken place within four weeks. The amount of improvement in hearing capacity was very remarkable, especially in regard to the power of hearing conversation.—The President said that the result was so excellent as to leave little to be desired.—Mr. P. de Santi showed a patient upon whom an operation had been performed for cholesteatoma and another patient who had been operated upon for mastoid disease with gangrene of the deep soft structures and emphysema of scalp tissues.—Dr. StClair Thomson showed a patient upon whom ossiculectomy had been performed for "attic" disease.—Mr. C. A. Ballance read the notes of a Fatal Case of Temporal Bone Pyæmia. At the necropsy the pars petrosa and a portion of the occipital bone were in an advanced state of decay. No secondary pyæmic deposits were found anywhere in the body.—Dr. Adolph Bronner showed a Microscopic Section of an Epithelioma of the Cutaneous External Meatus which was at first mistaken for mastoid disease, and made some general remarks upon malignant disease of the external auditory meatus which he did not consider to be so very rare as was usually supposed, he himself having seen five or six cases within the last few years.—Mr. Ballance considered such cases rare, as also did Dr. MacNaughton Jones.—The President remarked that he had only seen one such case before.—Dr. Urban Pritchard said that he had seen very few cases of malignant disease arising in the tissues of the external meatus.—Mr. A. H. Cheatle and Dr. Milligan showed specimens of Tuberculosis of the Middle Ear.—The President related the case of a Bullet Wound through the Brain and Cerebellum, leaving no after-effects beyond loss of hearing upon one side.

MIDLAND MEDICAL SOCIETY.—The fifth ordinary meeting of this society was held on Jan. 30th, at the Birmingham Medical Institute, Dr. Jordan Lloyd, the President, being in the chair.—Mr. Gamgee showed a girl, aged 12 years, who had in the beginning of November, 1900, suffered from very severe symptoms, indicating some intracranial mischief due to middle-ear disease. There had been suppurative otitis media present for two years. The only localising symptom was tenderness over the left mastoid. The left side was explored with a negative result. Five days afterwards the right side was explored and one ounce of pus was let out from between the bone and the dura over the right lobe of the cerebellum. The patient made a good recovery.—Dr. Thomas Wilson showed a Parovarian Unilocular Cyst with Twisted Pedicle and a Retroverted Myomatous Uterus removed by abdominal hysterectomy.—Mr. Haslam showed a Renal Calculus, weighing 489 grains, that he had removed from the right kidney of a man, aged 33 years, and one, weighing 1289 grains, that he had removed two months later from the left kidney of the same patient. Symptoms had been present for 18 years.—Mr. J. Furneaux Jordan showed a specimen of Myoma of the Uterus (invading the broad ligament) with Hydrosalpinx. The specimen consisted of the uterus, containing in its interior a submucous fibroid and in its outer wall a small subperitoneal fibroid, and of a large myoma growing from the left side of the uterus, spread out on the top of which was a large pear-shaped hydrosalpinx. The operation performed was that of combined hysterectomy. On opening the abdomen with the patient in the Trendelenburg position the tumour in the broad ligament was shelled out from the broad ligament, the ovarian and uterine vessels were tied outside the tumour, and then the right broad ligament was ligatured between the uterus and the appendages. In this way the uterus, the myoma, and the hydrosalpinx were removed, while the right appendages were left behind. The ligatures were cut short and a gauze drain was carried into the vagina. The patient, whose age was 39 years, had been married for 22 years and had had two children, the youngest of whom was 20 years of age. For the last two years she had suffered from severe hæmorrhage and for five months continuously the loss had never ceased. Latterly there had been considerable pain. She was a very stout woman, absolutely blanched from hæmorrhage, and with a small, feeble, rapid pulse. Her recovery had not been perfect, as she had a stitch abscess. The operation was performed three weeks ago and she was now well.—Dr. W. J. McCardie exhibited Breuer's Inhaler for the administration of ethyl chloride.—Dr. Stacey Wilson read a paper on Intestinal Obstruction Amenable to Non-operative Treatment.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—A meeting of the Section of Surgery was held on Dec. 7th, 1900, Dr. T. Myles, the President, being in the chair.—Mr. Alexander Blaney made a communication on the Removal of Great Lengths of Intestine. He first detailed the notes of a case which had been operated on by Dr. P. J. Hayes at the Mater Misericordiæ Hospital. A boy, aged 10 years, who was brought to that institution had been run over by a wagon carrying a ton and a half of grain. The wheel passed over his lumbar region while he was lying on his face. Laparotomy was performed 17 hours after admission. The intestine was found extensively crushed, and in addition there was a long transverse rent in the mesentery. The damaged gut was removed and was found subsequently to measure eight feet four and a half inches. The boy recovered and was exhibited. He now suffered from looseness of the bowels and occasional vomiting. His appetite was abnormally great. The second part of the paper gave the results of experiments on animals in which great lengths of intestine had been removed, and an analysis of 33 cases in which over one metre of intestine had been removed in man. The conclusion drawn from these cases was that when the bowel removed was less than 200 centimetres (six feet six and a half inches) intestinal symptoms were, as a rule, absent; when more was removed intestinal symptoms were present. Children apparently stood great resections better than did adults.—The President said that the paper was one of the most interesting communications ever made to that section of the Academy. If they had not seen the patient they could scarcely have believed that a wagon bearing a load of one and a half tons could have passed over him without crushing him to death; yet apparently it produced only laceration of the mesentery. The case also illustrated the extreme difficulty of accurate diagnosis—a difficulty which was increased in the present instance by the fact that the intestine was not ruptured.—Professor E. J. McWeeney said that the very swollen appearance of a good deal of the resected portion of the gut seemed to be due to hæmorrhage into the coats, but the microscopic examination showed that the hæmorrhage was in reality slighter than the naked-eye appearance indicated. The microscope showed congestion

of both the lymphatic vessels and the blood-vessels and the most striking œdema of the coats of the intestine which he had ever seen. A point which struck him in examining a series of sections was what he might describe as the asepticity of the removed bowel. The micro-organisms were few and far between and there was no tendency to migration into the peritoneal cavity.—Mr. J. Lentaigne, Professor White, and others also discussed the case.

FOLKESTONE MEDICAL SOCIETY.—A meeting of this society was held on Feb. 1st, Dr. W. J. Tyson, the President, being in the chair. The rules of the society were revised and a committee was re-appointed "to investigate the therapeutic resources of Folkestone with special reference to the baths." Mr. F. A. Osborn of Dover was elected a member.—Dr. W. L. Chubb showed a specimen of an Anencephalic Fœtus.—Dr. Cecil Latter read a paper on the Physical Signs of Acute Pulmonary Disease. He drew attention to the necessity of differentiating between the physical signs in adults and children. The presence of fluid, for example, in a child's pleura was not always accompanied by the physical signs produced by pleuritic fluid in an adult. This was especially the case with small empyemas occurring in children. They were more often deduced from the clinical course of the disease than diagnosed by any typical signs. Another point of difference between adult and infantile chests was the more frequent absence of all physical signs in the case of children in the earlier stages of acute pulmonary attacks. A child suffering from severe broncho-pneumonia might exhibit no physical signs until the temperature was normal and the breathing was quiet. He next referred to the physical signs of pleurisy with effusion and their value in determining the proper time for aspiration. He strongly advocated the measure while the amount of the fluid was still moderate. The paper concluded with an account of some cases at the Victoria Hospital (Folkestone) bearing upon the subject.—A discussion followed in which Dr. T. Eastes, Dr. Chubb, Dr. P. G. Lewis, Dr. L. Wainwright, Dr. A. E. Larking, Mr. W. F. Chambers, Mr. W. P. Barrett, and the President took part.

ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—At the meeting of this society held at Guy's Hospital on Feb. 8th Professor A. H. Young, the President, before proceeding with the business of the meeting, proposed the following motion:—

That the members of the Anatomical Society of Great Britain and Ireland desire to record their profound grief at the death of Her Most Gracious Majesty Queen Victoria, and their deep sense of the great influence the Queen exercised on all that made for good and progress. In particular the society gratefully recalls the Queen's interest in the advancement of science. The society desires further to offer to His Majesty King Edward VII. a dutiful assurance of unswerving and devoted loyalty to his throne and person.

Mr. R. Clement Lucas (Vice-President), in seconding the motion, said that in these days of universal grief and of national mourning little need be added to the remarks of the President to express the loss the members of that society felt they had sustained by the death of their beloved Queen or to record their respectful sympathy with the Royal Family. He had been chosen as a member of the staff of Guy's Hospital to second the motion because the meeting was being held in Guy's Hospital, a hospital which had benefited by the interest His Majesty King Edward VII. had taken in it and by the great honour he had bestowed upon it by accepting the position of President. The members of the society were loyally and devoutly attached to the throne and he had little doubt that His Majesty the King would show the same interest in the advancement of science as had been evinced by his revered and Royal mother.—The members signified their unanimous acceptance of the motion by standing.

MEDICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on Feb. 6th, Mr. Alexander Wilson, the Vice-President, being in the chair.—Dr. D. McKeown in Observations on 2000 Operations for the Removal of Post-nasal Adenoids pointed out that an exaggerated diagnostic importance was attached to the "characteristic facial aspect"; the stage should not be the dominating factor in determining treatment; that certain symptoms described as reflex might be otherwise explained; that wherever adenoids were found with affections dependent on unstable conditions of the nervous system operation was indicated; that the rarity of incontinence of urine was probably only apparent; that "imperfect aeration of the blood" was insufficient to explain the symptoms put to its account; and that the teaching in regard to auditory results of operation had to be supplemented by two facts—immediate improvement and a possible ultimate impairment.—Mr. C. E. Richmond made a short communication on Biliary, Vesical, and Prostatic Calculi, showing the specimens, which included a vesical calculus weighing nine and a quarter ounces.—Dr. Brooke read a paper on the Skin Eruptions found in Arsenical Poisoning. The paper was illustrated by means of lantern photographs.

ROCHDALE AND DISTRICT MEDICAL SOCIETY.—A meeting of this society was held on Feb. 7th.—Dr. J. Melvin read a paper on Spasmodic Asthma, illustrating various points by references to cases in his own practice. He dwelt especially on the treatment, pointing out with regard to climate that a suitable locality for any individual case had to be discovered experimentally. Diet was important. Many drugs might have to be tried in succession ere the most useful was hit upon.—Dr. A. Wallace, Mr. G. W. Malim, Mr. W. Stanwell, Mr. J. P. Walker, and Dr. E. Sugden discussed the paper.

Reviews and Notices of Books.

Text-book of the Embryology of the Invertebrates. By Dr. E. KORSCHELT of Marburg and Dr. K. HEIDER of Berlin. Translated from the German by MATILDA BERNARD. Revised and edited, with additional notes, by MARTIN F. WOODWARD, of the Royal College of Science, London. Vol. IV. London: Swan Sonnenschein and Co., Limited. 1900. Pp. 594. Price 18*s*.
